<b>ACETO-CELLULOSE</b> ... ..	532	Birassol ... ..	124	Colour Photography, Application of the Diffraction	
Acetone in the Developer. By J. Bardwell ...	813	Bird Photography. By J. A. Reid ... ..	731	Grating to. By Prof. R. W. Wood ... ..	229
Acetone, Testing for ... ..	340	Birmingham Exhibition ... ..	137	Colour Photography at the Camera Club ...	649
Acetylene ... ..	382, 627, 655	Birmingham International Exhibition ...	77, 202	Colour Photography. By Philip E. B. Jourdain ...	232
Acetylene at Low Temperatures ... ..	180	Blacklead Pencils ... ..	405	Colour Photography, Cameras for ... ..	762
Acetylene Explosions ... ..	157	Blue Prints ... ..	615	Colour Photography, Diffraction Process of. By	
Acetylene for Photo-micrography ... ..	677	Blue Prints and Photo-zincography ... ..	630	Prof. R. W. Wood ... ..	420
Acetylene, Purification of ... ..	4, 131, 484, 771	Bolton, the late W. B. ... ..	316	Colour, Photography of. By E. Sanger Shepherd ...	583
Acetylene Residue ... ..	238, 448	Bradford Exhibition ... ..	187	Colour-sensitising Plates ... ..	117, 182
Actinism, Measurement of ... ..	11	Brasswork ... ..	598	Colson-Russell Effect, Phenomena Corrected with.	
Action of Light at Low Temperatures ... ..	262	Brasswork, Preserving from Corrosion ...	771	By J. H. Vincent ... ..	423
Action of Light on Metallic Silver. By Major-General		British Association ... ..	556	Combined Bath ... ..	703, 718
Waterhouse ... ..	645	BRITISH JOURNAL OF PHOTOGRAPHY and the Crystal		Combined Development and Fixation ... ..	311, 520
Actinograms. By J. A. Randall ... ..	426	Palace Exhibition ... ..	380	Combined Toning and Fixing ... ..	263, 515
Actinometers ... ..	798	Broadland ... ..	491	Composition and Breadth ... ..	358
Actinometers, Explosive ... ..	132	Bromide Printing, Hints on ... ..	789	Convention, A Stranger at. By A. Scotsman ...	459
Adnol ... ..	139, 184, 378, 473, 553	Bromide Prints, Finishing ... ..	566	Convention, Gloucester ... ..	150
Affiliation of Photographic Societies ... ..	56, 62, 364	Bromide Prints, Reduction of ... ..	598	Cooke Lens ... ..	238
"Agfa" ... ..	331, 428	Bromide Process, Permanence of ... ..	543, 563, 611	Cooke Lens, Improvements in ... ..	199
Albumen and Gelatine Papers. By E. Dunmore ...	133	Bromides, Purity of ... ..	660	Coppering a Negative ... ..	842
Albumen, Coagulation of ... ..	51	Bromised Developing Agents ... ..	376	Copper Plates, to Steel ... ..	631
Albumen Prints, Permanent ... ..	792, 820	Bronzes in Photography ... ..	754	Copper Salts, Light-sensitive ... ..	375
Albumen versus Gelatine ... ..	147	Burnett's Combined Music and Camera Stand	70	Copyright ... ..	559
Albums, Dalton's System ... ..	41	Burton, the late Prof. W. K. ... ..	603	Copyright Bill ... ..	260, 275, 325, 371, 398
Alkaline Chromates, Solutions of ... ..	263	By the Way. By Dogberry ... ..	4	Copyright, International ... ..	356
Almanac (The), Advertisements and Savages. By				Copyright in Trade Catalogue Illustrations ...	509
Zwittau ... ..	806	<b>CADETT Orthochromatic Light Filter</b> ... ..	268	Copyright Law, New Points in ... ..	726
American Camera Combination ... ..	728	Cadett P.O.P. ... ..	12, 93	Coronagraphy, Exposures in ... ..	236
American Editor in London ... ..	681	Cadett Safe Light ... ..	12	Corona, Photographing the ... ..	84
Alpine Club's Exhibition ... ..	234	Calcic Carbide ... ..	174	Corona, Photographing without an Eclipse ...	196
Alpine Photography ... ..	298	Calcium Paper ... ..	268	Cristoid Film ... ..	766, 776, 830
Aluminium ... ..	4, 85	Camera Club, Mr. E. R. Ashton at the ...	650	Croydon Camera Club Exhibition ... ..	682
Aluminium. By C. T. Sutton ... ..	633	Camera for Three-colour Printing ... ..	173	Crystals, Photographing ... ..	531
Aluminium, Deterioration of ... ..	468	Camera in the Battlefield ... ..	203	Cryteolum ... ..	172, 715
Aluminium Microscope Stand ... ..	142	Camera, Siegrist's New ... ..	525	Current Photographic Topics. By A. C. Beard ...	712
Aluminium, Permanency of ... ..	276	Carbide of Calcium, Properties of ... ..	52	Cutting Prints, Machine for ... ..	601
American Dry-plate Making. By W. F. Miller ...	482	Carbon Printing, Over-exposure in ... ..	104	Cyanide Poisoning ... ..	628, 644
Ammoniacal Nitrate of Silver ... ..	580, 607	Carbon Tissue, Sensitising ... ..	50	Cyanide, Poisoning by ... ..	163
Ammonium Persulphate ... ..	68, 103, 148, 230, 277, 294,	Carriers and Cat Films. By J. Pike ... ..	539	Cyanine as a Sensitiser ... ..	38
	311, 356, 439, 486	Cathedral Hand Camera ... ..	383	Cyanotype ... ..	406
Anastigmat, A New ... ..	501	Cathode Rays ... ..	580	Cycling with the Camera. By J. Pike ... ..	440
Anastigmats, The Origin and History of Certain. By		Celluloid ... ..	499	<b>DAGUERREOTYPES, Restoration of. By C. B.</b>	
D. P. Turnbull ... ..	550, 532	Celluloid for Measures ... ..	392, 431	Barnes ... ..	120
Animated Photography ... ..	174, 191, 636, 667	Celluloid, Non-inflammable ... ..	4	Daguerreotype, Teachings of. By Major General	
Animated Photography, Apparatus for ... ..	140	Celluloid, Rival to ... ..	771	Waterhouse ... ..	740, 756
Apparatus, Cheap. By J. Pike ... ..	517	Celluloid Varnishes ... ..	243	Dallmeyer Focometer ... ..	796
Apparatus Overhauling ... ..	165	Cheap Enlargements ... ..	142	Dark Lighting ... ..	599
Architectural Photography ... ..	69, 653, 749, 810	Chemist as Photographic Dealer ... ..	171	Dark Room, Abolishing the ... ..	80
Armstrong's Guide to Practical Photography ...	138	Chemistry of Photography. By C. T. Sutton ...	281	Dark Room, Abolishing the. By G. Howard Farmer ...	39
Art for Photographers ... ..	328	Chemistry of Photography in Relation to Develop-		Dark Room Illumination ... ..	355
Artistic Copyright ... ..	427	ment. By J. B. Readman ... ..	807	Dark Rooms, Healthful ... ..	196
Art Principles in Photography ... ..	282	Chlorate of Potash Explosion ... ..	307, 356	Daylight Changing System, Hett's ... ..	443
Asphalt Process, New ... ..	534	Chloride, Iodide, and Bromide of Silver, Separation		Daylight Developing Apparatus ... ..	813
Assistants and their Future ... ..	179	of Mixtures of ... ..	115	Dekko Paper ... ..	92, 186
Astronomical Camera, Lens for ... ..	628	Chloride of Gold ... ..	115	Derby Exhibition ... ..	300, 374
Atmosphere ... ..	691	Chromo Camera ... ..	358	Developers and their Modification ... ..	270
Aura Self-toning Paper ... ..	428	Cinematograph Accident and the L. C. C. ...	163	Developers, Non-actinic Apparatus for ... ..	393
Autumn and Autumn Work ... ..	597	Cinematography, Liquid Prisms in ... ..	570	Developers, Old and New ... ..	383
Avery Backing Tray and Pad ... ..	235	City and Guilds Examinations ... ..	555	Developers, Reducing Powers of ... ..	535
Axe Brand P.O.P. ... ..	429	"Climax" Albumenised Paper ... ..	187	Developing and Changing Tent ... ..	411
<b>BACKGROUNDS, Mounts, and Frames. By J. H.</b>		Cloud Photographs ... ..	452, 541, 726	Developing Kodak Film Uncat ... ..	491
McFarland ... ..	278	Clouds. By W. J. Croall ... ..	565	Developing Printing-out Paper, Mayall's System of ...	427
Backing Plates ... ..	194	Clouds, Printing in ... ..	759	Developing Solution, Repeated use of ... ..	567
Balloon Photography ... ..	278	Cobalt, Action of Light on ... ..	475, 488, 521	Development after Fixation ... ..	149
Barnet Extra Rapid Plates ... ..	78	Cobalt, Action of Light on Salts of ... ..	295	Development, Fundamental Points Concerning. By	
Barnet Works ... ..	619	Coins as Units of Weight ... ..	532	C. H. Bothamley ... ..	453
Bas Relief Photography ... ..	335, 364	Colloid-chloride versus Gelatino-chloride ...	504	Development, Intensification and Fixing in One Opera-	
Becquerel's Rays ... ..	116, 340	Colloidion Negatives, Intensifying ... ..	501	tion. By W. B. Bolton ... ..	20, 52
Benevolent Committee ... ..	92	Colloidion Paper, Blue Tones on ... ..	311	Development of P.O.P. ... ..	57, 60, 66
Benzole, Deodorising ... ..	82	Coloured Screens ... ..	198, 676	Development, Principles of ... ..	716, 735, 761
Benzole, Purification of ... ..	82	Coloured Screens, Testing ... ..	496	Development, Rapidity of. By A. F. von Hahl ...	519
Bethel's Dark Slide ... ..	220	Colour Fallacies ... ..	114, 190, 226	Development Without Light. By A. Watkins ...	471
Big "D." By E. Dunmore ... ..	634	Colour Facts and Fallacies ... ..	290, 322	Diffraction, Grating Colour Photography ... ..	357, 45
Binocular Photography ... ..	223	Colouring Photographs ... ..	489	Diffraction of Röntgen Rays ... ..	27
Binocular Vision and the Stereoscope. By Thomas		Colouring Photograph <sup>1</sup> By O. Thornberry ...	634	Doubtful Tendencies. By Horace Mammery ...	646
Bedding ... ..	455	Colour Photography ... ..	118, 142, 302	Dry Mounting ... ..	

Dry Plates and their Manufacture ... ..	181	Gold (Metallic), Aqueous Solution of ... ..	340	Kromskop Portraiture. By Lt. L. Walker Munro ...	214
Duplication of Negatives, Essentials in... ..	351	Gold, Precipitation of, by Charcoal ... ..	244	Krugener's Improved Roll-holder ... ..	26
<b>E</b> BONITE Shutters ... ..	38	Gold Reduction, Novel Mode of ... ..	213	<b>L.</b> & P. Supper." By A. Guest ... ..	106
Eclipse of the Moon ... ..	36	Gold Toning with Sulphocyanide. By C. L. Hett ...	11	"L. Lao and its Solutions ... ..	498
Eclipse Photograph at the R.P.S. Exhibition ...	656, 671, 702, 718, 767, 783	Graining Photographic Screens, Haas' Method of ...	221	Lady in the Reception Room ... ..	316
Edinburgh Exhibition ... ..	91	Graphic Competition ... ..	234	Landscapes and Clouds ... ..	680
Electric Lighting for Portraiture ... ..	792	Gravura ... ..	57, 93, 94, 107, 790, 797	Langier Studios ... ..	603
Electric Lighting, Promised Revolution in ...	116	Gravura Opals ... ..	780	Lantern Manipulation ... ..	94
Electric Transmission of Photographs ... ..	252	Greenwich Visitation ... ..	884	Lantern-slide Developer, Pyro as ... ..	141, 157
Elementary Ophthalmics ... ..	89	Griffin's Acid Hypo Cartridges ... ..	58	Lantern-slide Making, Stale Plates in. By A. T. Newton ...	121
Elementary Perspective and Composition ...	793	Groun Glass, Extra Fine ... ..	36	Lantern Slides, Colouring of ... ..	724
Emerson, Dinner to Dr. P. H. ... ..	650	Gum-bichromate Process ... ..	68, 89, 487, 677	Lantern Slides, Plea for Pyro in Development of. By T. N. Armstrong ...	11
Emulsions, Preparation of with the Aid of Electricity	534	<b>H</b> ACKNEY Exhibition ... ..	745	Lantern Slides, Warm Tones in ... ..	535
Enlarging, a Neglected System of ... ..	419	Halation and Backing ... ..	46	Large Telescopes, Does it Pay to Build ... ..	413
Enlarging Simplified ... ..	746	Half-tone Process for Aluminium or Zinc Printing ...	36	Latent Image ... ..	436
Exeter Exhibition ... ..	621	Half-tone Screens ... ..	44	Latent Image. By Dr. R. Luther ... ..	664
Exhibition at Edinburgh ... ..	665	Half-tone Screens, Automatic Adjustment of ...	188	Latent Image and its Development ... ..	29
Exhibitions and Exhibitors. By W. D. Welford ...	618	Half-tone Work, Apparatus for ... ..	252	Latent Image and the Nascent Silver Theory. By Dr. R. Abegg ...	196
Exhibitions, Autumn ... ..	394	Haloid Silver Compounds ... ..	270	Lazy-tongs Shutter. By J. V. Robinson ...	725
Exhibition Statistics... ..	648	Haloids, Separation of ... ..	644	Lead Plaster ... ..	768
Exhibitions, Technical and Otherwise ... ..	329	Hand-camera Lens Adjustment ... ..	486	Lens, A New ... ..	38
Exposure and Development ... ..	30, 302	Hand Cameras ... ..	126	Lens, Elementary Principles and Practical Uses of ...	809
Exposure and Lighting ... ..	253	Hand Grenades and Cinematography ... ..	303	Lens Testing ... ..	165
Exposure of the Back of the Plate ... ..	39	Hastings Exhibition ... ..	137	Lenses, Defining Powers of ... ..	51
Exposure, Theory and Practice of ... ..	442	Haze, and the Use of Light Filters in Landscape Work. By G. T. Harris ...	6	Lenses for Large Direct Portraiture ... ..	514
Extracting and Enlarging Single Figures from Group Negatives. By T. N. Armstrong ... ..	602	Heliochromy, Researches of E. Becquerel in. By P. E. B. Jourdain ...	292, 309	Lenses, Meaning of the Phrase "Equivalent" applied to. By Prof. J. E. A. Stegall ...	216
<b>F</b> ABRICS for Photographs ... ..	570	High Voltage Sparks through Air, Photographs of ...	115	Lenses, Notes on ... ..	126
Fat in Gelatine ... ..	261	Hill's Reflecting Camera ... ..	24	Lenses, Old and New ... ..	168
Ferric Oxalate for the Platinum Process ... ..	758	Holidays and Hand Cameras. By J. Pike ... ..	393	Lenses, On Sets of. By "R." ... ..	389
Ferrogallic Copying Paper ... ..	133	Home Portraiture ... ..	161	Lenses, Recent Improvements in... ..	265
Ferro-prussiate Process, Improved ... ..	790	Hot-weather Photography ... ..	575	Lifting Dishes ... ..	380
Ferrous-oxalate Developer ... ..	758	Hydramine: A New Developer ... ..	315	Light ... ..	111
Ferrous Sulphate ... ..	403	Hydrogen, Igniting a Jet of ... ..	628	Light, Analogies of ... ..	201
Film-flattener ... ..	375	Hydrogen Peroxide as the Active Agent in Producing Pictures on a Photographic Plate in the Dark. By Dr. W. J. Russell ...	185, 200, 211	Light and Colour ... ..	420
Film-holder, Henderson's ... ..	379	Hydrogen Peroxide, Use of in Photography ... ..	308	Light and Sight, Curiosities of ... ..	579
Film Photography ... ..	791	Hydrogen, Solid ... ..	596	Light and Toning Salts ... ..	676
Film Photography, Future of ... ..	643, 686	Hydroquinone and Iodine ... ..	535	Light Filters ... ..	95
Film Photography, New System of ... ..	134	"Hydroquinone B.R." ... ..	651	Light, New Action of ... ..	770
Films, Advantages of. By A. H. Baird ... ..	314	<b>I</b> LFD MANUAL ... ..	683	Light, Reflection of ... ..	677
Film Troubles... ..	162, 211	Illegitimate in Photography. By J. S. Schneider ...	568	Lighting ... ..	270, 643
Fish Glue, to Preserve ... ..	631	Illumination of the Dark Room. By W. E. Debenham ...	423	Lighting, By T. N. Armstrong ... ..	632, 810
Fixing Agent, a New ... ..	406	Illusion and its Cause ... ..	40, 84	Lighting, Photography of, in Daylight ... ..	125
Fixing Baths, Decomposition of ... ..	104	Imperial Dry Plate Works ... ..	395	Lightning Flashes, Photographs of ... ..	531, 564
Flashlight Accidents ... ..	104, 320, 391	Imperial Special Slow Bromide Paper ... ..	42	Lippmann Process ... ..	133, 598, 821
Flashlight Photography ... ..	314	Important Problems that Require Investigation. By H. S. Starnes ...	342	Lippmann's Process, Further Experience with ...	39
Flash Powders ... ..	313, 420	Incandescent Gas Mantles, Constitution of ... ..	84	Lime, Solubility of ... ..	388
Floral Photography ... ..	552	Incandescent Lamp, New ... ..	196	Limes, Varying Qualities of ... ..	275
Floral Photography. By T. N. Armstrong ... ..	424, 487	Incanto Purifier ... ..	48	Liquid Air ... ..	516
Flower and Fruit Photography ... ..	361	Indiarubber ... ..	692	Liquid Hydrogen and Crookes' Tubes ... ..	374
Flower Photography ... ..	328	Insect Photography by Artificial Light... ..	248	Lithographic Process, A New ... ..	372
Flower Photography in a Garden ... ..	166	Intensification and Reduction ... ..	156	Live and Let Live. By Hector E. Murchison ...	214
Focal Length of a Compound Lens, Determination of. By J. F. T. ... ..	85	Introduction to Almanac of 2000. By J. Rees ...	9	Living Pictures ... ..	381
Focal Length of a Compound Lens, Simple Method of Determining. By T. R. Dallmeyer ... ..	116	Inventions, Evolution of ... ..	554	Local Exhibitions. By Hector Maclean ... ..	731
Focal Length of a Lens ... ..	142, 187, 190	Iodide Paper ... ..	502	Local Reduction of Density. By A. Seeley ... ..	69
Foci of Lenses Altered by Heat ... ..	468	Iron Printing. By Professor E. Valenta ... ..	470	Long-range Photography ... ..	447
Focussing by Scale ... ..	214	Iron Printing Processes. By Rev. F. O. Lambert 294, 312, 327, 345, 362		Lothian Stereoscope... ..	172
Focussing Device, New ... ..	793	Irrregular-grain Process Blocks. By W. Gamble ...	485	Low Temperature and Light Action ... ..	131
Focussing Centrally and by Scale... ..	131	Italian Exhibition ... ..	31	Luxev Lantern ... ..	780
Focussing, Teed's Method of ... ..	507	<b>J</b> OLY Process ... ..	380	"Lying About, Careless Like." By W. D. Welford .	646
Frames and Mounts ... ..	328	Jottings. By Cosmos 37, 101, 164, 468, 518, 533, 564, 596, 692, 772		<b>M</b> ACHINERY, Photographing ... ..	483
Frona Pneumatic Flap Shutter ... ..	188	Journalistic Photography. By J. Rees ... ..	279	MacKenzie Daylight Slide ... ..	650
Frona Pneumatic Release ... ..	139	Joys and Sorrows of Photography ... ..	13	Magnesium Apparatus, Levy-Lajeunesse ... ..	89
Frozen Pipes, Thawing ... ..	804	<b>K</b> ACHIN ... ..	510, 585	Magnesium Cartridges ... ..	153
Funerals, Photography at ... ..	244	Kachin. By E. W. Foxlee.. ... ..	373	Magnesium Flashlights ... ..	517
<b>G</b> AMBIER BOLTON Camera ... ..	251	"Kalko" Background Paint ... ..	107	Making Wood Fireproof ... ..	85
Gas Cylinders ... ..	820	Karamello ... ..	589	Manila, Photography in ... ..	506
Gelatine Emulsion, An Improved... ..	264	Keeping Qualities of Dry Plates ... ..	311	Marking Printing Papers ... ..	47
Gelatine, Estimation of ... ..	71	Kinematograph, Novel Use of ... ..	452	Markings on Negatives ... ..	574
Gelatino-chloride, Developing Partly Printed ...	598	Kissing by Cinematograph... ..	204	Massey Field and Studio Stand ... ..	202
Gelatino-chloride Paper ... ..	660	Kites, Use of ... ..	276	Mawson Competitions ... ..	747
Gelatino-chloride, Simultaneous Development and Fixation of ... ..	561	Kodak Film in Spectroscopic Photography ... ..	249	McKellen, Limited ... ..	42
Glass Diaphragms ... ..	270	Kodak Films, Transferring. By W. N. Jennings ...	540	Measuring Volumes ... ..	372
Glass for Orthochromatic Purposes. By J. R. Gotz .	557	Kodak, Limited ... ..	77	Melano-chromosome ... ..	822
Glass for Vacuum Tubes ... ..	676	Kodak versus Gamage ... ..	461	Mental and Moral Training in Photography. By D. Cobb ...	505

## EX CATHEDRA.

MR. BENNETTO, the *soi-disant* discoverer of the secret of colour photography, has been interviewed by a representative of the *Western Daily Mercury*, published at Plymouth. The interview supplies amusing reading of a kind with which Mr. Bennetto has made the photographic world only too familiar during the last two or three years. The *Mercury* reporter says: "Since Mr. Wallace Bennetto, of Newquay, obtained patents in connexion with colour photography, he has been criticised severely. But he has not abated his energy. A representative of the *Mercury*, who yesterday saw Mr. Bennetto, found him busy, and sanguine that in the near future he will be able to convince even his most bitter opponents that the secret of colour photography has been discovered. 'The statements made by the BRITISH JOURNAL OF PHOTOGRAPHY,' remarked Mr. Bennetto, 'misrepresented the whole thing. Had I cared to do so, I could have completely upset every one of the statements made by that JOURNAL; but I have decided to adopt another course. Very shortly, probably in January, I intend giving a lecture and demonstration here in Newquay with the object of making the process clear to the public.'"

OF course we have made no "misrepresentations" at all. We simply published the full text of Mr. Bennetto's description of his own process, and, if there are any misrepresentations in that, the fault obviously does not lie with us. Nor have we made any "statements" which Mr. Bennetto or anybody else could completely upset. But there are a considerable number of questions bearing on the theory and practice of Mr. Bennetto's patented *réchauffé* of three-colour photography that we put to him in our issue of November 18 last (pp. 737 and 738), which he has not yet attempted to answer. "He regretted he had not time to answer all our queries" (BRITISH JOURNAL OF PHOTOGRAPHY, December 2, 1898, p. 783). And this from the patient, plodding genius who could, an' he would, completely upset every one of our statements (*i.e.*, answer our questions)! Science is distinctly the poorer by Mr. Bennetto's refusal to grasp the opportunity we purposely gave him of convincing the world that he has a grip of the subject about which he has been talking and writing so long.

\* \* \*

FANCY making his process "clear to the public" at Newquay, where colour photography is put to the test blindfold! Does it not all read like an extract from a Gilbert and Sullivan comic opera? Then, after his "patented" camera and process have, in our columns, been pulverised so far as their novelty and practicability go, we are told that "with my patent camera any one will be able to take a photograph in colours as easily as he now takes an ordinary photograph. The camera takes the picture with one exposure, the plates are developed by one operation, and a worker can print as many pictures in a day in colours as he now prints of ordinary photographs. This is my camera. You see it is rather smaller than the ordinary camera. The use of a red transparent glass in that frame, fixed at an angle of 45°, and special plates on the top and at the back of the camera, give the results. The camera is as easy to use as an ordinary one." Mr. Bennetto's "patent" camera and "patent" process must make any intelligent student of our columns since November 18 laugh with pity. Neither the camera nor the process, as described, is worth a snap of the fingers, and cannot be seriously regarded as the production of a scientific student of the difficult problem of colour photography.

'COLOUR photography à la Benetto is fairly easy. He says: "You see the difficulties are not so great as some would have the public believe. Many people have been here, and I have never refused to show any one of my pictures. Most visitors come doubting the genuineness of my discovery, but all go away astonished at the excellence of the pictures, and satisfied that I have solved the problem of colour photography. Doubtless there will be improvements on what I have done—I hope to make further advances myself—but I claim that I have solved the problem." Mr. Benetto's visitors (!) are satisfied that he has solved the problem of colour photography; but who are his visitors, and what do they know of the subject? And he expects there will be improvements on "what he has done." Possibly; but for two and a half years we and others have been asking, What has Mr. Benetto done? Nobody, except Mr. Benetto, appears to know.

\* \* \*

A *Treatise on Photographic Optics*, by Mr. R. S. Cole, M.A., late Scholar of Emmanuel College, Cambridge, will be published early in January by Messrs. Sampson Low, Marston, & Co., illustrated with numerous diagrams. The object of this treatise is "to provide an account of the principles of Optics as far as they apply to Photography, in a form which is of scientific value, while not of too abstruse a nature to place it beyond the reach of all but the professional mathematician or physicist."

\* \* \*

THE recent accident at an electroplater's, in Clerkenwell, when an entire family nearly lost their lives, serves to remind one of the dangerous properties of cyanide of potassium. The accident, according to the reports, arose from the upsetting of an electroplating bath and, at the same time, a vessel of sulphuric acid. The former consists of a solution of the cyanide of silver in cyanide of potassium, and the mixture of the two—the acid and the bath—sets free cyanic acid, the vapour of which is highly poisonous. Cyanide of potassium is not now much used in photography, except by those who work the wet-collodion process, as in making negatives for the different mechanical processes, where it is the usual fixing agent. Some operators have worked with the cyanide for years without experiencing the slightest inconvenience therefrom, while with others the fumes from it have had serious effects, much in the same way that metol is found to behave with different workers; with some it is inert, with others just the reverse. The ill effects from the fumes of the cyanide of potassium can be greatly mitigated by a little care. As a rule, the negatives are fixed over the same sink they are developed over; consequently, when the solution is washed off, it mixes with the remains of the acid developer, when immediately cyanic acid is given off; hence the mischief, if any. If separate sinks were used, or baths employed for the fixing solution, the ill effects of the cyanide would be reduced to a minimum.

\* \* \*

THE total eclipse of the moon last week was very disappointing to would-be observers in this country, owing to the wretched state of the weather. At all our observatories full preparations were made for important observations, both visually and photographically, but nothing could be done. We know that several amateur photographers, too, had made arrangements to secure photographs of the event, and they, of course, were dis-

appointed. The clerk of the weather in Germany appears to have been more propitious than ours here, for we read that at Berlin the Emperor and Empress watched the eclipse from the Palace, and that three of the Princes did so from the Observatory; also that there and at the other observatories in the neighbourhood of Berlin many photographs of the phenomenon were secured. Hence those who require photographs of the moon's eclipse of 1898 will have to take those "made in Germany," or elsewhere, as none were obtained in this country.

\* \* \*

THE Swedish Expeditions sent in search of Andrée have now returned home after thoroughly exploring and making diligent inquiries in Northern Siberia, but without finding any traces of him or the balloon. The *Standard's* Stockholm correspondent, telegraphing one day last week, says that the journey, though unsuccessful in the accomplishment of its primary, but almost hopeless, object, has not been without results of scientific value. It will be remembered that, when Herr Andrée first brought his project forward, and explained it in this country a year or two before he started, many English scientists were very sceptical as to its success, and expressed themselves very positively on the subject. Up to the present, unfortunately, their prognostications seem to be verified. Still there may be a possibility that he is safe. We fear, however, that, if he does return, photography will not be much benefited, from what it was surmised could be accomplished, as it is scarcely probable that any result will have been secured of any value after so long a lapse of time and the vicissitudes the gelatino-bromide films will have undergone.

\* \* \*

A FORTNIGHT ago we referred to the discovery of a factory in Belgium where fictitious works of the best masters had been produced in almost wholesale quantity, and that the principal market for these spurious pictures was America, where, it is alleged, they are to be found in some of the principal private collections. When alluding to this matter, we mentioned that American millionaires were always ready to pay large sums for European pictures, particularly for those of the most renowned of the old masters, not for national galleries, but for their own private collections. We now learn that Van Dyck's picture of the *Madonna*, which formerly hung on the walls of Blenheim Palace, has found its way to the United States. It is further intimated that its future resting place will probably be in a private collection at Baltimore. Our National collections are not yet so rich that we can afford that the best works of the old masters should be allowed to leave the country. However, the funds granted to the Trustees of our National Gallery are not sufficient to prevent it. More, perhaps, is the pity, so far as art is concerned.

\* \* \*

THE Court of Appeal of Paris has just pronounced judgment in an action brought by the Directors of the Porte St. Martin Theatre to restrain the editor of the *Photo Programme* from producing scenes from "Cyrano de Bergerac." The Tribunal of Commerce held that, the play being a public spectacle, its scenes might be photographed and reproduced by a third party without permission; but this judgment has been reversed by the Court of Appeal, which has decided that the scenery of a play is among the *œuvres de l'esprit* protected by the law of 1793. The *Photo Programme* is therefore forbidden to sell its illustrated programmes under a penalty of twenty francs per copy.

## HINTS FOR THE AVOIDANCE OF WINTER TROUBLES.

It will be fresh in the memory of most—the severe winter of some three years ago, when we had several weeks of hard frost, commencing in January and lasting well into March, and the inconvenience it caused to the majority of professional photographers in the form of frozen water supply, burst pipes, damaged property therefrom, and damp walls for, perhaps, months. Not a few of those who suffered those inconveniences saw how easily they might have been avoided had a few simple precautions been taken beforehand. Most of those who suffered then came to the firm determination that on the advent of the following winter they would be prepared for severe weather, whether it came or not. It would, however, be interesting to know how many adhered to their determination. Since the memorable winter of 1895 we have had no real “old-fashioned winter,” or anything that needed special timely care; but, with this fickle climate of ours, we do not know how soon we may again be involved in an arctic temperature, or how long it may last if we are. Are we prepared for it?

Curiously enough, but a week or so before the memorable frost alluded to set in, we sounded a note of warning as to what might happen, and the precautions that should be taken to avert trouble before it came, which, had they been acted upon, would have saved serious inconvenience to many. Hence our present reminder.

As to precautions, the first and foremost thing is the water supply, for without water little business can be carried on by professional photographers. In some instances the service pipe from the street to the premises is laid far too near the surface to resist, unless further protected, a continued hard frost such as that of 1895. With the service tap, though it may be deeply laid, the little shaft by which it is reached is often only protected by a loose wooden cover. This should receive first attention by being packed full of hay or straw, or, better still, with sawdust. Then there will be little danger of the frost reaching the tap. If the pipe from that to the building is near the surface of the ground, it should be further protected with more mould laid on and well trodden down. A still better plan is to cover it up with a foot or so of stable manure; its unsightly appearance, though rarely noticed in frosty weather, may be hidden by a few loose boards. This precaution need not really be taken until there are some indications of the approach of severe weather.

Any exposed pipes outside the building should at once be made safe, as only a few hours' hard frost is oftentimes sufficient, if the water is stagnant in them, to freeze them, and when once the water has congealed the trouble has commenced and will extend. Several thicknesses of old felt carpet or strands of haybands wound round them is a perfect protection. A special material for the purpose, “hair felt,” is now sold at most hardware shops, which answers admirably.

With regard to the pipes within the building from the cistern to the workrooms, there is little fear of their freezing during the daytime, when the water is in pretty general use; it is at night, or between the Saturday and Monday, that the trouble is most likely to occur. This may, however, usually be avoided by leaving the different taps continually dribbling, so that the water is in continual motion in the pipes; but that, of course, means waste of water, either at the cost of the consumer or the water company. The better plan, however, is to completely empty the pipes every night, so that there is nothing left in them to freeze. The simplest way of doing

this is to have a stop cock fitted immediately under the cistern, and, just below that, a small air cock, such as is fitted on hot-water pipes. Then, when the water is shut off at the cistern and the air cock opened, and all the lower taps are opened, the water will drain completely out of the pipes. The object of the air cock is to act as a vent, admitting air, otherwise the water could not escape from the pipes. A simple extemporary arrangement that answers the same end, though less convenient, is to plug the pipe from the tank with a piece of tubing—iron “gas barrel” for example—of sufficient length to reach above the top of the water. Then, if all the taps be opened, the pipes will be emptied, and air will be admitted to them through the plugging tube. With the above precautions there need be little fear of inconvenience with the water supply, even with a good spell of wintry weather.

If perchance, through want of care, the pipes get frozen, there is a very probable chance that some of them have burst. Now, there used to be the idea and it still prevails with many of the public—and some plumbers, notwithstanding what the Plumbers' Company have done for the craft—that the pipes burst with the thaw. Of course, that is a fallacy; they burst with the expansion of the water when it freezes, and the fracture only becomes manifest, unless sought for, with the thaw. When any of the pipes are found frozen, they should at once be carefully examined throughout their length, and the fracture, if there is one, will be seen by the bulged metal and protruding ice. Then the plumber should be immediately sent for to do the needful, and thus save a flooding; also, while the frost lasts, plumbers are usually at a discount, while after a general thaw they are usually at a premium, and often a high one too. If a thaw sets in before the burst is detected, the best way of dealing with it, if the supply cannot be quickly shut off, is to, with a hammer, batter up the pipe itself a few inches from the rupture and thus effectually close it. This treatment will add a little to the plumber's bill, but it will be more than compensated for in the mitigated damage to property, and possibly wet walls for weeks. When the premises are heated by hot-water pipes, special care of them is necessary in severe weather, for if anything goes wrong, there is no other means of heating. The fires should never be allowed to go out, night or day, for, if the pipes freeze, some of them are almost certain to have split, or the joints ruptured. A very small fire is, however, sufficient to keep the water in circulation and thus avoid the freezing. Should, however, from neglect, the pipes have become frozen, the fire should not be started before they are thawed by some means or other, as it might cause an explosion of the boiler. The supply pipe to the boiler, which really acts as a safety valve, should be specially looked after, for any blocking of that might lead to equally as disastrous a result as that just alluded to. It is well at this season to keep the old proverb in mind, “A stitch in time,” &c.

---

**A New Mode of Making X-ray or other Vacuum Tubes.**—Professor Dewar, at a recent meeting of the Royal Society, showed a beautiful experiment, the final result of which was the production of an almost perfect vacuum tube. The end of a closed tube containing air was rapidly dipped into liquefied hydrogen, and the contents of the tube quickly condensed in the state of solid air. That part of the tube from which the air had been so removed was sealed by heat and separated from the rest. It was then found to possess an extremely high vacuum, so high, indeed, that an electric current could scarcely be passed through it.

The rapidity of the operation was extraordinary, one minute's immersion being enough to bring down all the air and produce the vacuum.

**A Non-inflammable Celluloid.**—M. Béthisy has obtained a French patent for the manufacture of a celluloid that is non-inflammable. The process of manufacture is the same as usual, so far as the manufacture of the nitro-cellulose, but ten to fifteen per cent. of dried egg or blood albumen is added, and ten to fifteen per cent. of powdered mica to obtain the transparent kind, and ten to fifteen per cent. of alum and asbestos in powder for the opaque kind. It is further incorporated with vaseline oil dissolved in acetic ether, and then solution of chloride of zinc and white gelatine is added, and the mass allowed to stand for some hours and then pressed into blocks.

**Purification of Acetylene.**—Dr. A. Frank has recently obtained a German patent for the process of purifying acetylene by passing it through a solution of cuprous chloride acidulated with hypochloric acid. Experiments have shown that with a litre of the liquid fourteen cubic centimetres of acetylene, which was obtained from calcium carbide of bad quality, could be completely purified. The purifier may also be used in the solid form. It removes from the gas all prejudicial and ill-smelling impurities without in any way affecting the acetylene itself. The purifier can be, after use, at once purified by simply boiling. The cost is, therefore, very low, about half a pfennig for a kilogramme of carbide. The purified gas does not develop smoke when burning, and has a pleasant smell of aldehyde. The burners are, moreover, not attacked or clogged up, and the purifier is not, even after continued use, in any way dangerous, and will not contain any explosive compound. Other metallic salts may be used, but their action is not so intense nor so economical.

**Aluminium for Scientific Instruments.**—It needs only a glance at an optician's shop to see how great a hold this metal has taken of the makers of opera glasses, telescopes, photographic lenses, &c.; but, when we come to look round at the workers with these and other such instruments, we do not see them in common use. The reason is simple, the high price of most instruments where aluminium replaces brass. Whether that excessive price will ever be done away with is an interesting and fruitful subject for conjecture. Every year almost sees a reduction in the price of the raw material of the metal itself. That made by the agency of the Foyer's Falls, we read, is now priced at one-and-three-pence per pound, which for equal bulk is cheaper than either copper, brass, or tin. The metal as first produced is not pure enough, and is sent to Milton, in Staffordshire, where it is brought to a refined state of purity. Seeing that the Milton works are built to enable four tons a day to be turned out, there is evidently a demand *in esse* or *in futuro* somewhere.

We notice that quite recently a microscope constructed entirely of aluminium, except the wearing parts, was exhibited at the Quekett Microscopic Club. Its lightness was admired, but that was looked upon as about the only gain against increased cost. So far there is no doubt that aluminium is difficult to work, difficult to solder, difficult to cut for screws; but we see no reason why an efficient alloy should not be invented which would nullify all these disadvantages. Meanwhile, at a price of one penny per ounce, we feel that it ought to be largely available for photographic purposes.

**The Royal Academy.**—The Royal Academy Winter Exhibition is now open. This year it is limited entirely to the works of Rembrandt. This old master's work, it is well known, was more entirely confined to figure studies than to anything else, lighting and grouping being very important features. This fact makes this year's show of special interest to photographers, at least to those who make that phase of photography their study. The Exhibition

at Burlington House includes the greater portion of the pictures shown at the Rembrandt show last year, at Amsterdam, with some additions, amongst which are some lent from the Queen's private collection, that were not shown in the Dutch Exhibition. In all there are over a hundred works on view, in addition to a collection of pen-and-wash drawings. As just intimated, photographers will do well to see and study the pictures now on view, for it must be confessed that many have still much to learn in the matter of lighting and posing, as well as in the grouping of figures—that is, if one may judge from the photographs shown in recent exhibitions of the Royal and the Salon, where, when strong contrasts in lighting have been attempted, they were exemplified by crude lights and deep shadows, without a trace of detail. Such was not Rembrandt's style. For years past portraitists have produced "Rembrandt" photographs; if the majority of them were to visit Burlington House and see the great master's works—and such a collection may never be on view again—they will see that most of their productions have been mere parodies on Rembrandt.

**How to Make Sure of Seeing the Great Meteor Storm.**—In view of the almost certain occurrence of the great meteor shower next November, and the possibility of observers' hopes being frustrated by bad weather, we read that at various places balloons are to be constructed that will be capable of conveying the astronomer beyond risk of cloud contingencies. Already three stations have been selected—in Europe, in America, and in Central Siberia respectively. At first the arrangements will be purely experimental, and will be managed by M. Janssen.

#### BY THE WAY.

How true it is that "the best-laid schemes of men and mice gang aft agley!" The technical side of photography has always had at least as much attraction for me as the merely pictorial. I have taken pleasure at various periods in preparing my own plates, making my own emulsion and collodion, even in albumenising my own paper and coating my own carbon tissue, and, if the outcome of my efforts were not absolutely up to the standard of the regular commercial article, at least the pictorial results obtained therewith gave me infinitely more satisfaction. But those results have always been confined, or nearly always, to picture-making within the bounds of my limited capacity, and the higher branches of the science have troubled me very little. It was rather as a change, then, and partly out of curiosity, that I availed myself of an opportunity the other evening of assisting in the photographing of the lunar eclipse.

I dare say a good many more besides my friend and myself had formed somewhat similar plans for that same evening, but there is where the "men and mice," &c. proverb comes in; or, as our friends across the Channel have it, "l'homme propose, mais Dieu dispose." I attended a "full-dress rehearsal" on Boxing night, and everything went as smoothly—to use the chief operator's simile—"as half a pound of butter on a hot plate." Man's portion of the arrangements had been adjusted to a nicety, and those beyond his control were simply perfect, and no one could have wished for greater success than attended the production of a trial series of pictures of the moon taken at regular intervals. Wednesday night, again, was another perfect one for the purpose, and why the eclipse should be sandwiched in between two such opportunities is difficult to conjecture, for all that it was possible to see at intervals was a hazy vision of the moon obscured by scudding clouds of varying density passing at hurricane velocity in an easterly direction. Knowing that such a performance had been set down for that particular evening, there was just sufficient evidence to lead one to believe that the principal actors were fulfilling their parts; but, in the absence of any previous knowledge, I doubt whether the fact would have suggested itself to any one. In short, the total lunar eclipse of December 27, 1898, was a dismal failure and disappointment.

But it reminded me of a similar occasion—though it was only a *partial* eclipse, if I remember rightly—some thirty odd years ago, and set me thinking of the difference between “then” and “now.” I happened to be spending the evening with an old friend, who was not only an amateur photographer, but also an amateur astronomer of a most enthusiastic kind, and many a cold, frosty night have I wished his huge telescope at Jericho or the bottom of the sea, as with half a dozen overcoats and mufflers on, but with *bare hands*, I manipulated the adjusting screws of the speculum, and did my best to follow his orders, “turn right,” “turn left,” or “turn bottom,” shouted from the top of a ladder, where he performed some mysterious ceremony with a lantern at the open end of the tube, and didn’t seem to think it a bit cold. Of course, when ten o’clock or so came, we had to turn out to see how the eclipse was getting on or “promising.” On that particular occasion I did not mind, as I had never seen an eclipse through a real “astronomical” telescope, so I joined in with perfect willingness in getting things ready. Like many other mundane pleasures, the reality fell far short of the expectation; in fact, I liked it better without the telescope.

However, when we had had enough of it, we returned indoors and discussed it from a photographic point of view, my friend waxing eloquent on the subject of photography as a possible aid in astronomical research, if only plates and lenses were more rapid. Of course, long previous to the period I refer to, photography had been utilised by astronomers, but only in portraying our two principal luminaries, and then only with the aid of the appliances of a well-equipped observatory; but my friend’s dream was to so far curtail the exposure that no transit instrument, no machinery of any kind, should be needed, but that an amateur like himself should be able, by practically instantaneous exposure, to secure permanent records of the heavenly bodies, that he could study at his leisure. This aspiration, so far at least as the rendering of anything but outline is concerned, has not yet been realised, even with regard to the sun and moon, but another dream, to which he attached even greater importance and looked upon as even more difficult of attainment, has been more than fulfilled. That was the securing, by means of photography, accurate maps of the heavens, with all the stars of any importance in their correct positions; and, impossible as it seemed to him at that time, he lived long enough to be familiar with not only the achievements of Dr. Roberts, the Brothers Henry, and others in that particular direction, but also of Dr. Huggins, Janssen, and others in the apparently still more difficult branch of spectroscopic work.

So far as the simple rendering of an eclipse is concerned, or even a star transit, his idea of bringing such work within the reach of the amateur has been realised, and it is now some years since the first successful attempts were made in this direction; but it was not until the other evening that I realised how comparatively easy it really is to one who lays himself out intelligently to do it. The instruments used by my friend on that occasion were simply his ordinary landscape camera and lens, the latter an anastigmat of about ten inches’ focus, I think. An arrangement had been previously made by which the camera could be set in such a position that the moon’s track crossed the centre of the plate, and “off and on” exposures made at intervals of, I think, ten minutes, gave a series of distinct images of the moon on different parts of the plate. Of course the images were small, but sufficiently sharp with the lens used to bear enlarging a good many diameters without losing what definition would be necessary to show the different phases of the eclipse. Equally, of course, the image would only represent the unobscured portion of the moon’s disc at each phase; but to the lay mind that is about all that constitutes an eclipse.

How much the optician, and how much the chemist, respectively, has contributed to this latter-day result it is not easy in a moment to calculate, but they have both done their share since that evening, thirty years ago, when my departed friend “dreamed dreams.” I remember about the same time, in some editorial remarks in this JOURNAL on the subject of instantaneous photography, it was suggested that the onus of further progress in that particular

direction rested with the optician rather than with the chemist. At that period wet plates had apparently reached finality so far as sensitiveness was concerned, for they had made no advance for some years; dry plates were hopelessly behind wet, and there was no prospect of any new departure, so the onus was thrown upon the optician to supply us with quicker lenses. The inadvisability of prophesying unless you are “in the know” is proverbial, for, although the wet plate remains much in the same position, as regards rapidity at least, as in the mid-sixties, the “chemist” has come manfully “up to the scratch” by making the dry many, probably hundreds of, times as quick as anything existing at that time.

But the optician has been far from idle, and for such work as star-mapping, at any rate, his labours in shortening exposure have been little less important than those of the chemist. I do not remember whether the reference to the optician’s duty which I have quoted was made before or after the advent of lenses of the rapid rectilinear type; but, so far as concerns the kind of work I have just mentioned, it makes little difference. But, for general purposes, compare the lenses of the early sixties with those of to-day. The veriest tyro nowadays must have a “rapid rectilinear” with his “complete set” if he can afford it, and looks with scorn upon the humble “landscape lens;” the more advanced man treats the “R. R.” with almost equal contumely, though in its day, and even now for many purposes, its performance is not to be despised; and on its first introduction it was in reality a “new power” in the hands of the landscape photographer.

Previous to that the best lenses, doublet and triplet lenses, mind you, not to be despised at the present day for performance, were slow according to modern notions, but I will venture to say that at least nine-tenths of the work done—and all the best early work—was done with the despised single lens. Roger Fenton’s Crimean series, Frith’s 24 × 18 Egyptian and Holy Land views, G. W. Wilson’s and Francis Bedford’s landscapes, and Mrs. Cameron’s portraits, to say nothing of a very large proportion of the best amateur work, all came from single lenses; and, let it be said, much of that work would hold its own in any company to-day on all points but rapidity. But the single lens of that day, it must be admitted, was a slightly different article from that of the same type prevailing now. It was, in fact, the almost universally employed instrument, and the optician devoted to its construction as much care and trouble as he does now to the most expensive anastigmat, and, as a consequence, instead of getting a quarter-plate single lens for half-a-crown or three shillings and sixpence, as I have seen them advertised, you had to pay a decent price for them. The 4½-inch focus lenses of Ross and Dallmeyer ran from twenty-eight shillings to forty shillings a piece according to the style of mount. I have in my possession at the present time, and have had it as long as I can remember, a lens by Lerebours and Secretan, and “signed” by the latter, that I would not exchange for half the rapid rectilinears of the same focal length (six inches) that are “going” nowadays. In fact, for pure landscape, it will do what nine out of ten of them will not, and do it better than most of them, namely, cover a half-plate to the corners. I have used it, with a small stop, as a wide angle on 7½ × 5, but that was rather a strain. Its full aperture is equal to  $f\cdot5\cdot65$ , or half the rapidity of a portrait lens, and with that opening it makes a much sharper portrait than many I have seen exhibited.

Carey Lea, in his *Manual of Photography*, published nearly thirty years ago, or perhaps quite thirty, lays it down that, for copying line engravings, the “stop must not exceed  $f\cdot60$ , or one sixtieth of the focal length.” Probably, so far as the very best of existing lenses at that time were concerned, he was quite right; but what would he say of modern anastigmats, which will give an absolutely better result working at, say,  $f\cdot7$ ? This alone means a gain in rapidity, solely due to the optician, of about seventy-five times.

But I have more than filled my allotted space, so I will conclude by wondering whether in another thirty years we—or those of us who may be left—shall have gone back to single lenses made from achromatic glass, and absolutely free from aberrations of every kind.

DOGBERRY.

## HAZE, AND THE USE OF LIGHT-FILTERS IN LANDSCAPE WORK.

"AERIAL surf upon the shores of earth," is Thoreau's refined and poetic description of a condition of the atmosphere well known to landscape photographers, and, perhaps it is safe to add, well dreaded also; for on the days of this haze the topographical photographer who has any distances to contend with may, if he be a user of undyed plates, conscientiously make holiday, his labour, under such conditions, being about as profitable as were the labours of the classical Sisyphus. But there are degrees in haze, as in so many other things; and the experienced landscape worker knows many degrees between the light heat haze that just flims over the distant mountains, scarce blotting out their details, and the uncompromising haze that invariably rolls in with an easterly or north-easterly wind, and which effectually stops photography where any distance is comprised. The mean of these two extremes is the debatable land of photographic possibility. On such a day the undyed plate is absolutely useless, and photography with dyed plates is only possible when deep yellow, verging on orange, filters are used. Let it be borne in mind that topographical photography only is held in view in thus taking up the cudgels for deep light-filters in landscape work; artistic photography, whatever that may be, and studies of "effects" are emancipated from the trammels that hedge round mere topography.

My own outfit consists of three light filters, increasing the exposure in geometrical progression, thus:—

2, 4, 8.

No. 2 is a very slightly tinted screen, with which drop-shutter exposures can be made if necessary. No. 4 is the most useful generally; it filters out more of the blue, and, when a fair amount of haze is present in the atmosphere, it preserves the distance in a way no ordinary, or orthochromatic, plate without a screen possibly could. No. 8 is a *derrière resort*, and priceless in its usefulness. Much has been written against the use of deep filters in field work, and it is obvious that one would only resort to them under circumstances of exceptional difficulty; but, where such occur, the deep screen, and that only, is the one possible solution. Many times during the summer of 1897, so phenomenal for its haze, the deep filter enabled me to obtain subjects that would either have remained untaken or have necessitated days of tedious waiting for clear weather. Over-correction is inevitable when using such deep screens, but in very many subjects it does not make itself felt to any great extent; and in mountain districts, where such a filter reaches its greatest usefulness, the disadvantage of over-correction is at its minimum.

Much of the evil ascribed to the use of deep filters arises from under-exposure. Using the No. 8 screen above mentioned, it will be found that where subjects have bold foregrounds, broadly lit, it is quite safe to add fifty per cent. to the light resisting value of the filter, over-exposure rarely or never resulting. Only when the subject is open and devoid of shadow masses is it desirable to keep near the exact multiplying power of the filter. When working on the coast, the erroneous correction given by the deep filter to the water is really a serious drawback to its use, and necessitates the negative being doctored before printing, otherwise the low tone of the sea in the print becomes painfully offensive. This can be obviated by covering the water in the finished negative with a single thickness of papier minéral, which gives in the print a close approximation to the correct tone. The defect just mentioned is not the only one accompanying the use of this especial filter; when it is most required, i.e., when the haze is too dense for filters of medium depth, there is usually almost an entire absence of clouds, and the blue of the sky, already degraded by the haze, is removed to such an extent by the screen that in the print the sky is represented as a uniform deep tint. This necessitates lightening the sky portion of the negative with tracing paper, or adopting the more heroic measure of completely blocking it out with black varnish and printing in a sky from a second negative, which, where possible, is the most satisfactory course. It may be said that these defects in the deep filter are quite sufficient to condemn *in toto* its being used out of doors, but the fact remains that with judicious after-treatment of the negative its use enables the topographical photographer to get work done that otherwise would have been impossible.

When the photographer is compelled to work in dull weather, with overcast sky, the use of yellow filters aids enormously in getting results superior to those obtainable with ordinary plates. The greens are brightened up, and the distance rendered clearer to such an extent that a landscape photographed with a deep filter under a dull, heavy atmosphere will often have the appearance of having been taken in a good diffused light. This fact alone should make the use of orthochromatic plates and light-filters commendable to the professional photographer, who, indeed,

seems the most persistent in ignoring their aid. Another direction in which filters, and notably deep ones, become extremely valuable in the work of the professional photographer, is in photographing buildings in large towns, where smoke, haze, and congested thoroughfares make it almost impossible to obtain good results when working in the ordinary manner. The shadows are covered with grey haze, and the exposure has not been quick enough to avoid movement in the traffic, nor sufficiently prolonged to obliterate it altogether. But, use an orthochromatic plate and a deep enough filter to clear away the haze, the long exposure necessary under these conditions quite obliterates the effects of the traffic, and the result is a photograph with clear shadows and an absence of blurred figures in the foreground.

The most convenient place for the filters is behind the lens inside the camera. For landscape work my lens outfit consists of a casket set ranging in foci from three inches to three feet; the mounts of the various lenses are of one diameter, and the three light-filters are mounted in flanges that slip over the mount of the posterior lens inside the camera. It is therefore the simplest matter possible to affix either one of the screens in position just before inserting the dark slide. With filters, 2 and 4, the focus of the lens remains undisturbed, but, when using the deep 8, it is necessary to finally focus the image after the screen has been placed in position.

There is little doubt but what the average photographer has seriously misunderstood the orthochromatic plate, especially when applied to landscape work. He has probably tried them in the field against the ordinary plate, and upon the first subject that came to hand, the difference has been inappreciable, and he has consequently rejected their use. It has never occurred to him that the real value of them to the landscape worker lies in their sensitiveness to the yellow filter, whereby he is enabled to eliminate the haze that mars his distance. When I recall the days of tiresome waiting for absolutely clear weather that, in my own experience, these friendly filters have obviated, my feeling is one of gratitude to orthochromatic photography, and in reflecting on the apathy, almost amounting to antipathy, shown by the average photographer to their use, I cannot help quoting "There is no darkness like ignorance."

GEORGE T. HARRIS.

## METHYLATED SPIRITS.

There is hardly a substance used in connexion with photography in the United Kingdom about which so much misunderstanding exists among amateur and professional photographers as the article called methylated spirits. I therefore propose to correct this misunderstanding from a reliable source, so that in future your readers may know how and where to obtain this very useful and, in many cases, indispensable article.

Methylated spirit is the outcome of a demand made in 1855 by the manufacturers of the United Kingdom for liberty to be allowed to use duty-free alcohol or spirits of wine in the arts and manufactures to enable them to compete on equal terms with the foreign manufacturer who enjoyed that privilege in his own country. After an exhaustive inquiry and series of experiments by Mr. George Phillips, founder of the Inland Revenue laboratory, out of which has grown the present Government laboratory presided over by Dr. Thorpe, it was found that, if about ten per cent. of wood naphtha were added to spirits of wine, the mixture, while retaining all its properties useful to the manufacturer, becomes so nauseous to the taste as to be absolutely unfit it for use as a beverage, and consequently its use duty-free in the arts and manufactures, under reasonable restrictions, would be unattended by any danger to the revenue derived from spirits. These conclusions were subsequently verified by a committee of distinguished chemists, and legal sanction was without delay given to the proposal, resulting in immense benefits to the home manufacturers.

The mixture is now made under the superintendence of the Excise authorities by distillers, rectifiers, and licensed makers. The spirits used are technically called plain British or unsweetened foreign spirits, not less than fifty per cent. overproof, or rum not less than twenty per cent. overproof, and they are mixed with one ninth of their bulk of wood spirit or naphtha not less than sixty per cent. overproof and previously approved by the Commissioners of Inland Revenue. This is now commonly known as "ordinary" or the old quality of methylated spirits, and is the only description fit for use in photography. It can only be obtained from the makers in quantities not less than five gallons at one time by persons who have received the requisite authority from the Commissioners of Inland Revenue, who generally grant such authority to all *bona-fide* applicants.

Some few years ago, in order to counteract a tendency among certain

classes of the people to use methylated spirits as a beverage and substitute for duty-paid spirits, and as the methylated spirit so used was obtained from the licensed retailers of such spirits, such as oilmen, grocers, chemists and druggists, it was found necessary, for the protection of the revenue, to further contaminate or denature the spirit by the addition of three eighths of one per cent of crude mineral naphtha, supplied for sale by retail, in quantities not exceeding one gallon at a time by retailers. This mixture becomes cloudy on dilution with water, it is the only quality which can be purchased from retailers, and, owing to the presence of mineral naphtha, is quite unfit for photographic purposes.

Another variety, often sold to inexperienced amateurs and professionals by oilmen, chemists, and others, as methylated spirits, is technically known as "finish" and contains in solution at least three ounces per gallon of gum resin. Needless to say this article is unfit for use in photography. I will now summarise the foregoing. There are three mixtures of duty-free spirits allowed to be used in the arts and manufactures:—

(1) Ordinary methylated spirits, to be obtained only on the authority of the Commissioners of Inland Revenue from authorised makers in quantities not less than five gallons at a time. Authority to use the spirit may be obtained on application through nearest supervisor or officer of Inland Revenue. The application, if *bona fide*, is rarely refused, but the Commissioners may require bond for the proper use of the spirit. This is not, however, insisted on when the quantity used in a year does not exceed fifty gallons and a still is not kept. On receipt of the necessary authority, the local supervisor will furnish the user with a "Requisition Book" and, on forwarding one of the forms of requisition properly filled up, with his order to the maker, the quantity of spirit requisitioned will be supplied accompanied by a permit, which must be preserved and handed to the supervisor or officer of Inland Revenue, who is obliged to visit the premises occasionally to see that no improper use is made of the spirits.

(2) Mineralised methylated spirits. As stated, this is specially prepared for sale by retail, and is the only description of methylated spirits which can be obtained, except as in (No. 1). It is, as previously stated, quite unfit for photographic purposes.

(3) Finish, is in fact a kind of polish, about which enough has been already stated. While on this subject, it may be well to point out that users of methylated spirits subject themselves not alone to the loss of the privilege of using the spirit, but also to extremely heavy penalties for purifying the spirit in any manner whatever, whether by "dehydration," "treatment with caustic potash" "filtering from quicklime," or "distilling off in the usual way," as I have recently seen, no doubt erroneously, recommended by an important firm in a useful little monthly.

THOMAS LOWRY.

## PHOTO-CERAMICS.

[Translated from the *Deutsche Photographen Zeitung*.]

It is a remarkable sign of the times that at the present moment, when photography is prostrate as an industry, there should be so much long-winded, gushing talk concerning its artistic character. I do not think this will help the small photographer in the least, and it is far more useful to give him practical advice, showing how he may add to his income with the apparatus and appliances he possesses.

This is not so easy as it may appear, as many branches, such as enlarging, architecture, landscape, &c., no longer come within our scope. Something new and original must be offered to the public, and, from our point of view, this is possible by turning one's attention to the production of photographic enamels.

It will be objected that the process involves technical skill that the ordinary photographer does not possess, as it is necessary that he should combine with the knowledge of his own profession that of the enameller in order to produce photo-ceramics.

This objection is not altogether groundless, but it is not so important as it may at first sight appear. We start by learning a variety of things, but it then appears desirable to specialise by division of labour, which may be seen in England at the present time. But many imagine that photo-ceramics are surrounded with great difficulties, even in the purely photographic part of the work, which is not the case. It is my object to offer some explanation of these and some other difficulties, and I hope the reader will give them a favourable reception.

By photo-ceramics we understand the preparation of burnt-in pictures upon porcelain or enamel plates with the assistance of photography. As these pictures have to be burnt in upon the material selected, it is apparent that their preparation must differ somewhat from the photo-

graphic processes ordinarily used. The usual silver image, toned or untoned, consists of so minute a quantity of metal that it offers insufficient resistance to the process of firing. The heat attacks the image so strongly that none but unsatisfactory results can be obtained. It is therefore preferred to produce the picture in material that will remain unaffected in the furnace, and which will give a pleasing and intense colour. These substances are metallic oxides, which, with a vitreous cement, the so-called flux, answer the purpose admirably, and are called enamel colours. The enamel colours, however, are not sensitive to light, and cannot be used for a direct printing process, nor for development, as bromide and chloride of silver may be, but they must be utilised by an indirect process. As the enamel colours are to be had in very fine powder, they are very suitable for the so-called powder process, which depends upon the properties of a bichromated gum or similar film. When such a film is exposed under a negative, those parts upon which light has acted lose wholly, or partially, their adhesive property. If a coloured powder is then dusted upon the film, those portions which have been wholly or partly protected from light hold the colour, and an exact negative picture is produced. By using a positive for making the print we obtain a positive image, and, if an enamel powder is dusted on, an image is produced which may be burnt into porcelain. This simple and certain method, known as the powder process, is therefore largely used for photo-ceramics.

If perfectly flat plates are used, the sensitive film may be coated directly upon the support, but a temporary glass plate may be used for the film, and, after printing and development, the picture may be transferred to the material upon which the picture is to be fired.

There are a large number of formulæ for preparing the sensitive film, but the following is distinguished by simplicity and novelty:—

### SOLUTION 1.

Fish glue .....	30 c.c.
Glucose .....	120 "
Glycerine .....	10 drops.
Water .....	300 c.c.

### SOLUTION 2.

Water .....	300 c.c.
Bichromate of ammonium .....	30 grammes.

Equal quantities of 1 and 2 are mixed together and filtered. A well-cleaned plate of glass, free from dust, is coated with a thin, even film, and dried over a spirit lamp.

The perfectly dry plate is warmed before printing, and a moderately dense positive, as free from blemishes as possible, is used. Exposure averages about fifteen minutes in diffused daylight, but it is, of course, impossible to state the exact time requisite. After printing, the plate is placed upon a piece of white card in a room where the atmosphere is rather moist, and development follows. The powder should be applied with a very soft, large, round brush, and distributed over the film with a circular motion. When sufficiently developed, the image should be vigorous and transparent. The superfluous powder should then be dusted off, and the picture coated with raw collodion, not too thick in character. When set, the film is cut through to the glass on three sides and the plate is immersed in clean water. The film will separate from the glass, excepting along the fourth side, and this will facilitate perfect washing. Clean water will suffice for washing, but a solution of borax is better; after washing, the film is transferred to the porcelain plate previously prepared to secure adhesion. A species of oil turpentine is used for the purpose. The plate may then be fired.

Instead of the bichromate powder process, the iron salts may be used for printing the picture. This process depends upon the fact that a film prepared with chloride of iron is not of itself adhesive, but it acquires this property by exposure to light. If such a film is exposed under a negative, chloride of iron is formed in the shadows, or under those parts which are more or less transparent, and, as those parts are hygroscopic, they well become tacky. If a powdery enamel colour is then dusted on, a positive picture is secured, which may be burnt in. The subsequent processes are the same as already described.

A third method for production of enamels depends largely upon the carbon process, and is also a bichromate process. Carbon pictures may be produced of the finest quality, and, as they can be developed upon plates of porcelain as a permanent support, the carbon process may be easily used for imitating enamels. It would therefore seem an easy step to substitute enamel colours for the ordinary carbon pigments, and thus obtain prints for enamelling; but, as gelatine presents difficulties in the firing, a mixture of gum and honey has been used instead for preparation

of the sensitive film, and it is probably extensively used at the present time. This medium is prepared by intimately mixing with it the enamel powder and adding the bichromate. The plates are coated and dried. A negative is used for printing, and the film is afterwards coated with collodion and immersed in water. After a short time the plate is taken out, and the collodion film is covered with a piece of moist paper and well pressed down. The film may then be lifted from the plate and developed upon the paper with warm water. It is finally transferred to porcelain. Gelatine may be substituted as a medium, the process remaining the same, and, after the picture is transferred (collodion film uppermost) and the paper removed, the film of collodion may be cleaned off by gentle rubbing with a wad moistened with acetic ether.

Photo-mechanical printing processes may also be used for the production of ceramic pictures, and they will be found of service where large quantities are required. Two different processes are available. The print may be made in the ordinary way upon a special transfer paper with a suitable ink. The colour is then dusted on. The paper, having been prepared with a collodion substratum, should be moistened and stripped off, and the picture supported upon the collodion film may then be transferred to porcelain prepared with adhesive medium and burnt in.

The following direct method may also be used:—

Paper or some other suitable material (metal, gelatine, celluloid) is prepared in such a manner that a film of collodion will not too readily strip off. The material is then coated with collodion and used for obtaining the print. The ink should consist of a suitable medium charged with very fine colour for ceramics. Iridium black, being of good covering quality, is much used for the purpose. After printing, the collodion film is stripped from the support and transferred to porcelain. Both processes are not equally suitable for the various printing methods if plucky, brilliant pictures are wanted. Consequently one must ascertain by experience which process suits best and work it according to circumstances.

The process, however, which the photographer will have readiest to hand for the production of photo-ceramic pictures, and with which he will, at the same time, be most familiar, is undoubtedly the substitution process. By its means a positive is produced by pure photography, without the use of enamel colours, and then transferred to porcelain and burnt in. It must not, however, be supposed that a photograph has simply to be transferred and then fired, which would be a great mistake. The ordinary silver image is far too delicate for the purpose, as silver in such fine division would not withstand the action of fire, and only yellowish-green traces of an image would remain. Platinum and iridium images are much more suitable for burning in, as they do not lose much of their vigour, and consequently give good results when the method is suitable.

As the direct production of platinum and iridium pictures for transfer does not seem very practicable, a different method is adopted for the purpose. A silver image is prepared in the usual manner, and converted into platinum or iridium by substitution. This may be done in two different ways, but only one of these is in general use. The positive silver image is produced in the camera by the wet-collodion process. A clear, vigorous image of pure reduced silver is obtained, that will leave nothing to be desired in respect to strength after the process of substitution. It is best to use a collodion that will yield a vigorous image by simple development without subsequent intensification, although this may be resorted to.

In order to replace the silver forming the image by one or other of the metals named, it is necessary to convert it into chloride or iodide. A five per cent. solution of mercuric chloride is best for the purpose, and with it the image is thoroughly bleached. This done, the plate is again washed, and immersed in the substitution bath. These baths resemble the ordinary toning baths, and usually contain some gold to improve the tone of the platinum or iridium. For instance, a fine purple-brown tone is obtained with the following gold and platinum bath:—

Potassium chloro-platinite.....	1 gramme.
Chloride of gold (1 in 60) .....	15 c.c.
Water .....	120 c.c.
Lactic acid .....	5 drops.

A warm black tone may be obtained with an iridium and gold bath according to the following formula:—

Iridium chloride .....	1 gramme.
Chloride of gold (1 in 60) .....	15 c.c.
Water .....	120 c.c.
Lactic acid .....	6 drops.

The toning should be continued until the whole of the silver is replaced by platinum or iridium, and the plate is then washed. The picture must be stripped from the glass for transfer, which may be done by cutting the film round the margins and immersing the plate in a weak solution of sulphuric acid, 8 c. c. of acid to the litre of water.

The stripped film is carefully washed, transferred to the porcelain, and dried. The collodion is then removed by application of a mixture of ether and alcohol. To burn in the picture it is necessary to dust the image with flux, whether the collodion be removed or not.

By the use of these well-known methods an entirely new direction has been proposed for photo-ceramics, but its attainment is beset with difficulties, compared with which those hitherto encountered are as nothing. It is in fact proposed that the process shall be used for the production of pictures in natural colours upon the principle of three-colour printing. Starting from the fact that a more or less good picture in natural colours may be produced by the exact superposition of three pictures in yellow, blue, and red, printed from specially prepared negatives, it is proposed that, by transferring and burning into porcelain three monochromatic images similarly prepared, a picture in natural colours may be obtained.

It is clear that the three necessary pictures may be produced in practice by different methods (the substitution process excepted). Probably the photo-mechanical process would be the simplest, as it would most readily permit of exact superposition of the three images; but, according to the statements of experts, the powder process, with a suitable bichromate film, is to be preferred. This requires three positives for obtaining the yellow, blue, and red prints. The negatives from which these positives are obtained must be made on suitable orthochromatic plates, and corresponding light-filters are indispensable. The operations are the same as for the three-colour printing process, and it is above all necessary to see that the colours used are in accord with the light filters. The prints are made in the usual manner, and the positives used are marked with transparent marks as a guide to superposition. The yellow image is first transferred and burnt in. When this is done, the blue image is transferred upon the former and burnt in, and finally the red. Supposing the negatives and positives are perfect, the effect will largely depend upon the transparency and covering power of the enamel colours. If they are wanting in transparency, the underlying colours will not have full effect, whilst excessive transparency would, under certain conditions, be inimical to the strength of the picture. From these considerations there should be wide scope for retouching. Retouching should be avoided as much as possible in the production of enamels, as it is far more difficult than in any other process. Consequently it is necessary to use perfect negatives and positives, also to avoid dust and to work with the utmost care.

The ceramic pictures are fired in muffled furnaces, in which a high, even temperature can be maintained. These furnaces are the most important and most costly articles in the whole process. They may be constructed in various ways, either fixed or movable. The fixed furnaces may be simply constructed with fire-clay, and heated with various kinds of fuel. The new furnaces, for work on a small scale, are movable and heated by gas, and, therefore, seem convenient and easy to use. Those of Fletcher, Russell, & Co., are well known. Coke furnaces can also be recommended. The firing requires care and plenty of experience. It is important that the requisite melting temperature should be maintained, otherwise it is impossible to enamel. A few minutes suffice to melt the colours, and the temperature should then be reduced, or the colours will lack brilliancy. The process of fusion is indicated by the matt colour of the image assuming a lustrous appearance and the surface of the plate looking as though covered with water. The colour of the picture may pass through various shades, but at last takes on its final tone.

The many purposes to which photo-ceramics may be applied, and the permanent and brilliant results which may be obtained, should be recommendations for greater attention to this neglected branch of photographic art. Doubtless there are many difficulties in the way, but the times are gone for anything to be earned in photography without some trouble. In all the fields of our art, which are easily cultivated, there is the keenest competition, and many small professionals are compelled to resort to other subsidiary employments to obtain a living, even if there is no connexion between it and photography.

From these and other considerations it is desirable to acquire some knowledge of photo-ceramic work. It may some day become fashionable, and then will be the time to profit by it; but this will only be possible to those who are familiar with the process.

J. VON NOBATH.

## PARSON'S SQUEEGEEING AND MOUNTING BOARD.

THIS apparatus, in its simplest form, consists of a base of wood or other suitable material, to which is attached, by one end, sheets of absorbent material, as blotting-paper, and over the said sheets a sheet of rubber cloth or other suitable material to resist the strain of the squeegee on the said absorbent sheets; thus the whole of the sheets are left free from one end, like leaves of a book, so that the photographic prints, or other articles to be operated upon, may be inserted between the said sheets, leaving both hands free for the operation of squeegeeing.

The baseboard, A (figs. 1 and 2), may be clamped or battened as shown,

and the sheets attached by means of a piece of wood or other suitable material, B, either permanently or in such a manner as to be easily renewed. In the latter case the strip, B, may be hinged, as shown in fig. 2, and the screws, C, C, passed through the trip and screwed into the baseboard, A, or into plates, H, H, secured to the baseboard. The said strip, B, may be unhinged, if desirable, and simply secured by the screws, C, C, or other suitable means.

When the strip, B, is clamped by the screws, C, C, it will clamp the sheets, D and E, securely to the baseboard, A.

## INTRODUCTION TO THE ALMANAC OF 2000.

THERE is nothing to justify a retrospective review of work and progress at the end of a century more than at any odd time within it. As it is, however, a conventional usage of long standing and wide vogue, and in itself, apart from all question of the time of doing, a useful and an agreeable one, we avail ourselves of the custom, and, in place of running back, as usual, simply the length of the past year, propose, in offering to our numerous friends the Year-Book of 2000, indicating more broadly some of the points of advance of the last 100 years. These are so many in number, and so marked in character, that not only would it be out of the question within the compass of one article to describe them all, but the field offers, in addition, such a revolutionary variety, running throughout the whole domain of photography, that it proves equally difficult to present them in anything of a detailed and rational order. To the better gaining of some measure of definiteness, it is therefore proposed to note only the chief advances, and to do so whilst roughly describing the procedure in taking a photograph by the departed worthies and pioneers of 100 years ago.

At that time, as most of our readers who take anything of historical interest in the art will know, a camera was necessary to the taking of a photograph, the camera being in essentials merely a light-tight box, although modified in several ingenious ways to save weight and bulk, and having about it many mechanical accessories in the shape of screws, racks, and so on, for greater convenience in using under varied conditions. In the front of this camera a lens was fitted, the rear end having a ground-glass screen, upon which the image formed by the lens was thrown for the purpose of focussing and detailed examination. When a picture—a "negative"—it was called in those days, the simple method of reversal discovered by Simpson Howard in 1827, by which the positive is directly produced, not being, of course, known—had to be taken, the ground-glass screen referred to was swung to one side, and a chemically coated glass or celluloid plate, ingeniously protected from light in a slide,

introduced into the place and plane occupied by it. A withdrawal of the protecting front of the slide, and an uncapping of the lens, resulted in an impression upon the film on the face of the plate of what it was desired to take. This was, however, not a visible, even negative, impression, but what was termed a "latent image"—most authorities of weight being now agreed that the term was thus applied to an, as yet, invisible picture, rather than in the alternative way sometimes suggested as applying to the image as one hidden or "latent," except in the so-called "dark room," and until after certain operations therein subsequently conducted had made it practicable to expose it to ordinary light. What these operations were, as well as the construction and arrangement of the dark room itself, we, fortunately, are able pretty clearly to get at through various copies of old books of instruction by bygone writers, notably one written by a Captain Abney, affording incidental proof by the way, in the title of the author, that the Government even of that day had begun to acknowledge the importance of photography as a help in warlike operations.

We would particularly recommend our younger readers, a little too prone to grumble at the very slight trouble necessary nowadays in taking a photograph, to consult one or other of these old-fashioned books, that they may to their added pleasure realise the lengths of discomfort and pains their earlier predecessors in the practice of the art had to go to. Coated plates being sensitive in an extreme degree to any light other than a non-actinic one (and even in a measure to that if it were in any way powerful), all operations had to be carried out in a room—the dark room—into which ruby-coloured light only was very sparingly admitted; and slides had to be filled, or the camera, in the event of it taking an alternative form of a magazine one, loaded, by this glow-worm style of illumination. After exposures had been made, the plates were again carried into this dismal holy of holies, and there "developed," that is, solutions of various kinds, made up mainly from empiric formulæ, were dashed over them, until the "latent" image, by chemical reactions in the film, was made visible. Yet, before door or window shutter could be opened, a further process of "fixing," or making the image permanent, had to be gone through by soaking in other solutions. Finally, well washed and dried, from the resulting monochrome negative, positive prints upon paper were produced by a crude process of contact printing, the prints themselves again undergoing in turn, before completion, processes of development, toning, fixing, and washing, as tedious and complicated as those of the mother plates.

How different is the procedure nowadays when all needed is a simple lens sliding upon a walking-stick, with a block, or book, of papers fixed in a catch at its one end. What would the old-time photographer, if privileged to revisit the scenes of his earthly labour, think of the simplicity of the process that in merely filling a hollow lens with a prepared liquid, and correspondingly preparing the paper, would admit of the possibility of instantaneously impressing upon it, at the moment of sharp focussing, a positive picture in natural colours! And this in the full eye of day, by simply sliding a lens along a rod base! Yet this has long been a commonplace; ever since the adaptation in the early forties of the classical discoveries of Professor Leslie, of Glasgow, upon the full ratios of conjugate foci.

Or what would he think, further, of the practicability of ordinary indoor work, and of photography by night? Not by his crude flashlight with its sudden and disconcerting tongue of flame—there is a good example of this flash lamp, we may add for the benefit of the curious, in Section D, Room E of the South Kensington Museum—but by the soft glow of the mica-encased actino-electric light. It is only when one remembers that, although the electric light in a rough, tentative way was being gradually introduced, yet that the light generally used at that date was gained by burning coal gas conveyed into dwelling-houses in leaden pipes, and that this gas was in turn set fire to by the still cruder expedient of scraping a phosphorus-tipped stick against a piece of sand paper to catch a spark, that the extent of our progress can to a degree be realised. The idea of dividing out white light into its component parts, and using each in a concentrated form for the particular purpose it was best suited for, did not take any commercial practical form until forty years back. We are naturally and excusably proud of the progress made in this domain of light, of such first importance to us as photographers; yet it would be premature to indulge in too deep congratulation at having reached a highest point, particularly in view of the startling, though as yet incomplete, statements that have reached us of the experiments of Goldwin Smith upon phosphorescence in the physical research laboratory of the Toronto University.

But to return to our more immediate field of photography, and what has been actually accomplished in it. One of the leading discoveries of the century, without doubt, is that of distant photography, due to the investigations by Professor Schlichter, of Heidelberg, of Hertzian rays, and their bearing upon telegraphy and tele-photography. Very hard it must have proved in older days for parents saying good-bye to sons and daughters, intent upon the freer life and lessened strain of competition in the colonies, to be denied all communication with them except through the then only reasonably practicable one of a letter a month; equally hard for the wanderers to be so completely out off from the beloved home life. Nowadays, not only can the distant Canadian or Australian farmer son or daughter communicate as readily with parents

and friends as though they were still at home, but, at the added cost of apparatus costing but a few shillings, be able to have continuous pictures at either end upon the tele-photoscopic screen of what is going on at the other. This is advance not merely to be coldly proud of as a scientific accomplishment, but to be genuinely and warmly grateful for, as reaching to the deeper realm of sentiment lying so much nearer the heart.

An advance equally marked, and with which we must conclude—reluctantly so, the subject being so pleasingly engrossing a one—is that of the marvellous development of the Röntgen rays. It was little thought, we would naturally presume, that the simple “radiographs,” or partial shadows, of the bones of the hand, first brought into the notice of a wondering world by Professor Röntgen at the close of the last century, would have developed out into so important a matter as it has. The first point to be gained was the possibility of using a lens to form a true and proportionate image; the second, a shortening of the time of exposure. The use of a material, or mixture of materials, other than glass, that would act upon the Röntgen rays as glass does upon those of ordinary light, accomplished the former object, and an isolation and concentration of the true rays the latter. What the result, combined with a further cinematographic amplification, has been, can be seen in very many directions, but more particularly as an aid to the doctor. It seems hardly credible that so short a time back as thirty years, the chief guide of the doctor in diagnosing disease in such main organs as the heart and lungs was a wooden tube with a bell-shaped expansion at each end, one of which was pressed upon the region to be examined, and the ear applied to the other to catch the sound of pulsation and movement—very much like guessing, as it were, of the life in a house by listening with the ear against a closed front door! The stethoscope has, of course, long gone out of use, and it would be a very poor consulting-room that did not possess the necessary apparatus for taking actual pictures for any desired length of time of the action of any one, or the whole, of the organs going to the making up of one's internal economy. What a bearing this has had upon remedial medicine may be gauged by a hundred different facts, not the least significant being possibly the present easy curability of consumption and angina pectoris, and the lowering of the general death rate during the last twenty years by 15·8 per cent., as shown by the last official returns.

As there is, however, no gain humanly possible without a something *per contra* to be paid, the possibility of so easily photographing private life from the streets through the house walls must be regarded as such a one in this case. Our forefathers saw great humour in the remark of Sam Weller, when he said at the trial that he “could hardly be expected to see Mrs. Bardell in Mr. Pickwick's arms through a flight of stairs and a deal door;” to us the humour is in a great measure lost in its being so easy to see through far more material obstructions. Still any such violating of private life we must very much deprecate, and it is a source of considerable satisfaction to us, and those who think with us, that an anti-Röntgen paint has been recently put upon the market, at a price well within the reach of all, a thin coating of which has, so far, proved an impenetrative protection to all within a single coating of it. This, however, is a minor side issue, suffice it that the general gain infinitely outweighs any particular loss.

The foregoing is felt to be only too brief and inadequate a reference to the mighty progress made by photography in the term of years taken into consideration; but, if it serve to direct attention to the more marked lines of progress, and thus stimulate more particular inquiry, to result in yet further advance, it will not have been penned in vain. JOHN REES.

#### PHOTOGRAPHIC PAPER.

THE action of MESSRS. Blanchet Frères, makers of the celebrated Rives paper, and MESSRS. Steinbach, manufacturers of the equally celebrated Saxe paper, in forming a coalition, and doubling the price of their respective papers, has drawn the attention of the photographic world to the mistake of leaving such an important photographic article as paper practically in the hands of these two firms, as, although Messrs. Ernest Colby, of Zwickau, have not joined them, the latter firm are hardly able to cope with the increased demand necessary to shut out the other two, which up to now have done the bulk of the trade.

In the days when albumen held almost supreme sway, these papers took the lead by reason of the composition of their sizing exercising a peculiar and most generally admired effect in the subsequent print, thus displacing many English papers which were very much used years ago; but, now that emulsion papers have come so largely to the front, the necessity of studying the sizing of the papers has gone, for these classes of papers at least, as the raw paper is enamelled with an emulsion of sulphate of baryta in a solution of gelatine; consequently the sizing of the paper cannot affect the tone and colour of the print, and there is not the slightest reason why English papers should not be used, so long as they are chemically pure. Fortunately we have a number of English papers which are quite pure, and we have also a number of firms who make a special business of enamelling paper, so there should not be the slightest difficulty in placing an English-made and enamelled paper upon the market. The necessity of enamelling the paper first is

accounted for by the fact that, were the emulsions to be poured directly on to the raw paper, they would sink right in and all definition and surface would be lost.

For albumenised paper, all that would be required is to study the sizing of the paper and make it similar to that upon the Rives and Saxe papers, which are starch-sized, where most of the English papers are sized with gelatine.

At the present time the Rives paper is made at the town of that name in France, then sent to Germany to be enamelled, and, as a large quantity of it is afterwards sent to England, the waste of time and money in travelling, &c., needs no comment.

Hardwich, in his *Photographic Chemistry*, mentions the following English papers as being pure, and suitable for printing out purposes, viz., Hollingworth's thin, Towgood's, and Evans's, of Nash Mills, Hemel Hempstead. These mills are still in existence (the latter now belonging to Messrs. J. Dickinson & Co.), and presumably could supply the paper. More recently Woodbury, in his *Gelatino-chloride of Silver Printing*, advocates Arnold's special unbleached, Whatman's thin, and Pirie's. Whatman's has been used lately, to a certain extent, for bromide work.

The paper should be composed of rags preferably, although the better kinds of esparto grass might possibly answer, wood pulp, by reason of its tendency to yellowness, being inadmissible.

The principal impurities likely to be met with in paper are: chlorine, from the chloride of lime used in bleaching the raw material, hyposulphite of soda, which is used as an antichlor, and metallic particles. Papers containing the two former are useless for photographic purposes; the latter are met with in all papers to a greater or lesser extent, even in Rives and Saxe, their presence being indicated by black spots when the paper is sensitised, causing a large amount of waste. For this reason metal rollers ought not to be used in the manufacture or enamelling of the paper, their place being taken by hardened paper-pulp rollers.

The German baryta paper is supplied in glossy, and matt (as it is called) or rough surfaces, in rolls, either by weight or measure, the usual size being 1000 metres long, or 100 kilogrammes in weight, and must be twenty-six and thirty-five inches wide, the former being the most generally used width; the length is immaterial, but the width must be strictly adhered to, as the sizes of the finished paper and likewise the machinery by which they are coated, &c., are based upon this width. The paper is also supplied with mauve, pink, and white surfaces, the colour being obtained by dyeing the baryta emulsions to the required shade, with a fast and direct (as it is known in the colour trade) dye, before enamelling the paper.

It is, of course, necessary that the paper should be turned out with the enamel as nearly uniform as possible, for this is one of the great defects in the present German papers, and, unless the enamelled paper is uniform, it is practically impossible to make the sensitised paper so.

It is also absolutely necessary that the baryta enamel should be chemically pure as well as the paper, as it is upon this that the emulsion depends, to a large extent, for permanency. Some experiments which were tried with collodio-chloride upon British enamelled paper show the necessity for a perfectly pure enamel; in one case the sensitised paper turned blue in less than twelve hours in the dark; still, these papers are of very good quality and surface, and all that seems necessary is that, for photographic emulsion work, all the ingredients of paper and enamel shall be perfectly pure, and, instead of being calendered with hot metal rollers, paper-pulp ones shall be used, and the polishing be done with rapidly revolving brushes.

The enamel for collodio-chloride and gelatino-chloride varies slightly, the gelatine substratum for the latter process requiring to be hardened somewhat to prevent the warm emulsion from sinking into it, which, of course, is not necessary with collodio-chloride, as ether-alcohol does not affect gelatine in the dry state. The hardening is accomplished by adding to the baryta emulsion either common alum, chrome alum, or formaldehyde, commonly sold as formalin, the latter being the best, as chrome alum gives a somewhat greenish tinge to the emulsion, and contains a large amount of sulphur, which is a very undesirable item, the respective formulae of chrome alum reading:—

and common or potash alum,

A section of the German press has lately made accusations of yellowing and fading against collodio-chloride, but, as was recently mentioned in THE BRITISH JOURNAL OF PHOTOGRAPHY, this has not been found to be the case in England, for the general experience has been that it is practically permanent, even under unfavourable conditions. The afore-mentioned article lays the blame upon the baryta paper, probably due to impure materials, the writer of the article trying three baryta papers enamelled by a like number of different firms, with three dissimilar results. Still, it is a fact known to chemists that baryta, under some conditions, is liable to turn yellowish-brown by the action of ether-alcohol. This might account for the yellowing, but not for the fading, and suggests the employment of some other substance, such as kaolin, instead of baryta, for the enamel, though, on the other hand, it is said by some chemists that baryta, although imperfect, is the best known substratum for

these papers. The fading mentioned is almost sure to be due to some impurity in the baryta emulsion.

Photography has become considerably more than a mere amusement or scientific recreation, and is a necessary adjunct of business life, playing, as it does, an important part in many trades and professions, where copies of machinery, houses, &c., are required, and there is always a constant demand for the paper, the business done in enamelled paper alone in England running into many thousands of pounds annually for photography only, besides large quantities being used for collotype and the better class of printing; so there is no question of there not being a demand for it, and any English maker placing such a paper upon the market need not be afraid of being unable to find customers, even at the same price as the German enamelled papers, as at the present time it takes from three to six weeks to obtain them from Germany, and sometimes even this period is exceeded, so that, should English manufacturers of emulsion papers experience an exceptional demand, and their supply of enamelled paper from some unforeseen reason give out, their predicament may be more easily imagined than described. I may mention that such circumstances have arisen more than once, so that I have no hesitation in saying that English photographic-paper manufacturers would gladly welcome an English-manufactured and enamelled paper, even if it meant no saving of money upon the paper, for the convenience and security of being able to obtain it when wanted.

The drawback possibly experienced by English firms who would, perhaps, manufacture the paper may be accounted for by the fact that they are unable to get reliable information as to the requirements of the trade; that is a difficulty easily got over, for what is possible in Germany should be, and could be, possible in England. It is a very strange thing that the paper support for collodio chloride, and gelatino chloride (both of which are English inventions) should have been allowed to be entirely produced, if not invented, by Germans; but, unfortunately it is an acknowledged fact that English manufacturers are very often slow to recognise requirements which are perhaps a little outside the usual run of their business, and even the albumenising has been largely allowed to fall into German hands; but, should English paper-manufacturers read the English photographic trade journals, as no doubt many of them do, they should be able to see by the articles which have recently appeared in these papers, and notably those in *THE BRITISH JOURNAL OF PHOTOGRAPHY*, that there is a large and lucrative business to be done by them in photographic paper, as this coalition has upset, not only England, but Germany and other parts of the Continent as well. Messrs. Schoeller & Schering have grappled with the subject in Germany already, and it is to be hoped, for the sake of English photography and English commerce, that some English firm will take the matter up, keeping money and employment in the country, and relieving photography of a monopoly which has badly abused it. Even evils sometimes have their good side, and, should this very desirable consummation become an accomplished fact, the German-French "corner" will not have been formed in vain.

C. T. SUTTON.

#### GOLD TONING WITH SULPHOCYANIDE FOR AMATEURS.

Among the many arithmetical puzzles with which the photographer is confronted there is hardly a more difficult one than that of realising the real meaning of the chaotic formulæ given by different makers for the simple process of toning.

I have studied the directions sent out with different brands of paper, and have endeavoured to arrange hints for the preparation of the bath in comprehensible terms.

#### SOLUTIONS.

**Gold.**—Break a tube of gold chloride (1 gramme) into 100 c. c. of water.—Result, a 1 per cent. stock solution. Take 1 part stock and 9 parts water, obtaining a 1 per 1000 mixture for use. 100 c. c. in a small bottle is a convenient quantity to prepare at once.

**Sulphocyanide.**—Place 10 grammes of sulphocyanide in a foreign medicinal water bottle, and 1 litre (1000 c. c.) of water for 1 per cent. stock. In a similar bottle dilute 100 c. c. of stock with 900 c. c. of water, thus obtaining a 1 per 1000 solution.

For each quarter-plate print take the quantities named in the table opposite the selected colour, and for other sizes and quantities of paper in like proportion.

Colour.	Gold chloride, 1 per 1000	Sulphocyanide, 1 per 1000.
	c. c.	c. c.
Red .....	·7	7
Reddish brown .....	1·0	10
Brown .....	1·5	15
Warm purple brown .....	2·0	20
Cold purple brown .....	2·5	25
Cold purple black .....	5·0	50

Add as much water as is necessary for easy manipulation.

Until experience is gained it is best to make a bath of sufficient materials to tone a single print in one dish, and exhaust the gold with it. Personally, I do not find that any saving in time is effected by operating on more than one print at a time.

For fixing, use one part saturated solution of hypo and two parts water.

Weighing hypo is a needless refinement. For plates use one part each of saturated solution of hypo and water.

C. L. HETT.

#### WILKINSON'S PRINTING FRAME.

MESSRS. WILKINSON say: In a photographic printing frame as *a*, we form semicircular recesses, *b*, preferably at opposite corners, as shown in fig. 1. We secure one end of each of the pressure springs, *c*, and *c*<sup>1</sup>, to one of the sides of the frame by means of a stud, *d*, so that said springs may swivel, the free end of each spring being retained in a groove, *e* or *e*<sup>1</sup>, formed in the interior edge of the opposite side of the frame. In order to insert the free ends of the aforesaid pressure springs into the grooves, *e* or *e*<sup>1</sup>, said free ends are pressed down the semicircular recesses, *b*, and

passed into the grooves, *e* or *e*<sup>1</sup>, respectively. When the ends of the springs are required to be withdrawn from the aforesaid grooves, *e* or *e*<sup>1</sup>, they are pressed round until they come to the semicircular recesses, *b*, as indicated by dotted lines in fig. 1, when they will rise and release the flap, *g*. In a modification of our invention, shown in fig. 3, the compression springs, *c* and *c*<sup>1</sup>, are pivoted in the centre, and semicircular recesses, *b*, are cut in each corner and at or near the centre of the inner side of the frame, each of the ends of said springs being retained in the grooves, *e*<sup>x</sup>, and can be removed in the manner before described.

#### THE MEASUREMENT OF ATMOSPHERIC ACTINISM.

[Abstract Translation from *Chemiker Zeitung*.]

THE importance of the systematic registration of the actinic value of daylight under the varying conditions of climate is a question upon which most photographers will be agreed. The abstract of a paper on this subject, read before the Chemical Association of Christiania by Professor John Sebelien, appeared in the issue of the *Chemiker Zeitung* for November 2, and is worth more than passing attention. The author criticises the various types of actinometer which have been proposed for measuring the actinic intensity of daylight, from the hydrogen and chlorine actinometer of Draper, introduced in 1843, down to instruments of more recent date. Draper's instrument, even when greatly improved by Bünsen and Roscoe, had the defect of the glass tube (in which the gases were contained) absorbing some of the ultra-violet rays, whilst the exothermic character of the reaction was an additional source of error. Far simpler in use, and just as accurate in results, was the use of chloride of silver paper, prepared according to the standard directions of Bunsen. After describing Wiesner's method, which was a simplification of the methods involving the use of a pendulum photometer, the author stated that, in conjunction with P. Solleid, he had been studying photo-chemical

variations in Norway, using a method due to the combined researches of Eder and Wiesner, which gave a number of isolated tests of the actinic energy. In order to obtain an estimate of the total action throughout a long period, such as a day or year, the figures bounded by the curves obtained were drawn on stiff, homogeneous paper, cut out, and the paper weighed. This gave results which were sufficiently accurate. For making estimation of photo-chemical intensity over a considerable period the scale photometer of Vogel would be suitable were it not liable to errors which, in the opinion of the author, are not easily avoided; the result obtained by exposure to a whole day's radiation does not agree with that obtained if the exposure were divided into hourly, two-hourly, or even half-daily intervals. It was preferable to use for these purposes solutions which underwent chemical change on exposure to light. The photo-decomposition of chlorine water into hydrochloric acid and oxygen (discovered by Berthollet over 100 years ago) had been used by Saussure for actinometric measurement, but, like the photo-decomposition of solution of potassium iodide, had not been used nearly so widely as the alteration in light of oxalic acid solution or oxalate in some form or other. Duclaux had used a vingti-normal solution of oxalic acid for taking actinometric observations in various parts of France and Africa, but the author's experience of the method was that it was not very sensitive. In some recent experiments he had made he found that the strength of 50 c.c. of N 20 oxalic acid solution, when exposed in glass flasks, 10 cm. in depth, for one or two days, scarcely altered, whilst under the same circumstances Wiesner's and Eder's methods gave a high photo-chemical intensity. Marchand's method of using the oxalic acid in the form of iron salt, was open to the objection that the effect of temperature and gradual concentration is not known, whilst the colour of the solution alters during the progress of the reaction. Since the commencement of the present year the author has used Eder's solution of ammonium oxalate and mercuric chloride for daily estimations of chemical intensity at the Agricultural High School of Aas, near Christiania.

The solution decomposes in a similar manner to oxalic acid, but with separation of the mercury, as mercurous chloride. The precipitate which separates in the course of a given exposure was collected on a dried filter and weighed. By means of Eder's tables, corrections for the temperature and change of concentration can be applied. By changing the flasks from hour to hour, the daily periods of intensity can be estimated by Eder's solution; and from these figures the author shows that the photo-chemical intensity bears no direct relation to the duration of sunshine or the clearness of the sky, nor in general to the usual meteorological factors. It was remarkable—and the fact is of great interest to the landscape photographer—that this recorded intensity reached a maximum in March, on a day when the sky was clouded and snow and rain fell, whilst some days previously, in far clearer weather and with bright sunshine, the photo-chemical intensity was much smaller.

### GRAINING BLOCKS FOR PHOTO-MECHANICAL PRINTING.

Mr. PITMAN's invention relates to an improved method of and means for producing "originals" for use in preparing blocks suitable for printing.

In ordinary "block" printing it has hitherto been difficult to produce "half-tone" effects. The object of the present invention is to render such effects easy of attainment, and in an economical manner.

In the production of an "original" according to my improved method, says Mr. Pitman, I prepare a mould having an inner face composed of a number of minute pyramids, same being produced by means of V-shaped parallel grooves arranged in two series, the one crossing the other at right angles, or thereabouts. With the aid of this mould I form a plate composed of a black substance, such as a mixture of wax with black lead; the surface of the plate consisting of a number of minute pyramids corresponding with the inner surface of the mould. The serrated surface of the plate is then served with a coating of a white substance, such as plaster of Paris, the thickness of the coating being sufficient to entirely fill the V-shaped grooves.

The serrated surface may also be produced by scoring the face of the plate, or by means of pressure, or with the aid of rolls having serrated surfaces.

Upon the coating becoming set, the plate is ready for the reception of the design, which may be etched or otherwise depicted thereon in pencil or other material.

By scraping, dissolving, or otherwise reducing the coating to a greater or less depth, according to the nature of the design, the apices of the pyramids become apparent, and impart to the surface so reduced a minutely speckled appearance, amounting to a "half-tone" effect. If the reducing process be continued, more of the black substance and less of the white coating becomes visible as the pyramids become more blunted, the result being a deeper "tone."

It will be readily perceived that the design is produced in a series of minute black spots or specks on a white ground, these specks varying in size and in distance apart according to the severity of the reduction process, half-tone and deep shadow effects being thus obtained.

The plate with serrated surface may be formed of the white substance, and the coating may be composed of the black substance, in which case

the scraping or reduction process would bring into view the high lights, instead of the shadows.

Having obtained the original as above described, the printing block may be prepared therefrom by means of photography according to any of the methods usually practised.

## Our Editorial Table.

THE CADETT "SAFE LIGHT."

Cadett & Neall, Ashted, Surrey.

We have received from Messrs. Cadett & Neall one of their safe lights, the use of which, it is pointed out, is a *sine-quâ-non* with the Spectrum plates, unless the latter are manipulated in total darkness. We gather that the demand for the Spectrum plates is largely on the increase, and it is anticipated that that demand will be further augmented by the introduction of these safe lights. Each safe light, which, visually, is a very deep red, produced by a mixture of differently coloured glasses, is spectroscopically tested before it is sent out from Messrs. Cadett's works. It is certainly a step forward in the niceties of practical working when the makers of colour correct plates indicate with precision the light in which those plates may be manipulated.

THE CADETT P.O.P.

Cadett & Neall, Ashted, Surrey.

A NEW gelatino-chloride printing-out paper, made in three tints, mauve, pink, and white, has just been put on the market by Messrs. Cadett & Neall. We hope to have an early opportunity of striking some prints on this paper, the latest production of the energetic Ashted house. In the meanwhile, an examination of the samples submitted to us show the paper to have been well and carefully prepared. We append the working instructions for it:—

Print a shade darker than is required in the finished print.

Before toning, wash well for ten minutes in running water; be careful to put the prints separately into the water.

If necessary, in hot weather, the prints may be soaked for a few minutes in a five per cent. solution of alum, after which they should be again washed in running water for ten minutes.

Toning Bath.—Stock solution of gold: Break a 15 grain tube of gold chloride in a stoppered bottle; add 15 drachms of distilled or boiled water. Take of

Ammonium sulphocyanide .....	35 grains.
Water, distilled or boiled .....	20 ounces.
Stock solution of gold .....	2½ drachms.

After toning, wash for a few minutes, and fix in bath of hypo containing 4 ounces of hypo to 20 ounces of water; leave the prints for about ten minutes in the fixing bath.

After fixing, wash well in running water for about an hour. On no account leave the prints in still water.

### LE DÉVELOPPEMENT DE L'IMAGE LATENTE EN PHOTOGRAPHIE.

A. SEYEWETZ: Gautier-Villars, Quai des Grands-Augustins, 55, Paris.

THE work of M. Seyewetz will be of much use to the photographic student who wishes to become acquainted with the chemical aspect of the problem of development. It treats of the old and the modern developers and discusses their merits and defects. Amidst the confusion of ideas concerning the advantages of many recent introductions, the following quotation is worthy of note: "Pyrogallie acid in presence of acetone and sulphite of soda, diamidophenol, diamidoresorcin, and paramidophenol are types of developers difficult to surpass, according to our opinion, and they possess substantial advantages in comparison with others. The only new developers that are likely to supplant the old, are those that might supplement in a certain measure the action of light and, thus facilitate the development of an under-exposed plate. Unfortunately, there seems to be no prospect of attaining this result at present, as we have shown that, however energetic the reducing power of the developer, they all produce rigorously the same amount of detail if the exposures are identical."

### LEHRBUCH DER PHOTOGRAPHISCHEN CHEMIE UND PHOTOCHEMIE.

By ALEXANDER LAINER.

R. Lechner. K. & K. Hof und Universitäts-Buchhandlung, Vienna.

This work forms Volume VI. of Lechner's Photographic Library, and deals with the methane derivatives. It has been compiled with considerable care, and will, doubtless, become a standard work of reference. The uses of the various compounds in photography are very completely described.

PERHAPS the most favourable thing we can say of the *Photographer's Pocket Diary* for 1899 is that we intend making daily use throughout the year of the copy that has been sent us for review. The diary is, as

hitherto, compiled by Mr. E. J. Wall, who has condensed a great deal of valuable information into the little book, which contains the usual diary spaces, blanks for recording exposures, and so forth. It is published by Messrs. Charles Letts & Co., 22, and 24, Tabernacle-street, E.C.

THE *Entrevue Annual* for 1899, edited by Mr. W. H. Combes, and published at 6, Catherine-street, Strand, is full of clever caricatures by Mr. Alfred Bryan and stories and verses by well-known writers. The *Annual* appeals to everybody interested in stage and music-hall matters—a very large public.

#### RECENTLY ELECTED OFFICERS OF SOCIETIES.

(Received too late for the ALMANAC.)

**AUCKLAND PHOTOGRAPHIC CLUB.**—Established 1885. Meetings held at the Club Rooms, Grey-street. *President:* Dr. J. Logan Campbell. *Vice-Presidents:* Messrs. J. R. Hanna, J. Martin, and E. A. Payton. *Treasurer:* Mr. W. Gatenby. *Secretary:* Mr. H. R. Arthur, c/o Auckland Gas Company, Limited, Wyndham-street.

**CAPE TOWN PHOTOGRAPHIC CLUB.**—*Hon. President:* Dr. Gill, C.B., F.R.S. *Vice-President:* Dr. Muir. *Committee:* Messrs. T. H. Watson, A. Gracie, G. Ainslie, J. Denham, E. J. Steer, A. McLeod, A. J. Fuller, and J. P. Edwards. *Hon. Secretary and Treasurer:* Mr. H. Bishop.

**DOVER PHOTOGRAPHIC SOCIETY.**—*President:* Rev. Turberville Evans. *Committee:* Captain Gordon McDakin, Messrs. Mowbray Gray, H. Peake, and J. J. Goulden. *Treasurer:* Mr. R. M. Ewell. *Hon. Secretary:* Lieut.-Colonel Cockburn Curtis, 21, Leyburn-terrace.

**DUNEDIN PHOTOGRAPHIC SOCIETY.**—Established 1870. Meetings are held at the Rooms, Liverpool-street, Dunedin. *President:* Mr. C. W. Kerr. *Vice-Presidents:* Messrs. A. Hamilton and R. A. Ewing. *Committee:* Mr. W. Williams, J. C. Thomson, A. J. Barth, F. J. Monnon, G. Crichton, and P. Laine. *Secretary and Treasurer:* Mr. J. Skottowe Webb, c/o National Insurance Company, Dunedin, New Zealand. *Recording Secretary:* Mr. W. Livingstone.

**GLASGOW PHOTOGRAPHIC ASSOCIATION.**—Established 1862. Meetings held in the Philosophical Society's Rooms, 207, Bath-street, Glasgow. *President:* Mr. John Stuart. *Vice-Presidents:* Messrs. William Lang, F.C.S., and J. Craig Annan. *Council:* Messrs. Robert Dodd, J. E. Hanbidge, George Mason, A. Lindsay Miller, J. C. Oliver, and Archibald Watson. *Treasurer:* Mr. George Bell. *Secretary:* Mr. Charles Macdonald, 100, West Regent-street, Glasgow.

**HAND-CAMERA POSTAL CLUB.**—Established 1898. The object of the Club is to encourage the use of the hand camera as an instrument of pictorial work. *Hon. Secretary:* Mr. P. E. Bradshaw, 12, Victoria-parade, Ramsgate.

**HAWKES BAY CAMERA CLUB.**—Established 1895. Meetings are held at the Club Room, Regent-street, Napier. *President:* Dr. A. Milne-Thomson. *Vice-President:* Mr. F. Nelson. *Committee:* Messrs. T. B. Bear, S. E. Cooper, H. W. Harrington, A. A. Kennedy, J. K. Newton, and F. J. Shanly. *Treasurer:* Mr. G. Nelson Pierce. *Secretary:* Mr. W. Beswick, C.P.O.

**ISLE OF THANET PHOTOGRAPHIC SOCIETY.**—Affiliated to the Royal Photographic Society of Great Britain. *President:* Rev. Canon H. Bartram, M.A. *Vice-Presidents:* Rev. C. E. Eastgate, M.A., Rev. W. E. Allen, M.A., Messrs. G. Dowker, F.G.S., and J. H. Forwalk, F.R.H.S. *Committee:* Messrs. E. Deacon, A. D. Sackett, J. Savage, C. J. Scott, P. Solly, and A. Vizar. *Hon. Lanternist:* Mr. J. H. Forwalk. *Assistant Lanternist:* Mr. E. Deacon. *Hon. Librarian:* Mr. B. Barnett. *Delegate to the Royal Photographic Society:* Mr. J. C. Goldsack. *Hon. Secretary and Treasurer:* Mr. J. C. Goldsack, Llanberis, Grove-road, Ramsgate.

**NORTHERN TASMANIA CAMERA CLUB.**—Established 1889. Meetings held at the Club Room, Albert Hall, Launceston, Tasmania. *President:* Mr. William Gibson. *Vice-Presidents:* Messrs. F. C. Birchall, R. C. Kermode, and W. H. Twelveteens. *Committee:* Messrs. H. B. Brownrigg, R. Lewis Parker, and John Sparrow. *Secretary and Treasurer:* Mr. F. Styant-Browne, 112, Brisbane-street, Launceston, Tasmania.

**N.S.W. RAILWAY AND TRAMWAY CAMERA CLUB.**—Established 1894. Meetings held at the Railway Institute, Sydney, N.S.W. *President:* Mr. H. McLachlan. *Vice-President:* Mr. H. Carruthers. *Committee:* Messrs. F. Peterson, T. Marsh, C. S. Robins, and A. J. Leslie. *Treasurer:* Mr. J. Paterson. *Secretary:* Mr. J. Scouler, Railway Institute, Sydney, N.S.W.

**OLDHAM PHOTOGRAPHIC SOCIETY.**—Established 1887. *President:* Mr. W. A. Nash. *Vice-President:* Mr. R. T. Taylor. *Committee:* Messrs. S. Ashton, J. Brooks, J. Chadwick, J. W. Cooper, J. S. Dronfield, J.P., and J. T. Whitehead. *Librarian:* Mr. J. Fullalove. *Treasurer:* Mr. James Whitehead. *Hon. Secretary:* Mr. T. Widdop. *Assistant Secretary:* Mr. J. A. Newton.

**PHOTOGRAPHIC CLUB.**—Established 1879. *Trustees:* Messrs. Frank Haes and F. A. Bridge. *Committee:* Messrs. A. Bridgman, F. Dowell, A. Mackie, H. Müller, J. Nesbit, Hutton P. Smith, H. Snowden Ward, and J. R. Williams. *Librarian and Curator:* Mr. Charles Wallis. *Hon. Secretary and Treasurer:* Mr. W. R. Stretton, 4, Queen-street-place, London, E.C.

**PHOTOGRAPHIC CLUB OF BALTIMORE CITY.**—Organized 1891. Meetings held at 709, Madison-avenue. *President:* Dr. Frank Slothower. *Vice-President:* Mr. Percy M. Reese. *Directors:* Dr. Frank Slothower, Messrs. Percy M. Reese, L. T. Norris, E. M. Barker, F. W. McAllister, Jordan Stabler, and J. Plumer Bigham. *Treasurer:* Mr. E. M. Barker. *Secretary:* Mr. J. Plumer Bigham, 609, North-avenue West, Baltimore, Maryland.

**QUEENSLAND AMATEUR PHOTOGRAPHIC SOCIETY.**—Established 1883. Meetings held at the Courier Building, Brisbane. *President:* Dr. John Thomson,

*Vice-Presidents:* Dr. Wheeler, Messrs. C. J. Pound and H. W. Mobaby. *Committee:* Messrs. D. McTaggart, F. Nicholls, F. E. Davies, and Dr. Love. *Treasurer:* Mr. J. L. Kinloch. *Secretary:* Mr. W. C. Voller, 88a Queen-street, Brisbane.

**SACRAMENTO CAMERA CLUB.**—Established 1895. Meetings held at the Club Rooms, 504, J-street. *President:* Mr. Ferdinand Kohler. *Vice-President:* Mr. S. B. Nourse. *Directors:* Messrs. Ferdinand Kohler, S. B. Nourse, W. G. Woods, R. P. Burr, R. B. Prideaux, W. E. Cogswell, and J. J. Gormley. *Treasurer:* Mr. R. P. Burr. *Secretary:* Mr. W. G. Woods, 420, J-street, Sacramento, California.

**SOUTH AUSTRALIAN PHOTOGRAPHIC SOCIETY.**—Established 1885. Meetings held at the Chamber of Manufactures, North-terrace, Adelaide. *President:* Mr. C. L. Whitlam. *Vice-Presidents:* Messrs. R. F. Griffiths and Andrew Scott, B.A. *Committee:* The Executive Officers, and Messrs. A. W. Marshall, A. H. Kingsborough, and R. B. Adamson. *Treasurer:* Mr. S. P. Bond. *Secretary:* Mr. J. Gazard, Mutual Chambers, 111, King William-street, Adelaide. *Librarian and Assistant Secretary:* Mr. J. D. Dixon.

**SOUTH SHIELDS PHOTOGRAPHIC SOCIETY.**—Established 1894, Reorganized 1898. Meetings held in the Y.M.C.A. Rooms, South Shields. *President:* Mr. J. Davenport. *Vice-Presidents:* Messrs. W. Parry, A. E. Cowling, W. Hoare, A. J. Hunter, and J. G. Finlayson. *Committee:* Messrs. W. J. Brock, N. Blackburn, M. H. Sadler, A. Hoare, W. Beck, and H. Clark. *Steward:* Mr. T. E. Taber. *Hon. Treasurer:* Mr. W. Short. *Hon. Secretary:* Mr. J. Kyle, 16, Pier-terrace, South Shields.

**WAKEFIELD PHOTOGRAPHIC SOCIETY.**—*President:* Mr. H. M. Briggs. *Vice-Presidents:* Messrs. C. Miles and W. Holmes. *Committee:* Messrs. Norwood, Stanfield, Shaw, Chaplain, Cass, and Grainger. *Treasurer:* Mr. A. H. Roberts. *Hon. Secretary:* Mr. R. Robson, Dunelm-terrace, Sandal, Wakefield.

**WELLINGTON CAMERA CLUB.**—Established 1892. Meetings held at the Club Room, Exchange Buildings, Lambton Quay. *Patron:* His Excellency Earl of Kanfurly. *President:* Mr. A. de Bathe Brandon. *Vice-Presidents:* Messrs. J. McLellan and A. C. Gifford. *Committee:* Messrs. R. L. Mestayer, T. Pringle, B. Joyce, G. W. Bartrop, S. G. Watson, and J. Polson. *Auditor:* Mr. C. W. Stevens. *Judge:* Mr. Malcolm Ross. *Treasurer:* Mr. T. M. Hardy. *Secretary:* Mr. J. A. Heginbotham, Kilbirnie, Wellington, New Zealand.

**WORKING MEN'S COLLEGE PHOTOGRAPHIC CLUB.**—Meetings are held in the Lecture Hall at the College and in the Club's Dark Rooms, Latrobe-street, Melbourne. *President:* Professor Kernot, M.A., C.E. *Vice-Presidents:* Messrs. F. A. Campbell, C.E., T. C. Camm, and A. J. Campbell. *Committee:* Messrs. H. P. Bennett, T. J. Eastham, W. Stutterd, H. Vanheems, and F. Gray. *Hon. Instructor:* Mr. L. Hart, F.R.M.S.—*Lantern Engineer:* Mr. A. B. Sturtevant. *Librarian:* Mr. J. Glover. *Hon. Treasurer:* Mr. E. C. Moore. *Hon. Secretary:* Mr. Arthur J. Relf, Government Printing Office, Melbourne, or 33, Palermo-street, South Yarra. *Assistant Secretary and Press Correspondent:* Mr. J. P. Campbell.

## News and Notes.

**PHOTOGRAPHIC CLUB.**—Wednesday evening, January 11. Members' Open Night.

A new work by Dr. Hermann Vogel, who died recently, is announced by Messrs. Kegan Paul under the title, *Experimental Physics*.

MR. G. SCOTT, of Cimiez, asks: "Can you, or any of your readers, inform me if Dr. Wallich is still alive, and who possesses the negatives taken by him some years ago?"

**ROYAL PHOTOGRAPHIC SOCIETY.**—Ordinary Meeting, January 10, at eight p.m. "Some Remarks on Recent Papers concerning the Latent Photographic Image and its Development," by C. H. Bothamley, F.I.C., F.C.S.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—On Thursday next, at eight o'clock, Mr. Howard Farmer will read a paper, "Abolishing the Dark Room." The Hon. Secretary will be pleased to see any one interested in the subject at the White Swan, Tudor-street, Whitefriars.

**ERRATUM.**—Messrs. J. J. Griffin & Sons write: "In converting the formula for Velox into grammes the figures as printed in your ALMANAC, page 1044, are incorrect. The amount of metal should be 1.6 grammes, instead of 16 grammes, as printed. As this is a serious mistake, and might lead to inconvenience, we are taking the liberty of calling your attention to the matter, so that you may correct it in future editions."

**DURHAM CITY CAMERA CLUB.**—At the Royal County Hotel, Durham, on Thursday, December 29, a complimentary dinner was given and presentation made to Mr. Robert Hauxwell by the members of the above Club. The presentation comprised a very handsomely furnished polished mahogany writing table and desk, with brass handles, made by Mr. George Peacock, of Elvet Bridge, from a special design. A silver plate bore the following inscription: "Presented to Robert Hauxwell, Esq., Honorary Secretary, by the members of the Durham City Camera Club. December, 1898."

THE last issue of the Vienna weekly, *Die Wage*, contains a conversation with M. Jan Szczepanik, a Polish inventor, regarding a new discovery which is claimed to be of considerable military value. From this it appears that M. Szczepanik has constructed an apparatus which is set in action simply by light. Starting from this novel principle for the liberation of energy, M. Szczepanik has made a bomb which contains this apparatus in its internal mechanism, so arranged that it causes the bomb to explode immediately a stream of light is thrown upon it by a second apparatus designed for the purpose.—*Reuter*.

**WATER LACQUERS.**—The group of the water lacquers embraces only a few little-used lacquers. Below are some receipts. 1. *Shellac Water Lacquer.*—Boil 28·5 grammes of shellac and 42·75 grammes of borax in 0·564 litre of water until the shellac has dissolved. If bleached shellac is used, a white colour is obtained, with orange shellac a light brown one. This varnish gives a good binding agent for water colours, and is also a useful paper varnish. It dries with a handsome lustre and hard surface which is waterproof. By the addition of aniline colours soluble in water, the lacquer can be tinted as desired. 2. *Enamel Lacquer.*—Mix 0·564 litre of albumen with 0·564 litre of water. For preservation, add a little carbolic acid or salicylic acid. Instead of the albumen, dried albumen may be employed, of which 28·5 grammes are dissolved in 0·564 litre of water, but the colour is less clear. This varnish dries with good gloss. By drying in hot air it becomes more resistive to water. 3. *Blue Lacquer.*—Dissolve 1 pound of good pale glue in 9 litres of water, the colour being entirely dependent on the quality of the glue. Good white gelatine gives a white colour, while brown glue yields a yellow one. Solution accomplished, add (but only directly before use) 28·5 grammes of potassium bichromate, which renders the surface water-tight. As said, the potassium should only be added closely before use, else the solution will be converted into a gelatinous, stiff mass. This mixture constitutes the basis of many leather varnishes. For preservation, the addition of a little thymol or borax is commendable. 4. *Crystal Water Lacquer.*—Dissolve 450 grammes of good white gum arabic and 450 grammes of glucose in 1629 litres of water. This solution dries hard and glossy.—*Färben Zeitung.*

Re HENRY TAYLOR, photographer, Watton, Norfolk.—The public examination of the above-named debtor took place at the last sitting of the Norwich Bankruptcy Court, when a statement of affairs was filed showing liabilities amounting to 264*l.* 5*s.* 7*d.*, and a deficiency of 137*l.* 0*s.* 11*d.* The debtor, in reply to questions, said he was formerly in a large way of business in Soham, Cambs but, being sold up, he, in 1892, removed to Watton, where he lived with his wife, who had a private income, as a private resident. He commenced business at Watton at Michaelmas, 1893. He had not been successful however, and, his wife dying, his expenditure exceeded his income, and he was compelled to file his petition in bankruptcy. He admitted that he had done a little in the way of betting. He did not think that any part of his misfortunes had been caused through betting. During the past three years he had never had a bet to any considerable extent. The last bet he had was in October last, but it was only for a small sum. The Official Receiver: I put it to you that the money did not come out of your pocket, but out of the pocket of your creditors? Debtor: Yes, but it was for a very small sum. The Official Receiver: Did you consider yourself justified in speculating with your creditors' money in this manner, within a month of your bankruptcy? Debtor: I did not anticipate bankruptcy, or I should not have done it. The Official Receiver: I see you attribute as one of the causes of your present position your having been waylaid and robbed. Debtor: Yes. The Official Receiver: You say that at London Bridge Station you were set upon by seven or eight men and robbed of 38*l.* Debtor: Yes. The Official Receiver: Did not you make any complaint to the police? Debtor: I did not complain to any one. I was nearly killed, and got out of it as soon as I could.—The debtor was eventually allowed to pass.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

January.	Name of Society.	Subject.
9	Bradford Photo. Society	In Wordsworth's Country: The Poet Interpreted by the Photographer. Percy Lund.
9	Camera Club	Our Cruise to the Golden Horn. Rev. N. R. Fitzpatrick, M.A.
9	Kingston-on-Thames	Composition and Selection of Subjects in Pictorial Photography. A. Horsley Hinton.
9	Oxford Camera Club	Various Printing Processes. J. B. Wilson.
10	Hackney	Holations: Suggestions for its Prevention. C. H. Oaklen.
10	Iale of Thanet	Architectural Photography. John A. Avery.
10	Lewisham	Lantern Evening.
10	Royal Photographic Society	Some Remarks on Recent Papers concerning the Latent Photographic Image and its Development. C. H. Bothamley, F.I.C., F.O.S.
10	Shropshire	Demonstration: The Development of the Photographic Negative. Wallace Heath.
11	Croydon Camera Club	A Practical Comparison of Flash Light. Messrs. J. Smith, Noakes, and Kough.
11	Leeds Camera Club	With Cycle and Camera in Lakeland. G. Thistlewaite.
11	Photographic Club	Members' Open Night.
12	Ashton-under-Lyne	Class for Beginners: Negative-making.
12	Camera Club	Deep-sea Fishing. Dr. C. S. Patterson.
12	Darwen	Smoking Concert.—Irish Slides.
12	Gospel Oak	The Chemistry of Photography. J. B. Davidson, M.P.S.
12	Liverpool Amateur	Demonstration. Dr. Charles A. Kohn.
12	London and Provincial	Abolishing the Dark Room. Howard E. Farmer.
12	Oldham	Lantern Lectures: Prize Slides.
12	Southport	Southport Society of Natural Science and S.P.C. Joint Soiree.
12	Woolwich Photo. Society	Slides contributed by Affiliated Societies, Set B.
13	Croydon Microscopical	On Lantern Slide Making. A. P. Hoole.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 29, 1898.—Mr. E. W. Parfitt in the chair.

Mr. PHILIP EVERITT brought forward what he thought were some curiosities in exposures. The subject of the photograph—a violin—was really an orthochromatic subject, but an ordinary (Castle) plate was used. The colour of the instrument was of a red and yellow nature, such a one as to give rise to some doubt as to the correct exposure. He stated that guesses which had been made ranged from three seconds to as many minutes. The instrument he placed about three feet from a window, in a side light of a fairly good quality for the present time of year, the lens being stopped down to *f*-10. The two prints he passed round were full of the detail of the texture of the wood, and the exposure given was twenty-five minutes on second trial. No colour filter of any kind was employed, but the rendering was an excellent one.

Mr. H. C. RAPSON said that, working under the same conditions very recently, with a light of a similar quality, upon an extremely yellow oil painting, he got a good rendering with fifteen minutes' exposure. The picture was twice the distance from the window named by Mr. Everitt, and an orthochromatic plate with a deep yellow screen (Ilford, No. 2) was used, aperture *f*-8.

Mr. Lewis Medland entertained the meeting with many new zoological studies, shown by the limelight, other slides being contributed by Mr. Welford (seascapes and Thames scenery) and by Mr. J. S. Teape, who refreshed the memories of those who saw the Shrewsbury Convention with some pictures of the neighbouring country, which are some of the best that have come before the Association during the past year.

### PHOTOGRAPHIC CLUB.

DECEMBER 28, 1898.—Mr. Frank Haes in the chair.

Mr. I. ABRAHAMS delivered a lecture upon

#### JERUSALEM AND THE HOLY LAND.

accompanying his descriptive remarks with maps, plans, and photographs of the country, cities, and innumerable objects of genuine and doubtful authenticity of Biblical interest, which form the chief attraction to the tourist in these parts. From what Mr. Abrahams said as to the sanitary state alone of the places he visited in the course of his tour, it would appear that this Biblical interest need be very strong to induce a second visit; but, nevertheless, seen in London far from their originals, the pictures engaged the wrapt attention of an appreciative audience. Strange and rare were the two pictures of Jerusalem under snow, which concluded the display.

### FORTHCOMING EXHIBITIONS.

1899.	
January 25-31	Perthshire Society of Natural Science. C. F. S. Burrows, Hon. Secretary, 16, Princes-street, Perth.
" 30, 31	Southsea Amateur. F. J. Mortimer, Cornwall House, Ordnance-row, Portsea.
February 4-25	Edinburgh Photographic Society. Hon. Secretary, J. S. McCulloch, 2, George-street, Edinburgh.
" 13-18	Photographic Society of Ireland. Hon. Secretary, 35, Dawson-street, Dublin.
" 21-24	Hastings and St. Leonards. Exhibition Secretary, A. Brooker, 21a, Wellington-place, Hastings.
March 4-11	South London. Hon. Secretary, A. E. Allen, 27, Princess-square, Kennington Cross, S.E.

## Correspondence.

\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*\* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE ROYAL PHOTOGRAPHIC SOCIETY'S COUNCIL ELECTION.

#### To the EDITORS.

GENTLEMEN,—Your remarks *ex cathedra*, on the impending election of the Royal Photographic Society's Council are very suggestive reading to a meditative mind, more especially where they criticise the attitude of the professional man towards the Society.

When you suggest "an unofficial and unaggressive (*sic*) combination" of professional photographers to see "that their interests in the Society are not neglected," one has an uneasy impression that you have studied Machiavelli, "not wisely but too well." Looking over the names of those gentlemen constituting the Royal Photographic Society's Council for the year that has just elapsed, it does not seem to me that the professional man is very conspicuous by his absence. The Council as it stands seems a fairly catholic collection, for one finds the journalistic,

manufacturing, theoretical, portrait, and amateur phases all represented. Indeed, turning to the Council list for some ten years ago, one still finds it bearing a goodly number of professional names. The proceedings of the Society for the last two or three years contain papers on almost every branch of photography, and the photo-mechanical meetings most certainly seem specially designed to lure the professional worker to Hanover-square.

So far there seems no reason why the professional should combine even in the "unofficial and unaggressive way" you suggest. But what does "the typical professional photographer" expect of the Royal Photographic Society? Not long ago I was talking to one, and congratulated him on being an F.R.P.S., as duly set forth on all his mounts and show frames; he replied, very unenthusiastically, that it was so, but that it seemed to him a waste of money, as it didn't bring any more business to his studio! "Ab uno disce omnes!" This without doubt represents the frame of mind of the typical professional photographer towards the Royal Photographic Society, and to all such your advice to "combine in an unofficial and unaggressive way" is excellent; but, having done so, let them form a Worshipful Company of Photographers, who shall look after their financial and trade interests, because, as I understand the object of the Royal Photographic Society, the consideration of any commercial element would be wholly alien to its *raison-d'être*. For the life of me I can't see that the professional photographer should have any interests in the Royal Photographic Society apart from or beyond those of other members. I take it that, if a professional photographer is sufficiently interested in any paper read to join in the discussion, or has a paper sufficiently original to warrant its being brought before the Society, he has opportunities afforded him in common with other members of doing so. What more can he want?

His plaint of being unable to reach a seat on the Council is about as valid as his other complaints you mention. How can a man who neglects to associate himself with the best interests of a Society reasonably expect to share in the government of it? A seat on the Council of the Royal Photographic Society is, or should be, the reward it has to offer for interest and service shown in its well-being and advancement. The Photographic Society was not founded by professional men alone for professional men only, or to keep watch and ward over trade interests; indeed, at the anniversary meeting of the Society in February 1854, a motion was made to disqualify professional photographers from serving on the Council. The Society was, undoubtedly, formed for the advancement of photographic science, and its meetings for the discussion of photographic subjects; and, if the "typical professional photographer" finds that the Society's meetings "have no attraction for him," whose is the fault?—I am, yours, &c.

Tufnell Park, N.

G. T. HARRIS.

## TELE-PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—*Apropos* of your interesting paragraph on photo-telescopes with either concave or convex magnifiers (I used myself a combination of convex lenses, with a Newtonian reflector, some thirty years ago, to photograph a transit of Mercury, in, I think, November 1868), I would wish to remark on the special advantage which a combination of convex lenses may possess in correcting that *eccentric* dispersion of either primary or secondary spectrum (according as we use single or achromatic lenses), which might easily produce coloured margins, sensible to the eye on the focussing screen, upon the outer portions of an image produced by an ordinary tele-photo lens; for, though with the usual concave magnifiers this error is initially less than with convex lenses, yet with the latter it is perfectly corrigible by their due separation, whereas concave lenses can only be perfectly corrected by such a combination of Jena glasses as entirely to destroy any secondary spectrum by destroying irrationality. I think one of your correspondents complained lately of colour in the image of a tele-photo lens.

Requiring last summer a tele-photo combination of quite unusual power for some inaccessible architectural detail, I constructed one by combining two plano-convex achromatic lenses, apparently parts of portrait lenses, which I had by me, and with them magnifying the image produced by a large Ross portrait lens of about twenty-nine inches focus. The extemporised camera, with lenses, as I constructed it, varied in length from six to seven and a half feet, having equivalent foci of from sixteen to twenty-three feet. I send you a print from the first trial negative, exposed for three minutes, the equivalent focal length being then a little over seventeen feet, with a stop of one inch.

I am inclined to think the subject will bear description and investigation. Mr. Dallmeyer's lens was constructed for general requirements, and with a special view to compactness and speed, to which something must needs be sacrificed. Where, however, neither are of primary importance, immediate convenience and cheapness may sometimes be more easily combined with power and efficiency by a different construction. I contemplate several improvements, mainly for covering large plates, when I can find time. Meanwhile it may be worth while to note that, as in tele-photo combinations, only the central parts of the original image are employed; any good old lenses, of fine central definition though

small covering power, may be economically and very effectively utilised for this purpose.—I am, yours, &c.,  
W. H. WHEELER.  
106, High-street, Oxford.

## TRADE ENLARGERS.

To the Editors.

GENTLEMEN,—In last week's issue of the JOURNAL "Free Lance" devotes a paragraph to photographic enlargers' methods. May I be allowed to mention a case of mine by contrast?

In September last I received several negatives for enlargement to 18×16 inches. These were put in hand at once. As, however, the photographer was unknown to me, in accordance with my usual custom, a polite letter was sent with invoice, intimating that remittance would oblige, upon receipt of which the enlargement would be forwarded. To this I received no acknowledgment, and, although this gentleman has been written to several times, no reply has been vouchsafed, and, as I could hardly be expected to send goods indiscriminately to perfect strangers, both negatives and enlargements have lain on the shelf ever since.

Will "Free Lance" kindly make a suggestion in this case?—I am, yours, &c.,  
A PROVINCIAL ENLARGER.

To the Editors.

GENTLEMEN,—"Free Lance" is rather rough on poor trade enlargers. There are, no doubt, black sheep in every flock, and every enlarger may at times be compelled to keep his customer waiting a reasonable time.

I believe any one who knows about things will admit, if it were not for the trade enlargers, enlargements would not be where they are now.

With regard to free portraits, newspapers, &c., no one, I am certain, regrets those things more than the good and *bonâ-fide* enlargers, and any firm doing those should be found out, and left in the cold by professional photographers—"Boycotted."—I am, yours, &c.,  
R. W. HOWES.

Dereham, Norfolk, December 30, 1898.

## ALLEGED PORTRAIT OF CHRIST.

To the Editors.

GENTLEMEN,—As a pendant to your note on the alleged portrait of the Saviour, the enclosed description of "the best of men that e'er wore earth about him, the first true gentleman that ever breathed," may be of interest. It is copied from an original letter of Publius Lentulus, President of Judea, addressed to the Roman Senate, in the days of Tiberius Cæsar:—

"There appeared in these our days a man of great virtue, named Jesus Christ, who is yet living amongst us, and of the Gentiles is accepted for a Prophet of Truth, but His own disciples call Him the Son of God. He raiseth the dead and cureth all manner of diseases. A man of stature somewhat tall and comely, with a very reverend countenance, such as the beholder may both love and fear; His hair of the colour of a chestnut full ripe, plain to the ears, whence downward it is more orient and curling, and wavering about the shoulders. In the midst of His head is a seam or partition in His hair, after the manner of the Nazarites. His forehead plain and very delicate; His face without spot or wrinkle, beautified with a lovely red, His nose and mouth so formed that nothing can be reprehended; His beard thickish, in colour like His hair, not very long, but forked; His look innocent and mature; His eyes grey, clear, and quick. In reproving He is terrible; in admonishing, courteous and fair-spoken; pleasant in conversation, mixed with gravity. It cannot be remembered that any have seen Him laugh, but many have seen Him weep. In proportion of body most excellent, His hands and arms most delicate to behold; in speaking, very temperate, modest, and wise. A man, for his singular beauty, surpassing the children of men."

—I am, yours, &c.,

THOMAS R. BEAUFORT.

10, Victoria Tower-gardens, Millbank-street, Westminster.

## Patent News.

The following applications for Patents were made between December 19 and December 24, 1898:—

PHOTOGRAPH-HOLDER.—No. 26,837. "A New or Improved Device for Holding and Exhibiting Photos and suchlike." H. PRIMROSE.

CINEMATOPHONS.—No. 27,076. "Improvements in Winding Apparatus for use in Cinematographs or for other purposes where Films, Ribbons, or Strips have to be Unwound repeatedly in the same direction." H. EDMUNDS.

PHOTOGRAPHIC SIGNALLING.—No. 27,115. "A Lighting Material for Photographic Signalling and kindred purposes." Complete specification. Y. SCHWARTZ.

REPRODUCTION PROCESS.—No. 27,193. "An Improved Process of Reproducing Pictures, Photographs, Drawings, and the like." H. BIERENZ.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

RECEIVED.—E. M. S.; R. D. SMITH; A. EDGAR; W. B.; W. A. G.; W. WALKER. These and others in our next.

TADROUS HANNA.—In our next.

DISGUSTED.—Yes; from what we hear, we should say that the Cape offers a better field than Australia.

F. W. BEDFORD.—The *Stereoscopic Manual*, by Chadwick, price 1s., obtainable of any dealer, should answer your purpose. Messrs. Percy Lund & Co., Bradford, also publish a little book on the subject, price 6d.

Y. Z.—Better send us an example of the different kinds of pictures referred to, the coloured and the uncoloured. We shall then be better able to tell you how they were made, as all are not made in the same way.

BROMIDE PRINT.—S. Z. The Christmas card sent is not a platinotype, but an ordinary bromide print on matt paper. If you paid for platinotypes, you have been defrauded. There is no other term to use in such a case as this.

NOVITAS STRIPPING FILM.—M. J. JOHNSON says: "Would you please inform me where I can obtain the Novitas stripping film P.O.P., as described in THE BRITISH JOURNAL OF PHOTOGRAPHY for December 23?"—Of Mr. Otto Schozig, 31, Binfield-road, Clapham, S.W.

CARBON PRINTING.—BEDFORD. We know of no carbon tissue made on rough drawing paper. The carbon prints you have seen were made on the ordinary tissue of commerce, but transferred to the rough paper for development. There would be no advantage gained in making the tissue itself on the rough paper.

COPYRIGHT.—T. BIDGOOD. If the photograph is made copyright in England, there is no occasion to make it copyright in Germany. It is copyright there if it is made copyright here, in the same way that a photograph which is copyright in Germany is also copyright here, without registration being necessary in this country.

LANTERN.—T. BELL. The addition of camphor to the paraffin oil is said by some to improve the light and also avoid smell. With regard to the smell, there need be none without the camphor with a good lamp and well-trimmed wicks, provided the outside of the lamp and its fittings are kept scrupulously clean; that is essential.

FERROUS OXALATE.—H. B. Ferrous oxalate in crystal is an article of commerce, and may be had from such houses as Hopkins & Williams, Cross-street, Hatton-garden. It is a very inexpensive salt—about eighteen pence a pound, we think. We should advise you to purchase it instead of troubling to make it, and it is some trouble to make.

PLATINOTYPE.—ARCH. STUART asks: "Would you kindly tell me in your JOURNAL if there is any residue to be obtained from the hydro. acid after the platinotypes have been fixed in it; and, if so, would you tell me what is best to use to throw it down?"—There is no platinum in the acid that would be worth even the slightest trouble of collecting.

COLLODIO-CHLORIDE.—S. COLEMAN. Some of the surfaced papers, as used for lithographic purposes, will answer for coating with collodio-chloride of silver; but it is far better to employ paper specially prepared for the purpose—baryta paper. This may be obtained from Otto Koenig & Co., Cross-street, E.C.; but whether they supply it in small quantities or not we are unable to say.

PATENT.—INVENTOR. You can certainly patent the apparatus, as you can anything else in this country, but we may tell you the patent would not be valid. Similar apparatus, if not identical, has frequently been described in the JOURNAL when photography was comparatively young. However, patents for old inventions are often made profitable, if they are not contested, such is our patent law.

BROKEN NEGATIVE.—C. A. B. It is, as you say, vexing to have a negative broken when it is sent to be printed from, but accidents do happen, you know. We do not expect you will get heavy damages, or any damages at all. As a rule, printers and enlargers notify on their lists that they will not be responsible for negatives sent to them. Nor could they be, as in most cases of breakage in printing it is the fault of the glass.

PICTURES IN SPACE.—SPIRIT asks: "What apparatus is required for projecting pictures in space without screens, and to bring objects near audience in hall, such as I have seen at Egyptian Hall? Are there books on above subjects?"—We cannot profess to explain how the conjuring is done at the Egyptian Hall. An apparatus, however, for projecting images in space was shown at one of the Royal Photographic Society's exhibitions two or three years ago. It consisted of a broad white bath, pivoted in the centre, which is made to revolve so rapidly that it seems invisible. On this the image is projected by the lantern, when it appears as if in space.

HYDROQUINONE DEVELOPER.—A. U. ENDACOTT asks: "Will you kindly give me a recipe for a hydroquinone one-solution developer? I have looked through the ALMANAC, but am unable to find anything but the metol and hydroquinone; but a brother in the profession has it, but will not give me the formula. If you could favour me with same, you would greatly oblige."—Simply omit the metol and double the proportion of hydroquinone. Other proportions of the hydroquinone may be used.

STAINED PRINTS.—WINDSOR asks: "Can you tell me what is the cause of the yellow marks on the enclosed prints?"—We cannot say definitely, except that they are due to faulty manipulation, and of that there is no doubt. By merely looking at a few prints, with no data to form an opinion upon, it is impossible to say the precise cause. Insufficient fixing, too weak a bath, prints allowed to stick together while in it, air bubbles adhering to the prints while in the solution, &c., will cause stains and spots similar to those on the prints sent. Had we seen the prints produced, we should know the cause.

CINEMATOGRAF ENTERTAINMENTS.—SHOWMAN writes: "The new regulations issued by the County Council are putting my business quite out of my hands. Can you kindly give me any tip by which I can get round them, as it is getting a serious matter with me?"—We certainly cannot, for the regulations, as made by the Council and the insurance companies, must be complied with; and the proprietors of places licensed by them will, in their own interests, see that they are abided by. The regulations, as issued, are irksome to many; but the numerous weekly accidents, in incompetent hands, tend to show that there is good reason for them.

PENCIL STAINS ON PRINTS.—J. E. HUNT asks: "Could you inform me if it is possible to remove copying-ink pencil marks on silver prints? I had a number of prints to mount, and each print was numbered and marked with copying ink on back, and the impression from the back now appears on the front. Is there a method of removing the stains? If so, I should feel greatly indebted for same."—We do not expect that the stains can be removed; but, as we do not know the composition of the copying pencil, we cannot say for certain. In all probability, if the stains could be taken out, the remedy would be worse than the disease, as the print itself would suffer by the treatment.

STAINED CLOTHES.—J. COWLEY writes: "I would feel much obliged if you could give me your opinion in Answers to Correspondents of the following: Some days ago I was unfortunate enough to spill a bottle of hydrochloric acid on my trousers, which, of course, immediately became red, and, as red and black pants do not alter their come up to my idea of taste, I should like to know if the stain can be removed, or if they can be dyed, which I greatly doubt. Thanking you in anticipation."—Unless treatment of the stains with ammonia will remove them, the only suggestion we can make is to put the garment in the hands of the dyer, unless, indeed, the fabric itself is damaged. Had ammonia been applied at the time, it is probable that no injury would have resulted.

OPALINES.—PLUSH says: "I should feel obliged if you would answer the following questions in your next issue: 1. What kind of printing paper is the best to use for mounting on glass in opaline form? 2. How is the mounting done? If gelatine be used, should it be any special kind? I have used Ilford P.O.P., but sometimes this does not adhere well at the edges, and when dry it sometimes peels off. Can you give me a remedy to prevent this? 3. Can you give me the address of any actual manufacturers of plush mounts and boxes? I am told that German firms turn these out the cheapest. Your opinion will be much esteemed."—1. Either albumenised or gelatine-chloride. 2. See page 927 of the ALMANAC. The gelatine should be free from acid and colourless. Nelson's No. 2 solution is a very suitable kind for the work. 3. We do not know of any German manufacturers of the mounts. The mounts are supplied by Marion & Co., and similar firms.

GUM BICHROMATE.—GAMMA writes: "I have been reading the interesting article in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1899 on the gum bichromate process, and, as there are two points which are not quite clear to my mind, I shall be glad if you will kindly reply to the following: 1. After sensitising and drying the papers, must the coating with pigment and subsequent drying be done in yellow light, or could the coating be done in daylight? 2. When exposing the paper, please explain more fully the purpose of employing and mode of using a strip of the actual paper you are printing upon as an indicating medium? 3. Would this paper be suitable for first experiments?"—In reply: 1. Yes, in the dark. 2. Simply expose the strip of paper in the actinometer, as directed, until it gets to the tint desired—three, four, or more tints, according to the density of the negative. It is a guide to exposure only. 3. Certainly.

COLLODIO-CHLORIDE.—GOLD AND PLATINUM says: "I should be much obliged if you would give me your valuable opinion with respect to the enclosed collodio-chloride P.O.P. combined toning gold and platinum: 1. I have had the paper some time. I should like to know if it is in good condition yet. Enclosed is a sample unprinted, and one printed (untoned). 2. As I did not receive a formula with the paper, I used the one on page 891 of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, with the enclosed result. I have other formulae, in which the gold baths are almost identical in each case, but in the platinum formulae there is a difference ranging from one ounce to fifteen minims phosphoric per grain chloride of platinum. If you could give me any hints, I should feel obliged."—The paper has become quite spoilt by the long keeping. It is yellow and spotty, and the spots are very pronounced where the paper is looked through. It would be useless to try to get good prints on the paper, whatever bath be used. The toning bath referred to in the ALMANAC of last year is by Dr. Lamer, and is quite right.

## EX CATHEDRÂ.

WHAT may reasonably be regarded as a small revolution in photographic printing methods appears to us to be in course of progress amongst professional as well as amateur photographers just now. This is being effected by means of the process of printing known as Velox. Some two and a half or three years ago, when this highly convenient method of printing was being brought to the notice of our American brethren by the Nepera Company, of New York, we perceived that its advantages in practice were so great, and the qualities of the results that were then shown were so distinctively fine, that we were sure British photographers would not be slow to avail themselves of the manifest convenience of the process when opportunity offered; and the result shows that we did not err in our confidence. Velox has deservedly taken its place, in a short space of time, amongst recognised modern photographic printing processes.

We are not penning these lines for the express purpose of advantaging, in the estimation of our readers, the Velox process *per se*—the excellence of the results produced on the

various Velox papers is too well known to need insistence upon here—but rather of drawing attention to the valuable principles upon which, in practice, that process relies. Eighteen or twenty years ago, when paper, coated with a washed gelatin-bromide emulsion, was being introduced, such were the then prevalent ideas on the subject that the practicability of a paper having the same characteristics as Velox would, no doubt, have been generally scouted. The high sensitiveness of gelatine emulsions was only then beginning to appeal to the imaginations of most photographers, and to tell them, in those days, that it would have been quite easy to prepare an emulsion paper which could be safely handled in gaslight or diffused natural light, exposed in contact with a negative for a minute or two, and that an unfogged, rich, velvety-black image could be fully developed up in half a dozen seconds by means of a brush charged with alkaline developer, would surely have elicited expressions of scepticism and incredulity. Yet such a process is before photographers at the present moment.

\* \* \*

FROM personal trial of this plan of printing we can speak in praise of its simplicity and qualitative attractions. We observe that many professional photographers—a class notoriously slow to exchange old ideas for new ones—are adopting it. We shall be surprised if the process does not secure a great run. Note that we are indebted for its introduction to our American friend, but we put it to the leading British sensitive-paper makers that there is a vast field open for a surface of this kind—a slow emulsion, manipulatable in actinic light, requiring a comparatively short exposure, developing very rapidly, non-fogging, and yielding rich and varied results. Such a process, it seems to us, creates a place for itself between the ordinary print-out methods and the very rapid bromide development processes. We commend the hint here given to the home manufacturers.

\* \* \*

THE author of the sensation story at present appearing in the *Daily Mail* falls back upon the device, not by any means for the first time utilised, of selecting his characters from living persons, whom he introduces by their own names. He also places photography under tribute, not, however, with the most conspicuously happy results. Here is an extract from a recent chapter: "The advantage that would accrue from some secret

means of photographing instantaneously documents not possible to carry away set him thinking, with the result that he produced a curious and ingenious camera. It was just an ordinary top hat. In the centre of the crown was a small hole, apparently a ventilator, but in reality the small right-angle lens of an instantaneous camera, every wheel and screw of which he made with his own hands. It was devised upon the most ingenious plan. The shutter of the camera could be operated from the brim of the hat. The interior of the *chapeau* was heavily decorated, after the manner of French hats, much pleated and puckered, so as to create, as it were, a false crown, in which he concealed the small metal camera. This had a roll film, and the shutter, once adjusted, could be liberated by pressing a spring connected with a wire to a flat cardboard button, let into the hat brim so artfully as only to be discernible upon the closest scrutiny. This button was located in the front of the brim, just where the thumb might come when taking the hat from the head."

\* \* \*

If we remember aright, Messrs. Adams & Co., of Charing Cross-road, W.C., introduced some years ago a hat camera, but we do not think it was claimed to contain a "right-angle lens of an instantaneous camera," with "wheels" as well as screws. The author, like most novelists who make use of photography, has done so somewhat weakly, it is true, but he has the satisfaction of knowing that he has made his photographic readers smile. It is not every modern novelist who is so successful in that respect. This particular writer lets his character take instantaneous pictures of documents in rooms, &c., but candidly owns that there were fifty per cent. of failures. The liberality of the percentage leaves us not altogether hopeless that the author will one day write learnedly of photography.

\* \* \*

MESSRS. WELLINGTON & WARD, of Elstree, inform us that the continued growth of their business necessitates a further addition to their manufacturing and office premises. They have in hand the preparation of a new flexible support for sensitive emulsions, which will probably be placed on the market in the course of the present year. From the description given us of the manner in which the support will require manipulation, it appears to possess the elements of both novelty and simplicity. We congratulate Messrs. Wellington & Ward on their progress and enterprise, due in large measure, of course, to the fine artistic appreciation and great technical knowledge of which Mr. Wellington is so widely known to be the possessor. Readers of our advertisement pages will have noticed the strikingly effective designs of Messrs. Wellington & Ward's announcements. It will be seen that, at present, their artist has laid a bold hand upon the signs of the zodiac, Capricornus (the Goat) being shown as keenly interested in the science of contact printing from the negative. Aries, Taurus, Gemini, and the remainder of the series will appear in the course of the year. There is wide scope for the introduction of effective designs into commercial announcements, and such departures as that of Messrs. Wellington & Ward deserve encouragement.

\* \* \*

A SPECIAL general meeting of the Pharmaceutical Society of Great Britain was summoned for Wednesday last, to consider a proposal that certain recommendations, framed by the Society

so long ago as 1871, with the view of securing greater safety in regard to the storing, dispensing, and sale of poisons, should be now adopted as compulsory statutory regulations, in accordance with Section 1 of the Pharmacy Act of 1868. From and after the affirmation of the proposal nothing would be required but the formal sanction of the Privy Council to give the regulations the full force of law, with a maximum penalty of 5*l.* for the violation of any one of them. The proposed regulations provide for the securing, labelling, and marking of the special vessels in which poisons are kept, and that the vessel sold shall be distinguishable by touch as well as properly labelled.

\* \* \*

WE have already drawn attention to the fact that, in May next, the Società Fotografica Italiana will hold an International Photographic Exhibition in celebration of the tenth year of the Society's existence. There are to be ten classes for exhibits of historical, artistic, mechanical, photo-material, photo-mechanical, optical, scientific, and industrial interest. According to the prospectus the Exhibition is being planned on a large and comprehensive scale. The Exhibition, which is under the patronage of the Prince of Naples, will have the advantage of the assistance of the Municipality of Florence and a Committee of which the well-known experimentalist, Colonel Pizzighelli, is a member.

\* \* \*

A FEATURE of the Exhibition will be a special Invitation Section of British photography. In this it is desired to illustrate more particularly what has been achieved by the principal exponents of modern pictorial photography in Great Britain, and to that end special invitations to contribute examples of their work have been addressed to the most prominent exhibitors. We are informed that Italian photographers have yet to learn to what a pitch of artistic excellence modern pictorial photography has been brought by British photographers, and it is therefore to be hoped that a unanimous response will be given to the invitations that have been issued. It will be seen, from a letter in our Correspondence columns this week, that Mr. Henry E. Davis, of the Camera Club, has the work of the Invitation Section in hand, and to him inquiries may be addressed. We wish Mr. Davis the utmost success in his efforts to secure a thoroughly representative collection of British work for such an important Exhibition as that at Florence promises to be.

\* \* \*

It has been decided that the Yorkshire Photographic Exhibition at Bradford shall remain open till January 31. The attendance up to the 9th inst. reached the very fine total of 93,000. The number of pictures sold is fifty-five, of the value of £83. We congratulate all concerned in the organization of the Exhibition on the very great success it has met with.

\* \* \*

It is not often that men of science nowadays openly oppose the substitution of the metric system for English weights and measures, but Professor Sweet, in an American contemporary, is courageous enough to do so. In his opinion, allowing that all the advantages claimed for a universal system exist, it would be much easier for the nations now using the metric system to change to the better English one, as they will in time to the English language, because half of them already

have the English measures, using them still to a considerable extent, and the change, if worth while at all, would be easier. Why the nations who had no standard of their own adopted the metric system in place of the English was because it was settled by the men who use the pencil rather than those who do the weighing and measuring.

\* \* \*

He adds that, as evidence that the manufacturers in his country (America) do not favour it, letters of inquiry were sent out to about seventy of the leading manufacturers, and, of over forty replies received, only three favoured it, one or two allowed that they would adopt it when compelled, and the rest were utterly opposed to it and would not adopt it, and yet nearly all these manufacturers are doing a large foreign trade. "The cost affects all industries, from the few dollars of the farmer to the tens of thousands of the manufacturers; and what, he asks, will it save? A lot of figuring claimed by its advocates! While, as a matter of fact, for a time in many cases the figuring will be multiplied tenfold. All drawings will have to be made anew or refigured, all tables changed, the engineers' private notes translated, all the constants in formulae will be wrong, records for estimates will have to be corrected, and, worst of all, every book now printed in the English language, where reference is made to weights and measures, will need to be translated by posterity before they can get a realising sense of the magnitude of the thing mentioned."

\* \* \*

In striking contrast to this unfavourable opinion of the proposed change is the announcement recently published on behalf of the Decimal Association which has taken a leading part in educating public opinion, and in making known the advantages of the metric system in this country. It is pointed out that the strongest argument in favour of metric weights and measures is the fact that nearly all the leading civilised countries of the world, as well as nearly all our competitors in foreign trade, use them exclusively. From a table given in a pamphlet published by the Association it appears that the countries which have already adopted the metric weights and measures represent a population of over 448 millions. Our Consuls have almost unanimously reported in favour of the system; our chief Chambers of Commerce have passed resolutions in favour of it; in the new "British Pharmacopœia" the use of the system has been much extended, and numerous trade associations have given support to it, while in no single case has any body of wholesale or retail traders opposed its compulsory adoption. It is now especially urgent that an Act should be passed to make the change compulsory, and all who are interested in this important question are urged to become members of the Decimal Association, and to give it the benefit of their influence and co-operation. The Secretary is Mr. Edward Johnson, Botolph House, Eastcheap, London, E.C. Possibly Mr. Johnson may think fit to see that Professor Sweet has a copy of the pamphlet.

#### WINTER PHOTOGRAPHY.

LAST week we gave some practical hints as to how many of the inconveniences often experienced during a hard and prolonged winter might be avoided if a few simple precautions were taken beforehand. Up to the present, however, we have had no real winter, for the weather has been abnormally mild for

the season, although a long and hard one was predicted last autumn by some of the weather-wise. There is, however, plenty of time yet; for it is noteworthy that the "good old-fashioned winter" of 1895, which lasted six or seven weeks with great severity, did not set in till later than this, also that it was preceded by a long spell of exceptionally mild weather. Such may be the case this year—who knows?

Professional photographers must, necessarily, suffer some inconvenience from a long and severe winter; but they, at the same time, may often turn it to profitable account, and some have done so in the past, though their number is not large. In Canada, America, and in Russia, winter portraiture is made a profitable feature of. Outdoor backgrounds of snow-clad scenery, accessories, &c., are to be found in most of the studios there, but they are seldom seen in this country, perhaps for the reason that we seldom get a long winter, or, maybe, English portraitists are not so enterprising as their *confrères* across the herring pond; possibly also because portraits with winter surroundings might be thought out of place if we have no frost or snow. It by no means follows, however, that there should be a long period of snow to make winter portraiture profitable. A week of frost and snow will suffice, as many portraits may be required afterwards, as winter costumes are in vogue for months, and there are no more applicable backgrounds for fur-clad figures than those representing wintry aspects, instead of those one too frequently sees used, sunny summer ones. Heavily or fur-draped sitters, before a bright, sunny summer background, always strikes one as being not a little incongruous.

Portraits as Christmas and New-year's cards have become pretty general during the past year or two, but they would often be more in keeping if they were taken under seasonable aspects—winter costumes and wintry surroundings. Most of the pictorial chromo-lithographic cards are representative of winter, in some form or other; why, then, not photographic ones?

We have, before now, pointed out how easily any one, even unacquainted with drawing, can quickly convert any old disused scenic background into a suitable one for the present purpose, simply by emphasising the sunlit parts with white paint, distemper, or even with a piece of chalk, and any other points upon which snow might be supposed to settle; also how winter effects can be further represented in the studio by covering the tops of outside accessories with cotton-wool, which makes a capital representation of a thick coating of snow upon them. A few sheets of drapers' wadding spread upon the floor will convey the idea of a thick fall of snow, and thus complete the arrangement of a really congruous winter scene.

Falling snow in the picture is well imitated by slightly splashing or spraying the negative over with an opaque pigment. The tube water colours, diluted with thin gum water, is an excellent medium for the purpose. If the sitter be taken holding up an umbrella, whitened on the outside or covered with thin wadding, the "snow" may be wiped away from the face, and thus, while the features are clear, there will not be the incongruity always noticed in such pictures, where the snow is shown falling thickly everywhere except just before the face. If we have any real winter this year, the foregoing hint may be of service to many portraitists by reminding them that winter, with all its inconveniences, may be turned to account by bringing additional grist to the mill.

Turning from the professional to the amateur element of

winter photography. Up to the time of writing, the amateur has had, at least in the metropolitan districts, but little opportunity of obtaining winter pictures, but is he ready to take them as soon as an opportunity may occur? In the fickle climate of this country we may have a heavy fall of snow at an hour's notice, but, with a sudden change in the temperature, all trace of it may be gone in a few hours; therefore the opportunity, which may not occur for another year or more, should be seized at once. Although we may have no snow this winter, there is little doubt but that we shall have plenty of hoar frosts in the morning, even in the spring, and these make excellent food for the camera, particularly for lantern slides. The best hoar-frost effects do not last long—only for a very few minutes sometimes—for, if the sun puts in an appearance, they quickly disappear. But, while the sun is shining, the particles glisten like diamonds, and that is one of the greatest charms of hoar-frost pictures, especially in the lantern.

To get the best frost or snow effects, backed plates are imperative. Seeing that the best of this class of subject has generally to be taken at short notice, and frequently without time for special preparation to be made, we ask if all amateurs who desire to secure such subjects are fully ready to secure them immediately the opportunity occurs, and thereby obtain what they may not have the chance of doing again till perhaps next winter.

**A New Element—Powerful Emitter of Actinic Rays.**—Since Röntgen's wonderful discovery various investigators have been at work studying the properties of radiatives of somewhat similar properties from various unelectrified bodies. M. Le Bon's "dark light" and M. Becquerel's experiments with uranium and its salts are cases in point. Recently we gave an account of the discovery of a new element, extracted from native oxide of uranium (pitchblende), to which the name of polonium was given, which possessed a radiating power far greater than uranium. Mons. and Madame Curie, the discoverers of polonium, have, in conjunction with M. E. G. Bémont, been making further investigations on the same lines, and have succeeded in extracting what they believe to be another new element, the chlorine salt of which possesses a radioactive power of extraordinary activity, 900 times that of uranium. But, even at this point, the experimenters named believe that their newly discovered element, which they term radium, is only extracted in a very impure state, and that, if they can succeed in isolating it, its activity will be enormous. Its physical properties very closely resemble those of barium, as does its behaviour in the spectroscope, with the exception that radium shows one unknown and unnamed line. As to the specific action of the rays, they will render potassium platino-cyanide fluorescent through a thin sheet of aluminium, and in half a minute will have as much action on a dry plate as uranium will in several hours. The authors conclude their paper by saying, "We thus realise a source of light, very faint, it is true, but functioning without a source of energy. In other words, this is very like a case of "perpetual motion."

**Röntgen Rays in Therapeutics.**—The action of the rays in producing dermatitis, an acute inflammation of the skin, became known at an early stage of the experimenting they were subjected to, but for a while their properties in this direction were not investigated. At present, however, they promise to be as useful in medicine as in surgery in connexion with the photographic plate. So far as regards the injurious action on the skin, Dr. Schiff, in a communication to the Vienna Medical Society, points out that no harm accrues if the radiation be not too strong, or if, when strong, it be not permitted to act for too long a time, till hyperæmia or excessive determination of blood to the skin. He narrates his experience in the case of the most intractable disease, lupus, one form of which

he had been able to cure; and, indeed, he brought his patient to the meeting of the Society, and showed that, after two months, there had been no return of the malady.

**Ten Million Diameters' Enlargement.**—Dr. Elmer Gates, of Washington, invented a new form of microscope, and published a description of it some eighteen months ago, by means of which he claims to be able to obtain photo-micrographs with objectives of comparatively low-power enlargements on a scale hitherto undreamt of. When his discovery was first published, it was treated with derision, but he appears to have been steadily working in the same direction, and has formed a syndicate to produce the new microscope, which, he states, performs the marvellous feat of amplifying the image to the extent of 10,000,000 diameters. He terms his instrument the double microscope, and in a recent number of the *American Journal of Microscopy*, has a long descriptive article of his invention, which, at the outset, seems simple enough. It is, in fact, simply an arrangement of two microscopes, placed one behind the other. A comparatively low power is employed with the instrument nearest the object to be photographed, and, its eyepiece being removed, a second instrument is employed to magnify the image, the objective of the second microscope being placed in the focal plane of the first, taking the place, in fact, of an eyepiece. Taking a one-sixth of an inch objective for the first, and a two-thirds of an inch for the second, Professor Gates claims to have obtained a magnification greater than would have been obtained with a one-sixteenth of an inch as ordinarily employed, with details beyond what a one-twenty-fourth would give. He claims to have demonstrated that his principle of magnifying the image gives far better results than obtaining the same degree of magnification by the use of high-power objectives. Naturally an immense amount of light has to be employed when the area of the image is so great compared with the minute aperture the available light has in the first instance to pass through. Professor Gates has one method of obviating this difficulty, which consists in using a powerful electric light, but allowing only the more refrangible rays to pass through the objective, and so avoid burning up the object or the objective. The microscope he is now engaged in constructing is built with his special monochromatic illumination as the leading idea. His experiments, so far, have been with a twelve-inch heliostat, the rays from which are condensed to less than one-hundredth of their diameter, then rendered parallel and passed through the microscope after being filtered from the heating portion of the spectrum. It would be premature to criticise the instrument in its present stage; we can only say we await developments.

**Eclipse Observations.**—The interest taken in the solar eclipse of last January is well shown by the facts published by the Meteorological Department of the Government of India, that no less than 158 observers took part in the observations which are being tabulated and reduced, and which, it is expected, will be printed during the course of the year.

## DEVELOPMENT, INTENSIFICATION AND FIXING, IN ONE OPERATION.

### II.

So far, the best results have undoubtedly been obtained with pyro-ammonia, possibly because more attention has been given to this method than to any other, though hydroquinone and soda, and ortol ammonia seem to promise well. One element in favour of pyro-ammonia is the almost unlimited power it gives of modifying the reducing action, a power which can be pushed or utilised to a far greater extent in physical than in merely chemical development. In fact, it would seem that the full value of the Wellington method of development or intensification can only be secured when the alkali is used in the caustic state or in a very concentrated form. When carbonate of soda is employed, there is comparatively little opportunity of varying the reducing power of the solution, and it is for that reason that ortol ammonia has been used for gelatine plates.

instead of ortol with carbonate of soda or potash, in order to secure the advantages of physical intensification with the minimum of pyro stain.

The reducing solution consists of the ordinary ten per cent. pyro, with a similar proportion of metabisulphite of potash, or 1 ounce each of pyro and metabisulphite made up to 9 ounces of stock solution. This can either be used from a dropping bottle, or may be diluted with 15 volumes of water for actual use, 1 drachm being made up to 2 ounces of developer. It is more convenient, however, to use the whole of the solution by means of dropping tubes, as they are then equally ready for either gelatine or collodion. Another formula which works well, and contains sulphite of soda in place of the metabisulphite, consists of pyro 1 ounce, sulphite 4 ounces, with 60 grains of citric acid, the whole made up to 9 ounces as before. The citric acid is intended to slow development in order that it may be arrested at the proper moment, when a long exposure has been given to the production of warm tones.

The other developing solutions consist of the usual ten per cent. bromide and liquid ammonia—one in eight—the latter strength being chosen as the most convenient for collodion plates while equally applicable to gelatine if desired; in fact, I use the same solution indiscriminately for both gelatine and collodion, the formula being practically the old "ten per cent. solution."

But the most important item in the combination is the intensifying solution, for which I use substantially Mr. Wellington's formula, but in a more concentrated condition and with the proportions a little varied. I have given several months' attention to the working of this with a view of discovering the functions of the various ingredients, with the result that it now works with a degree of certainty and satisfaction that I had not hitherto met with.

Briefly, the principle upon which the solution works appears to be this, that the solution of silver should be in a state of what has been called "unstable equilibrium," ready on the slightest inducement to throw down some of its metal in one form or other. The silver solution itself should be in such a state of concentration that, when added to water in the proportions in which it is used in the developer, it will *barely* retain its contents without precipitation. It may indeed be of such strength that added in this manner a precipitate is caused, but this, though not otherwise objectionable, gives rise to a muddy solution during intensification. When in this delicately balanced state and under the influence of the reducing agent, the silver is deposited with great rapidity, and at the same time with perfect regularity, and, as I shall show, the progress of the operation can be modified to almost any desired extent.

The precise composition of the silver solution does not matter except so far as it affects convenience. Almost any combination of silver with hypo, sulphocyanides or cyanides, sulphites or other solvents, can be used for intensifying, though it is only when the conditions laid down above are observed that a practically useful solution is obtained. Mr. Howard Farmer's original solution of bromide of silver in hypo was objectionable for these reasons, namely, that owing to the strong solvent action of the hypo it was absolutely necessary to use it fully saturated with silver, and in that condition, in the presence of the reducing agent, the precipitation took place too rapidly; there was no regularity or certainty that intensification took place at all, though an unnecessarily large quantity of silver was thrown down somewhere, principally on the sides of the dish.

The introduction of sulphocyanide of ammonium by Mr. Wellington changed the state of affairs completely; and I think it will be found that the very quality that unfits sulphocyanide for fixing purposes makes it useful for this. It differs from hypo and cyanide in its solvent powers in this, that it dissolves an increasingly larger proportion of silver salts as its own strength is increased, whereas with the other two the stronger the solution the smaller the relative proportion of silver taken up. The immediate result of this is, that whereas, on diluting a saturated solution of silver in sulphocyanide of ammonia, no matter to what extent, a *precipitate of silver salt* will take place; but, under the same circumstances, hypo solution, when diluted, will *take up more* of the silver salt. Hence, if a saturated solution of hypo be prepared for use, the very act of adding

it to the developer, by dilution restores some of its fixing power, and consequently it attacks the film of bromide of silver. Incidentally, it may be mentioned, too, that this explains why a negative that is slow in fixing may be hastened by taking it from the fixing bath and washing it. The pores of the gelatine being full up of saturated hypo, the fixing is stopped; but, when the hypo is diluted by washing, its fixing action reasserts itself.

Although the solution may be formed by dissolving bromide or chloride of silver, for the purpose of securing the greatest amount of control it is preferable to use nitrate of silver, as the sulphocyanide of silver then formed is more soluble than the haloids, and, further than this, is convertible into the haloid condition in the solution, which gives a further power of modifying the action. For instance, the addition of a drop or two of bromide solution, by converting a portion of the sulphocyanide of silver into the less soluble bromide, brings the silver into a more precipitable state, and thus hastens the action. Theoretically a soluble chloride should act still more energetically, since chloride of silver is less soluble in sulphocyanide than the bromide; but here the contrary, or greater soluble power of the hypo, comes in to neutralise it. Iodide of potassium, or other soluble iodide, exercises the strongest action in this direction.

W. B. BOLTON.

#### THE PACKING OF PLATES.

How well I remember my first box of dry plates, somewhere back in the "seventies," and how they were packed in a thin wooden box, with nailed lid. The variety in methods of putting up dry plates at the present day is wide, and, as in my speed-testing work I have to open boxes of every brand sold in England, I am tempted to give my impressions on this minor question, in the hope that it may lead to reform in one or two directions. If I write in a fault-finding strain, let me offer one consolation to our plate-making friends, who have lately turned out such good wares, that there is little room for a grumble at the quality of the films, and one can only criticise such points as packing, designation, and speed-marking.

First of all, oh, ye of the Paget Company, why are the *x's* on the labels of your boxes so ingeniously located that they cover the end of the box which has to be opened, and are always torn off in consequence? An unfortunate possessor of one opened box each of xxx and xxxxx is a lost man if he did not remember to pencil these brew-house symbols on the boxes when he opened them. It is true that there is a slight difference between the colour of the labels, but can a weak mortal be expected to remember that so many *x's* belong to a blue-grey, and so many to a grey blue?

A few years ago a number of makers put their plates in perfectly plain boxes, the name and other information being on an outside wrapper, which had to be torn off to get at the plates. Any identification was therefore destroyed when the box was opened. The Warwick Company, who are now almost alone in this plan, have brought it still further to perfection, so that, when you have torn off the wrapper, you have a perfectly plain black box on which you cannot even write the magic word "Warwick" with a black lead.

The Paget Company also adopt a nameless box with outer wrapper for their Phoenix plates.

What a difference to the methods of the Ilford people, who put the label bearing the name of the plate on the lid of the box as well as on the outer wrapper, and, as a further precaution (in case of lids getting changed), put the plate name on the bottom of the box.

The Barnet firm also indicate the different brands by initials on the bottom of the box, but I do not remember any one else adopting this plan. The four firms who mark each package with their Hurter & Driffield speed numbers do so on the outer wrapper only, and, as this has to be torn away to get at the plates, the information is lost unless one remembers to pencil it on the box-lid. Surely there is room for improvement here.

In the case of the Gem Company, the distinguishing name of the brand is also sacrificed when the outer wrapper is torn off, and the different speeds "Universal" or "Meteor" are only distinguished on the boxes by different coloured labels.

One is not likely to forget the opening of a box of the dear old Wratten plates; first a string has to be cut to take off the lid, within is a sealed package which again requires the aid of a penknife, then

wrapper after wrapper of different kinds of paper, there being five in all, before the plates are reached. Contrast this with the simple wrapping of four plates in one piece of paper only as adopted by most makers now. I have never found the simpler plan endanger the plates.

I doubt if the plan of wrapping up plates in "waxed" (paraffin) paper has any real value.

Such paper is not really waterproof. It is true that damp air can be kept out by this means for a few hours, but not for days.

The methods of packing the plates inside the box are of interest. The strips of paper put between the ends to keep the plates apart often cause markings, although not of a serious nature, being close to the edge. I have not noticed that the use of corrugated paper (B. J. Edwards) leads to markings, but with this plan, there being no wrapper of paper on the plates, a double lid has to be provided for the box.

For convenience of use, four plates in a wrapper simply laid in a box with flat lid is hard to beat.

Personally I do not like the boxes with slide in lids, where the plates are drawn out at end of box, it being difficult to replace one of the parcels when opened to take out one of the plates.

The plan (invented, I think, by Mr. Cowan) of folding plates face to face, being left joined by an unbroken hinge of film, seems to answer its purpose; I must, however, record the fact that, in the case of Thomas's lantern plates packed on this plan, I have spoilt many plates by treating two extra thin ones adhering together as if they were one, and this even when I was doing my best to avoid such an error.

The colour of the label on a box is of importance for use in a dark room, and the name of the plate should also be in large, plain letters, or it will be impossible to read.

Messrs. Fitch put up their excellent films in blue envelopes. Every dark-room light is especially designed to cut off all blue light, and consequently the Fitch packages reflect no light in the dark room, and are absolutely black. The printing on these blue wrappers is therefore invisible in the dark-room light.

And why, Messrs. Fitch, when you list your films as Ordinary, Rapid, and Special Extra Rapid, should you not also print these names on the packages? The labels only tell us of sensitometer 20, or 25, or 30, as the case may be, and, as these numbers are not mentioned in your list, you set us a puzzle each time we pick up a package of your films.

Probably either yellow, or orange, or white is the best colour for labels to read in the dark room, and it is a mistake to attempt to distinguish between different brands of plates by the colour of the label only, as dark-room light upsets this.

A variation in colour for each different brand of one maker's plates is a useful distinction, especially on a dealer's shelf, but in my opinion it is far more important to print the distinguishing name in large letters on the label pasted on the top of the box.

Another bone to pick; this time with the Ilford Company. Their plan of wrapping up cut sizes of P.O.P. in shaped paper with flaps to fold over is excellent for that purpose. But it is a mistake to apply it to the package of films; there are minute pinholes at the corners of the packages through which the light can come, and, after the outer envelope is opened, the package is unsafe.

There is one immense improvement in connexion with the marking of packages which will probably not be adopted until users of plates insist upon their interests being considered before that of the dealers. I allude to the importance of marking each box of rapid plates or films with the date of manufacture.

It is a well-known fact, acknowledged by the best makers, that fast plates do not, as a rule, keep well, and cannot be relied upon to give clear, vigorous negatives after six or nine months from date of manufacture. It is not to the user's advantage to have plates more than six months old, but it is not to the dealer's advantage to declare the age of plates, in case he should be left with an unsaleable stock on hand. It is here that the difficulty lies, and I feel sure that makers would willingly mark each box with the date of manufacture if dealers did not strongly object to such a course. In the mean time knowing photographers do not go to dealers for fast plates, but go direct to the makers, in the case of films the Eastman Company have boldly "taken the bull by the horns," and mark each package with the intimation that it must be used up before a named date, the date being some eight months or so after manufacture. It is some satisfaction to me, and a proof that calling attention to these matters is not without result, that the Eastman Company, in making this change some years ago, quoted my published opinion that even the best of films will not keep good for long. The Blair Company have also adopted the same plan.

If makers would unite together to mark date on boxes of plates, the difficulty would be solved.

In my speed-testing work I find it absolutely necessary to mark each box with date of purchase, as the nearest approximation to the desired information.

ALFRED WATKINS.

### THE KROMSKOP.

It was pleasant to hear the genial New-year's greetings of the members of the Camera Club when they met together once more, on Thursday, the 5th instant, after the usual Christmas recess. It seemed as if many of them had come to the Club for this especial purpose, for there was a very full attendance; but in reality there was a great attraction in the subject which was down for demonstration and discussion, for Mr. Saville Kent had promised a paper on "An Amateur's Essays in Three-colour Photography," illustrated by kromskop lantern pictures.

Mr. Saville Kent is well known to the Camera Club, and to others, as an ardent naturalist and a skilled photographer. His lecture upon his lizard pets is well remembered, and no one is likely to forget the splendid series of pictures which he exhibited at the Crystal Palace not long ago, to say nothing of the books which bear his name; so that Mr. Saville Kent came before the Club once more with that zest of all guarantees, the kindly good-will of an appreciative audience.

The lecturer may fairly lay claim to being the first amateur to go thoroughly in for three-colour work, and that he has done so was soon evidenced by the remarkably fine pictures which were thrown on the screen by Mr. Ives's kromskop lantern arrangement. This instrument, it will be remembered, possesses three lenses, with only one luminant, and by it three-coloured discs can be shown separately, or superimposed by the touch of a lever. In the instrument used on the present occasion the registration was very perfect, but the light was poor, and unfortunately the effect of the pictures was to some extent spoilt by scattered light. We were not surprised to learn that the examples shown were far more effective when seen in the table form of kromskop.

Mr. Kent opened his discourse with a few remarks as to the great advantage of being able to secure coloured representations of natural-history objects without the help of fallible hand or brush work. The pictures which he had to show were about fifty in number, and represented the pick of 400 negatives which he had taken with the Ives apparatus. All the pictures had been taken during the last four months, and they were not intended to demonstrate the scientific aspect of colour photography, but to show the use of the process in the hands of a naturalist like himself. He was shortly going again to warmer climes, and he hoped, by help of the three-colour apparatus, to photograph the organisms of the tropical seas, coral reefs, &c., and thus reproduce the colours of some of these gorgeous products of Nature's laboratory in a manner which would be quite impossible with pigment and pencil. He was convinced that much could be done with the kromskop in this way, and he trusted that his own humble efforts in this direction would constitute a mite towards the realisation of the project.

The first examples shown were a series of beautiful orchids from the collection of Mr. Smee, of Carshalton, who had kindly given the lecturer every facility to photograph them in his greenhouses. Some of these flowers were of the most gorgeous description, and Mr. Kent had added to their effect by introducing moths, butterflies, and humming-birds into the various pictures for the purpose of colour contrast. These were not put in in a haphazard way, but with a keen eye to composition and artistic effect. Thus a yellow-toned orchid would have near it a blue butterfly, the two colours enhancing the brilliancy of one another. Yellow, by the way, seemed to be the most difficult colour to represent in this manner, and the greens also lacked the richness of nature. The reds and blues, on the other hand, left little to be desired. The orchids, beyond their beauty, are chiefly remarkable for their long names; but one, at least, had a little romance attached to it, for it could not be obtained until a certain man-eating tiger in Nepal—where the plant alone is found—had been dispatched.

The pictures next shown brought us nearer home, for they were taken in that paradise of botanists, Kew Gardens, some in the open air, and some (as, for example, the gigantic *Victoria Regia* lily) under cover. Once more at the Antipodes, we were shown a beautiful assemblage of moths on a tree trunk, photographed, of course, from dried specimens, some corals, and a tiny baby lizard, which, on the first day of its life, we were told, ate some beef steak, cut up small. Some more lizards followed, and these pictures illustrated in a remarkable manner how well neutral and metallic tints are shown in the kromskop. A made-up picture of gold and silver carp, apparently swimming in their natural element, brought the Exhibition to a conclusion with a remark from the lecturer that snap-shooting with coloured screens was at present in its infancy.

Mr. Stroh, who occupied the chair, congratulated the lecturer upon the success of his work, and remarked that the pictures were the best of their kind which he had yet seen, and he invited members to discuss the matter, which was one of supreme interest to photographers.

Mr. Ward, who had for a long time been associated with Mr. Ives in exploiting the kromskop, told how he had watched the dawn of the in-

vention years ago at Philadelphia. The Americans did not see the value of the thing. One said Ives had got colour photography on the brain, another remarked that it was a pity he did not turn his talents to something more useful, and so on *ad libitum*. Mr. Ward advised Ives to come to England, where he would have the opportunity of consulting Abney and others who were interested in the question of colour photography. Many of the pictures shown by Mr. Saville Kent he considered quite as good as those produced by Mr. Ives himself. He believed that the kromoskop method of showing coloured pictures put every other system into the shade, and, now that they had a camera and multiple back for taking these pictures with comparative ease, few could tell what a wide future was before it.

The Rev. F. C. Lambert offered the lecturer his congratulations for the magnificent results which he had achieved. He would point out that the dry-as-dust scientist had once more turned up "trumps." The photographer is now beginning to see that the scientist, working quietly and unostentatiously in his laboratory, is in reality laying the foundation for all good practical work. It was that great man, Clerk-Maxwell, who might truly be said to be a century in advance of his time, who worked out the colour curves in his Cambridge laboratory, upon which all succeeding experimenters have had to base their work. We are too apt to despise the scientist, as Captain Abney had reminded us over and over again; but, as photographers, we owe these men a deep debt of gratitude, and should bear this in mind as we come in at the finish and take all the cream off the bowl. We do not do half enough in this country to promote scientific research, a string upon which the late Professor Tyndall was always harping. He looked forward to the time when scientific men, freed from all cares and worries, would be able to work out these natural problems, which were so important to mankind at large.

Mr. Sanger Shepherd gave an interesting *résumé* of the three-colour process from Clerk Maxwell's work in 1861, when imperfect results were shown at the Royal Institution—imperfect, because there was then no sensitive plate which would give the whole range of the spectrum, and no means of making colour-screens, the aniline dyes not being then available to the purpose. He reviewed the work of Ives, and showed how the introduction of the Spectrum plate was of enormous value to the process.

The Chairman then invited Mr. Saville Kent to give his hearers some sketch of his manner of working out the three-colour process: in response to which hint, Mr. Saville Kent said that he would be only too happy to give any information in his power.

The first difficulty to contend with was the English climate, which made the question of exposure so uncertain. In ordinary photography waste glass soon began to accumulate; but since he had taken up the triple method he had started a greenhouse. At first he used nothing but Lumière's plates; but more recently he had employed Cadett's Spectrum plate. He developed his plates with metol, by Ives's formula, with consequent ruination to his finger nails. The exposures were very long, averaging fifteen to twenty minutes for the red screen, eight for the green; and a short time for the blue, the stop used being *f*-22. He developed in almost complete darkness; but those whose fingers were sensitive enough to distinguish the right side of a plate would find little difficulty in that direction, the great difficulty was the constant variation of the light, due to our inconstant climate. The proceedings closed with the usual vote of thanks, and many went home meditating the addition of a multiple back and coloured screens to their ordinary equipment.

#### THE MAKING OF A PICTURE.

THERE was a good attendance of the Leeds Photographic Society on Thursday evening, 5th instant, to hear Mr. W. E. Tindall, R.B.A., lecture upon "The Making up of a Picture." In introducing the subject Mr. Tindall said that "Hints to the Picture-makers" would be a more appropriate title, and any hints, such as they are intended for the benefit of those who wish to take with the camera, something which to them shall be more than a mere portrait of a given place.

In looking at pictures you should ask yourselves, "What is the principal intention?" and, having satisfied yourself, endeavour to put yourself in his position and see if the artist has carried it out properly, or as you would have done; and, if not as you would have done, Why?

"Although the plate will give you the drawing you require, I think that a knowledge of drawing to the photographer is of the highest importance; it strengthens many of our faculties, such as memory and observation, and these play a very important part in picture-making. We can achieve little without them; it is impossible to paint an effect while it is there, the best we can do is to make a few rapid notes to assist our memory, and of course the subject will supply the detail and form. This applies with equal force to photographers. Another study most useful to the art worker is perspective. Perspective to the picture-maker is what grammar is to the writer—both necessary adjuncts to production. You would often find it difficult to express your thoughts clearly, but a knowledge of the primary rules of perspective will help you immensely. It is most important that you should understand the principle of perspective, particularly for portraiture, in that you ought to

make the spectator feel that the head is completely round, that it has a back as well as a face. You hear some one complaining that the portrait is simply a mask and sticks to the background; the fault is in aerial perspective."

Referring to colour, the lecturer said it was almost as necessary to the black-and-white man as to the painter. There are several kinds of black and several kinds of white; "the black you want should be a rich, juicy, succulent black, a black with power in it and yet tenderness, a black that will suggest space and not give you the impression of a grey piece of paper."

"The white you should use is not white at all. Did you ever see white in nature? If the sun is shining, and you stand up so that your back is to the sun, you will see your form outlined on the ground. This is called a shadow, simply because you have shaded or prevented the sun shining on the place. This shadow has not added anything on to the ground, it has taken something off—sunlight, or, in other words, light. Thus I think you will see, if you wish to represent "light," you must have warmth, and white is not warm, it is cold."

#### THE THREE-COLOUR PROCESS IN GERMANY.

To the pages of the *Photographic Times Almanac* (New York), Herr Otto Gantzer sends the following instructive account as to the position of the three-colour process in Germany:—I presume that the reader is perfectly *au fait* in regard to the process itself, and therefore confine my remarks simply to the impression one gets from studying the many three colour prints one sees in this country daily, and to such points of interest which I have gleaned in conversing with practical men—engravers as well as printers—whom it has been my fortune to meet here.

"Of the more prominent 'Kunst Anstalten' in this country there is only a baker's dozen, and hardly that many, whose work comes up to a fair average, and of these again are only three or four who will furnish work of a really meritorious character. Among these, strange to say, two of the largest and best-known firms are missing, Meisenbach, Riffarth & Co., Munich, and Anerer & Gössel, Vienna, who do not favour the three colours, but still employ the old process of chromotypy in five and more colours. The Vienna firm's objections are mainly of a theoretical nature, as they contend that many grey, blue, and green tones cannot be reproduced by this process, and that the complexity of this process with the repeated copying and transferring, and the loss of detail occasioned by this, makes the process unsuitable for real art work. To my mind, these reasons do not stand, or the firm mentioned has had no occasion to see the reproductions of later years, which by actual comparison with the original drawings prove to be facsimiles of so high a merit, that it is impossible to believe another colour more would improve the work in any degree. What the addition of another or more colours would undoubtedly bring about is the loss of the artist's technique, a blurry indistinctness of the whole picture—two points which it is the good fortune of a correct three-colour print to entirely eliminate from the possibilities of this process. Of course, there are colours which cannot be reproduced at the present condition of this process, as cobalt blue and its components, all the electric greens, &c. But this is not the fault of the process, but of the colours and inks as manufactured."

"The process of making the plates is practically the same here as with us. The main difficulty lies in the intelligence and carefulness of the photographer. Correct negatives properly toned down ensure good results and materially lessen the labour necessary for correcting the printing plates. This labour, here in Germany, of etching, re-etching, hand-tooling, and retouching amounts to a great deal, in fact it seems to be the whole secret of the process, since the necessary negatives are generally made in three or four days, while the printing and finishing of the plates takes as many weeks. Orthochromatic dry plates are used for the first exposure, wet plates for the screen negatives, a hard negative generally gives the best results. I found the Carbutt colour filter mainly in use, and in only one or two instances came I across dry collodion filters which were not factory-made. Aniline colours in alcohol are used here for these filters, which, however, change easily, no matter how carefully kept, so that the spectroscope is constantly employed to determine their condition. Where a spectroscope is not available, trial exposures should be made from the three colours, which, in the form of printing inks, are rubbed on to paper. Then it will be seen if the filter shuts out the corresponding colours. Filters are carefully kept in a steady temperature of 75° F., and are used behind the lens and close to it. Lenses are to be carefully selected, such without a chemical focus; they are apt to throw pictures in different sizes for each different colour. The anastigmats of German make give good satisfaction. The Levy screen—175–150 lines—is exclusively used here; it should be turned exactly 30° for each colour to escape the so called *moire*."

"In this whole process everything, of course, depends on the proper adjustment of the three negatives to each other. The red plate is considered the worst one of the lot and gives the most trouble. Up to date there is no such thing as a faultless red negative, which could be used without retouching; the main difficulty, however, lies in the copying, and printing, and etching from these negatives, in the work of putting the three printing plates in proper accord to each other. At this

point mention must be made of the work of Dr. Selle, who invented the art of putting three coloured gelatine films over each other and thereby produces a diapositive from nature. The greatest merit by far of his work, however, is, that his negatives and positives do not require any retouching, and, as I happen to know, are not retouched in any manner. Dr. Selle is an amateur, and furnishes the negatives to gelatine printers, who get excellent results by treating the gelatine plates in the ordinary manner. His exposures with dry plates and daylight are timed by seconds, while other workers in daylight use 2-5 minutes for one exposure, and with electric light as much as an hour. The time of three exposures is in the proportion of 1 to 4 to 12 according to the colours. Among the publications of recent date, two especially have drawn the attention of the interested public. One, a set of twenty tables, representing flowers and plants, made by Husnik & Haeusler, Prag; the other a set of some dozen animals, from the works of George Buxenstein & Comp, Berlin, are the *ne plus ultra* of three-colour prints ever published on this or any other continent.

"Comparing these with the original drawings, it is evident that no artist lithographer could reproduce them more true in colour and tone or show the technique of the artist to better advantage. As a rule the German printer, who cultivates this class of printing, submits his prints or proofs to the artist, who drew the original, and follows the suggestions of this critic in every way. That the result thus obtained is a highly creditable one goes without saying for him who knows the highly developed state which the art of painting and drawing has reached in this country. The fact, that all the best-known and most celebrated professors and teachers of painting of this country have expressed their satisfaction with the results which may be obtained by this process speaks certainly worlds in favour of it.

"And now a word about the printing from such plates. The best press here in use for this class of work is a stop cylinder, built by König & Bauer, with improvements suggested by the foremost practical printer of this country, Mr. George W. Buxenstein. It is a stop cylinder, with perfect ink works and a special arrangement to ensure absolute register, runs at a speed of about 1000 per hour, and permits to keep the loss from bad register and other sources down below six per cent. Printing editions of more than 10 000 the loss falls still below that figure. Each colour must be allowed to perfectly dry before running the second colour; absolute evenness of temperature is necessary to keep the paper from stretching or shrinking; and cleanliness and a careful handling throughout are required.

"The Germans have, no doubt, succeeded to make this process useful for many purposes, as it is applied to publications of art and science where, in many instances, the limited art of the lithographer has failed to do full justice to the work. The Germans also have succeeded to reduce the cost of such work to a point that it may well compare with work done in eight colours from stone and be infinitely more meritorious from an artistic standpoint, which leaves no doubt to my mind that, in this country at least, the three-colour process has a future in store and will in time revolutionise all colour processes in existence at present."

#### VARNISH A CAUSE OF SPOTS ON NEGATIVES.

In the December number of *Photographic Scraps* appears the following note on a hitherto unsuspected cause of spots on negatives. A correspondent writes to the Britannia Works Company: "I am sending a negative for your inspection. Will you kindly examine same and state the cause of the spots? My negatives are well washed, and I allow at least fifteen minutes for fixation, with hypo of the regular strength. I have found spots on several other negatives that did not show when first printed from, but, after storing, spots appeared. It has been most trying to me, as these spots have appeared almost always on the most valuable negatives from which I wanted reprints. In most cases the spots have not been noticed until some time had elapsed, but in this case they appeared within a few days. I am sorry about this, as it is the only fault I can find with your plates, and I feel satisfied that the fault is not yours, but is due to something in the working. I say this because of my past experience of many years. I have used many thousands of your plates.

The Company remark: "The above letter was accompanied by a first-grade studio portrait negative, literally covered with minute bright reddish-brown spots, so close together that the film was practically one mass of colour, and useless for printing from. The negative had been varnished, and when we removed the varnish, as a preliminary towards an investigation, the spots were found to be on the film. They were of such a nature that no previous experience of ours could explain their cause. We therefore asked for more negatives and for more information, putting special questions about the varnish used, and how and when it had been employed. These inquiries elicited the facts: (1) that the spots only arose in the case of negatives that were varnished; (2) that they had only appeared since the last lot of varnish bought had been in use; (3) that when first this varnish had been used the spots were infrequent and not serious; (4) that the trouble had been getting gradually

worse, more general, and earlier in appearing after the negative was made. The source of the trouble was clear: the varnish was impure, and, by keeping, its impurity increased. The bottle was thrown away, and a new supply obtained, with the result that no more spots were seen."

#### THE OPTICAL LANTERN FOR SCHOOLS.

THAT the magic lantern is increasing its sphere of usefulness is undeniable, here, there, and everywhere, it is found assisting in all classes of work. At the Perth School Board last week a proposal was brought up from the Works Committee to have one of the class-rooms in the Southern District School fitted up for magic-lantern displays. This, of course, immediately put the economists (?) on the defensive. Mr. Masterton moved disapproval of the proposal. As an argument against the lantern he instanced the big schemes already in hand by the Board; the lantern scheme would cost not less than 100*l.*, and he thought could be well delayed. Mr. Bridges seconded, he was unable to see any use of a lantern at all. Mr. Ramsay moved approval of the proposal. It was now almost impossible to teach geography to large classes without representations on screens; the cost would not be over 25*l.* expenses.

Baillie Love was against the proposal, it was all a fad; Mr. Ramsay, he thought, was amusing in the extreme; how had their forefathers and the present generation learned geography without magic lanterns? It was folly to encourage a teacher in nostrums of this kind. The Chairman (Mr. F. Norie Miller) supported the proposal, remarking that the Edinburgh School Board, who were possibly almost as enlightened as the Perth Board, had gone in for lantern teaching. In reply to the discussion, Mr. Masterton said they were up to the neck in debt, hence he was against this expenditure. On a vote being taken, four voted for the lantern and three against it; the lantern will therefore be one of the educational agents under the Perth School Board. Probably this action has been instigated by some of the energetic members of the local Photographic Society.

#### WEIGHTS AND MEASURES.

THE question of weights and measures is unfortunately one which is always proving harassing to photographers, and probably always will till the metric system drives out our own bad British systemless "system." Confusion is often caused by the use of the term "per cent." or the symbol "%," in several different ways.

Suppose we have a solution of, say, potassium carbonate in water, and we wish to express the relative proportion of water to solvent, we naturally select some standard which we can also apply to other solutions. That is the object of the percentage system, whether units of volume or weight are used. It is in the careless use of these units that confusion is introduced, for we can make use of either (or both) weight or volume. We can say that 100 parts by weight of the solution (100 grammes, let us suppose) contain 50 parts by weight (50 grammes) of potassium carbonate. This is what most technical and purely scientific text-books would call a fifty per cent. solution. The units both of solvent and solute are those of weight.

Now, the specific gravity of this particular strength of potassium carbonate solution is 1.544. Hence 100 grammes will occupy a volume

$$= \frac{100}{1.544} = 64.8 \text{ c. c.}$$

Since weight = volume and density.

This means that 64.8 c. c. of the solution contain 50 grammes or (by simple calculation) 100 c. c. contain 77.2 grammes.

The difference between the two modes of expressing the same thing will be apparent if we place the results side by side.

#### POTASSIUM CARBONATE SOLUTION.

Sp. gr.	Grammes per 100 grammes.	Grammes per 100 c. c.
1.544	50.0 grammes.	77.2 c. c.

Photographers will always prefer measuring solutions to weighing them, and therefore the second mode of expression is that which they will wish to adopt.

Unfortunately, the photographic formularist has got to call this second solution a "percentage" solution. Etymologically, it is, but as a matter of fact the units of weight are generally understood to be used in an expression of strength in "percentage."

We have treated this point at some length because we wish to allude to some suggestions which have been published in a German contem-

porary\* with regard to the adoption of a symbol which shall point out what mode of expression is being used.

Dr. O. Everhard suggests—

$p/00$  for percentage by weight.  
 $v/00$  " " " volume.

Thus, a potassium carbonate solution of sp. gr. 1.544 would be written as "50  $p/00$ ," whilst a photographer's so-called "ten per cent. ammonia" would be dilute "ammonia ('880)," 10  $v/00$ .

We still require, however, a symbol for the mixed relation of weight per volume (or of volume per weight), and for this we would suggest that Dr. Everhard's symbols be amplified as follows:—

Percentage weight per weight .....	$p/p00$ .
Percentage volume per volume .....	$v/v00$ .
Percentage weight per volume .....	$p/v00$ .
Percentage volume per weight .....	$v/p00$ .

Thus, to revert once more to our potash carbonate solution, it might be written either as "50  $p/p00$ ," or as "77.2  $p/v00$ ," and in each case the reader would be under no doubt as to what was meant.

This system of nomenclature is, of course, applicable to any system of weights and measures having a simple relation between its units of weight and volume.

G. E. BROWN.

### HILL'S REFLECTING CAMERA.

THE improvement consists in attaching a blind shutter of peculiar construction, marked A in the drawings, to a reflector, so that a full-size image may be seen up to the moment of exposure on the focussing screen, B<sup>1</sup>, which is on the top of the camera and of the box form.

The reflector is hinged or pivoted at one end, and free to move from a position parallel to the focus screen to an angle of 45°.

At the top and bottom of the camera, and in a plane with the back of the lens, spring rollers are fixed (marked D in drawings), each pulling in contrary directions.

The top roller will have means whereby an increased tension may be given by winding.

A blind, marked A in drawings, is attached to these rollers, which is

pierced by an opening, marked F, and the free end of the pivoted reflector, B, is attached to the blind, so that one-half the blind is above the reflector and one-half below.

Drawing No. 2 shows the shutter when at about an angle of 30°, and the construction preferred of roller and blind, but it is obvious that two separate blinds with apertures, affixed at edge of reflector, would answer equally well.

\* Chemiker Zeitung, 1898, pp. 28, 93.

To obviate any chance of light penetrating the top aperture, a small blind of opaque fabric may be hung from edge of focus screen, marked H.

The camera is set for exposure by drawing down the reflector by means of a pin piercing a slot in the side, and affixed to the mirror, or preferably the pivot would pierce the side of the camera at point C, and be attached to a lever working outside the camera, which is held and released by some such simple catch as shown in drawing 3. This catch, J (fig. 3), is a bent lever pierced by a screw, which acts as a fulcrum, and is notched so as to hold the lever, K, when at an angle of 45°. When the lever, J, is pressed on the lower end, towards the body of the camera, the exposure is effected by the lever, K, being released.

When, however, the lower end of the lever, J, is pushed towards the front of the camera, the lever, K, is also released, but in this case, the lever, J, being free to move on the screw, the upper end catches the lever, K, when at about an angle of 15°, checking the mirror when the lower aperture is opposite the lens, and continues its movement when the pressure is relieved, as it is drawn out of its path by a small spring, N.

To obviate vibration, the mirror may with advantage be of metal or other suitable material.

### DESCRIPTION OF DRAWINGS.

A, blind; B, reflector; C, pivot; D, rollers; F, aperture; G, body of camera; H, cut-off; J, catch; K, lever; L, focal plane; M, lens aperture; N, spring.

### THE KOZY POCKET CAMERA.

FIG. 1 is a perspective view, showing the camera opened. FIG. 2 is also a perspective view, showing the camera closed, the door through which the film rolls are introduced being opened. FIG. 3 is a side elevation of the camera opened, the outer casing, or framework, being indicated by dotted lines, the interior mechanism being shown in full lines. FIG. 4 is a similar view of the same parts with the camera closed, and containing an independent plate-holding device. FIG. 5 is a plan view of the film-supporting platen and connexions removed. FIG. 6 is a rear end elevation of fig. 5.

The camera box, or casing, is made in two parts, 10, 12. By a hinged connexion at the rear ends thereof said parts are held together, and movement thereof is permitted for swinging the free ends of said parts

one from the other in order to open the camera box for use, as shown in figs. 1, 3. Between said parts a folding bellows, 14, of light-excluding material, is arranged for excluding light in the usual manner. Said parts are supported in open position by a bar, 16. Said bar has one end in pivotal connexion with the part, 12, and has its other end in sliding connexion with a rod, 18, attached to the part, 10, this being in order to permit the movement required of said bar in folding the camera parts together, as shown in fig. 4.

In the outer, or free end of part, 10, is located the lens and its shutter connexions. This arrangement is an important feature of this invention. By it the obliquely arranged lens is brought into focal position, perpendicular to the film-supporting platen, 20, by the simple operation of opening the camera, and it allows of the platen being securely and economically connected with the part, 12.

In carrying out the arrangement of platen, 20, within the chamber of

part, 12, the inventor has had in mind to arrange for the introduction of an independent plate-holding device, 24, (fig. 4.) To this end the platen-supporting connexions are made adjustable, whereby movement of the platen adjustably is allowed from the focal plane, as shown in fig. 3, to a plane there below, where upon the independent plate-holding device, 24, of usual construction for holding glass plates, may be introduced through a suitable opening at the back of the camera part, 10, and rest upon the platen, 20, all as shown in fig. 4.

The platen, 20, is form d of sheet metal with roller connexions, supported at the sides thereof in the usual manner. At the front and back ends of the platen and integral therewith are downwardly extending plate-projections, 40, 42, formed by overturning and projecting down-

wardly the platen metal. Said plates are made to bear in sliding connexion one with the inner face the back wall of part, 12, and the other against the face of supporting block, 28, and they are held in place by screws, 30. Said screws being located in oblong slot, 32, 34, have only to be loosened in order to permit the platen being moved to different planes of altitude below the focal plane.

Supported for movement rotatively in the rear end of part, 12, is the stud, 44, on which to support one end of a film-holding roll, and it has winding connexions to engage the spool at that end. On the plate, 40, is a stud, 46, whereby to support the other end of said winding spool. The spool from which the sensitised material is taken is supported on the studs, 48, 50, the film being made to pass over the platen, 20, is thereby supported in the focal plane. To permit the described adjustment of the platen, 20, plate 42, has an oblong recess, 52, allowing for the winding stud, 44. The plate, 40, is cut away from the platen, 20, except at the central part thereof, as shown in fig. 2, in order that the end portions thereof may be sprung outwardly as indicated by dotted lines, (fig. 5,) and thus permit introduction and removal of the film-holding spools. The normal tension of said parts in springing back to place operates against the end faces of said spools and gives a tension thereto for holding the film tightly drawn. For ordinary purposes this tension is sufficient, but a spring is provided in support with the part, 28, and bearing with its ends against the plate, 40, as shown in fig. 5. The supporting block, 28, will be understood as having a fixed connexion with the frame part, 12. The lens and shutter devices are supported by a block, 60 (fig. 4), whilst 76 (fig. 1) indicates a shutter-releasing push button, and 68 is a shutter-setting device.

#### KRUGENER'S IMPROVED ROLL-HOLDER.

This is an improved form of roll-holder, constructed in such a manner that it may either be made use of independently from or in connexion with the detective camera.

It forms an independent body, and no part of it is attached to the camera, the latter being thus fit for use without a roll-holder.

Fig. 1 represents the camera with the spool-holders and screens, viewed from above.

Fig. 1a gives a vertical view of the spool-holders and the manner in which they are mounted.

Figs. 2 and 3 show a modification in the method of attaching and screening the spool-holders.

In the first form the roll-holder is composed of two metal plates, *a* and *b* (fig. 1a), which are screwed or fastened together by two obliquely arranged partition walls, *c* and *d* (fig. 1), the whole thus forming a separate body, whilst the partition walls act as screens and prevent the light transmitted by the lens or objective from falling on the spool-holders and film thereupon.

The improved roll-holder contains four rollers, two of which, *i* and *k*, are small and merely act as runners for guiding the film in its passage from one spool-holder to the other. The other two, *f* and *g*, are mounted on studs on pins, *h* (fig. 1a), which are attached to the two metal plates, *a* and *b*, mentioned above.

The film thus passes from the supply spool, *f*, over the runners, *i* and *k*, to the receiving spool, or "clamping reel," *g*. This latter is turned by a key and winds up the film, *m*, subsequent to the exposure.

When employed in a detective camera, the improved roll-holder, which, as already stated, forms a separate body, is placed in the camera, the key being then applied from the outside. Care is then taken that the position of the film coincides with the plan of the focussing screen, and, when this is accomplished, the back cover, *l*, of the camera is put on.

The improved roll-holder may also be made in the following modified form:—

The large rollers (spool-holders), *f*<sup>1</sup> and *g*<sup>1</sup>, hidden or screened by partition walls, *c*<sup>1</sup> and *d*<sup>1</sup>, are mounted on a wooden board, *l*<sup>1</sup> (figs. 2 and 3), forming the back cover of the camera. In this case also the film, *m*,

is kept in exact register by means of two runners, *i*<sup>1</sup> and *k*<sup>1</sup>, attached to the back cover, *l*<sup>1</sup>, in such a manner as to facilitate the winding of the film. The back cover, *l*<sup>1</sup>, at the same time acts as a table or backing for the stretched film, *m*.

When it is desired to use the camera without the improved roll-holder, the board, *l*<sup>1</sup>, is replaced by an ordinary back cover, *l* (fig. 1).

The main feature of the present invention being the provision of a separable or detachable roll-holder, no stress is laid upon the special construction of the spool-holders, which may be of any convenient form.

#### THE CAMERA CLUB.

The following notes, abstracted from the January number of the Camera Club Journal, relate to some very interesting subjects that are to be brought before the Club at its evening meetings during the present month. On January 16, Mr. Horace Brown, F.R.S., will deliver a lecture on "Prehistoric Remains in Greece." The Society of Photographic Etchers has shown, in the last members' Exhibition, what can be done with comparatively little practice. It is announced that, on January 19, Mr. E. Sanger Shepherd, who is well known both as a scientific and

practical worker, has consented to instruct the members in his "Modifications of Photographic Etching." Mr. C. J. S. Makin, an old photographer, will, on January 23, illustrate his "Recollections of Life and Scenery in many Lands"—principally on this occasion in Eastern lands—with a large number of descriptive slides. The next Club-house dinner will take place on Tuesday, January 24, at 7.30 p.m. Owing to the success of the meeting last year, it has been decided that this shall be a cyclist dinner. In connexion with this dinner, the Hon. Secretary intends to have, on January 24 and 25, a small exhibition of cycling novelties and accessories, particularly those connected with photography. On January 26 an account of the "Recent Soudan Campaign" will be given by Mr. W. T. Mand, the Special Correspondent of the *Graphic*, illustrated by slides made from his sketches. On January 30, an interesting series of slides of scenery and architecture in the British Isles will be shown and described by Mr. E. Duckree, who is well known for the excellence of his work and the charm of his pictures. Chief Justice Rayner, of Lagos, has come home on short leave, and has promised a description of life and scenery in that colony before he returns. Surgeons-Major Morgan and Eckersley have promised a lecture on "Campaigning in East Africa."

### PROPOSED UNION OF YORKSHIRE PHOTOGRAPHIC SOCIETIES.

MR. EZRA CLOUGH, Hon. Secretary (*pro tem.*), of 13, Chesham-street, Bradford, has addressed the following invitation to the Hon. Secretary of each photographic society in Yorkshire:—

"You are invited to attend a meeting of gentlemen, with a view to forming a Union of Photographers and Photographic Societies in Yorkshire, to be held at the Bradford Grammar School, on Friday, January 27, at 7.30 p.m.

"Among the probable advantages of such a Union may be mentioned: united action for the purposes of exhibitions, competitions, and matters of general importance; interchange of lecturers, lectures, prints, and slides.

"Please invite one or two of your members to accompany you."

We are asked to state that, if Mr. Clough's letter has failed to reach the Secretary of any Yorkshire society, the publication of this notice may be regarded as equivalent to an invitation to be present at this meeting.

### MID-CHESHIRE EXHIBITION.

THE opening of the Verdin Technical Schools, Northwich, the munificent gift to that town of Sir Thomas Verdin, offered an opportunity, which the public-spirited Committee were not slow to take advantage of, by arranging for an Industrial and Art Exhibition. An excellent and representative collection was brought together. The Photographic Section, which alone concerns us, was, without being noteworthy, a very promising show, especially so as it was the first of the kind in Northwich. The photographs were divided into nine classes, seven being for photographs of a general character, one for stereoscopic views, and another, divided into ten sub-sections, for lantern slides, no picture which had previously received an award being eligible for competition.

The Judges were Mr. George E. Thompson and Mr. G. Watmough Webster. Five bronze medals were awarded in the general classes, and one silver and one bronze medal for lantern slides. Of the five medals, one in the Enlargement Class was awarded for an enlargement, a view of *Lincoln Cathedral*, by Mr. A. H. Burgess, a technically perfect print. Dr. Marsh, who had a remarkably good collection of Röntgen-ray prints, among them being one, almost unique, embracing the whole of a human figure, from the occiput to the last metatarsal phalanx, was justly entitled to, and received, a medal.

A simply posed, well-lighted, small portrait study of a young girl in a blouse (so faded as to be almost invisible) had much merit and received a medal. The exhibitor also received a medal for a pretty landscape. Mr. J. Dean's *Cheshire Lane* was a pretty woodland scene that, with a little more care, might have been a striking picture: an inch cut away from the top of the print and a figure suitably introduced in the foreground would have wonderfully improved it. A silver print of a triumphal arch, with the flags garishly coloured by hand, should not have found its place in this collection, topical interest though it possessed. Two large views (not for competition) of Messrs. Brunner Mond's works, taken under most difficult circumstances from the summit of a large chimney, were very interesting, and gave an excellent idea of the vast industry connected with their name. *En passant* we may say that they seem to manage these things well in Northwich, for on our visit we were disappointed in seeing no buildings out of perpendicular, nor any gaping cavities in the high roads, as recent newspaper accounts led us to expect. But when a building goes wrong there they simply get screwjacks to work, and have it put square in a very brief space of time. We did not notice in the Exhibition a single representation of this remarkable state of affairs. Above all, we expected to see, but did not

see these Northwich catastrophes represented in the Lantern slide Section. The silver medal, awarded to the President, was obtained by four beautiful slides, well printed, rich in tone, representing incidents of an athletic gathering; the exposures must have been very brief, for, whether tossing the caber or dancing a highland reel, the figures came out with remarkable sharpness, vivacity being the keynote of the set. Gymnastic exercises—a set of lantern slides by J. Lyon, and representing a number of performers in each of the various positions beloved of the gymnast: horizontal, vertical, heads up, feet up—were an equally good set of slides, but with less variety than those of the silver medalist, received a bronze medal. Altogether the small Exhibition must encourage the promoters, and lead them to hope for still better things in the future.

## Our Editorial Table.

### A NEW SPIRIT LEVEL.

Taylor, Taylor, & Hobson, Slate- and Steel Works, Leicester.

MESSRS. TAYLOR, TAYLOR, & HOBSON have been studying to make circular spirit levels more reliable and permanent, and they send us a sample, together with the following details, of its construction: The spirit chamber, is made in one close-grained homogeneous piece by squeezing from a flat aluminium sheet. It is pointed out that this white metal enhances the contrast between the colour of the bubble and that of the surrounding spirit. The connexion between this chamber and the glass, B, is now made of such a form that any expansion of the metal is compensated, and the joint is not opened. Leakage is further prevented by the elastic ring, D, which is compressed into the angular

space of the joint. The level is assembled by forcing the chamber, A, into the outer jacket, C, until it comes into contact with the glass at A. The rim of the jacket at C guards the glass from injury, and this outer jacket, being separated from the spirit chamber, may be strained or bent even considerably without causing the level to leak. The new level, which retails at the low price of one shilling, should find favour at the hands of those photographers who appreciate scientific accuracy in the construction of the instruments they employ.

We have received from Mr. W. H. Fletcher, background specialist, of Kepler Villa, Wombdon-road, Bridgwater, several photographs of his specialties in backgrounds, interiors and exteriors, and graduated and cloud effects. These evince great taste in design, and are evidently the work of a skilful artist in this branch of work.

## News and Notes.

We are sorry to learn of the death of Mr. Richard Keene, photographer, of Burton-on-Trent, who passed away on the 5th instant, in the forty-seventh year of his age.

ROYAL PHOTOGRAPHIC SOCIETY.—Photomechanical Meeting, Tuesday, January 17, at eight p.m. "On some New Half-tone Screens of English Manufacture," by J. E. Johnson.

A NEW book on *The Platinotype Process*, by Mr. W. J. Warren, will be published immediately by Messrs. Iliffe, Sons, & Sturmer, Limited, 3, St. Bride-street, Ludgate-circus, London, E.C.

THE gold medal offered by the editor of *Darlington's Handbooks* for the best photograph taken by travellers during 1898 has been gained by Mr. J. Kearney, Liverpool, and the second prize by Mr. R. Brookes, Norbiton, London.

ERRATUM.—Mr. Richard Penlake writes: "There is a small printers' error in my article on p. 3 of the *LANTERN SUPPLEMENT*: 13×8 cm., third line from finish, should read 13×18 cm. Please make a note of this, as it is a very important point."

LAST week we omitted to mention that we were indebted to an old contributor and friend of the JOURNAL, Mr. T. Stokes, of Clare, Suffolk, for the excellent little article, "A Convenient Arrangement for Copying." It was received too late for our ALMANAC.

**PHOTOGRAPHIC SOCIETY OF IRELAND'S EXHIBITION.**—The Hon. Secretary writes: "I shall be glad if you will kindly draw your readers' attention to the fact that the last day for receiving entries for our Annual Exhibition is Saturday, January 28. Particulars, labels, &c. can be had from me."

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—Members and friends are reminded that the Annual Dinner of the Society takes place on Saturday, the 21st inst., at 6.30 p.m., at the Montpelier Tavern, Choumert-road, Peckham; tickets 3s. 6d. each. Intending diners, please advise the Hon. Secretary, Mr. A. E. Allen, 27, Princes-square, Kennington, S.E., this week at latest.

**MESSRS. MATTHEWS & CO.,** of Central Mills, Gough-street, Gray's Inn-road, W.C., inform us that they have opened an office in Manchester, at 49, New Bailey-street, Albert Bridge, for the sale of bullion and purchase of jewellers' and silversmiths' sweeps, and all residues containing gold, silver, and platinum. All sweeps and residues &c., forwarded to them will be prepared, sampled, and assayed, and full value returned as promptly as possible.

THE Scientific Press publishes this week a new text book on *Photomicrography*, by Mr. E. J. Spitta, who is already well known for his joint authorship of *An Atlas of Bacteriology*, and for his other photographic and scientific works. The book will be published in 4to form, with full-page plates and numerous illustrations, and will undoubtedly prove of the greatest interest to all those who are taking up the increasingly popular subject with which the book deals.

**REMOVING GREASE SPOTS.**—Mr. Pellechet writes: "I read in the last number of the JOURNAL (Friday, December 30, 1898, p. 835) a notice about doing away with grease spots. I can give you a very simple and trustworthy method, i.e., covering the spot, or the oiled place, with a powdered earth called *terre de Sommières*, which is sold in France by the ordinary druggists. (You must leave the earth on the spot twenty-four hours at least.) That earth is a very fine argile, the earth of which earthenware vessels and also porcelain are made. The earth drinks the oil, and, when you have repeated the application sever 1 times, if necessary, the oil or grease has disappeared from the paper (or the cloth, if a garment has been soiled)."

**POPULAR EVENING AT THE BRADFORD PHOTOGRAPHIC SOCIETY.**—A variety entertainment, especially for ladies and children, was arranged under the auspices of the above Society in the large hall of the Grammar School on Wednesday evening, January 3. Mr. Ezra Clough occupied the position of Chairman, or Master of Ceremonies, and about 140 people, including a large proportion of young folks, were present. The programme included numerous items by the gramophone, under the management of Miss Watson, songs by Miss Lily Ellison and Mr. R. O. Lawson, and a lantern entertainment by members of the club. Each child present received a toy or a game, a box of chocolates, an orange, and an apple. The affair was exceedingly successful, and reflected great credit on the sub-committee of the Bradford Photographic Society, which had the arrangements in hand.

**BIRMINGHAM PHOTOGRAPHIC SOCIETY.**—The Fourteenth Annual Exhibition will be held at the Royal Society of Artists, New-street, Birmingham, from February 27 to March 4, 1899. The Exhibition will be inaugurated on Saturday evening, February 25, by a private view and *conversazione*, and will remain open from 10 a.m. to 10 p.m. from Monday, February 27, to Saturday, March 4. The rooms are excellently lighted from the top (artificially by electricity), and admirably arranged for the display of artistic work to the best advantage. The Judges will be: Messrs. William Crooke, A. Horsley Hinton, and W. T. Wainwright, A.R.W.S. There will also be an exhibition of apparatus, cinematograph and lantern entertainment, vocal and instrumental music will be given each evening. The Hon. Secretary is Mr. C. J. Fowler, Court Mount, Erdington, near Birmingham, of whom all necessary particulars may be obtained.

**RICHMOND CAMERA CLUB.**—A popular lecture, entitled "The Camera and the Wheel," will be delivered in the Masonic Hall, Greyhound Hotel, on Monday, January 16, 1899, at 8.30 p.m., by Mr. F. O. Bynoe (B. & J. Beck, Limited). The following is the syllabus: 1. The Harmony of the two Pastimes. 2. How a Camera takes a Picture. 3. The choice of Apparatus and its required Scope of Work.—(a) The lens; how to know a good lens; what is meant by a single lens, a rectilinear lens, a fixed-focus lens (illustrated with limelight diagrams); the advantage of the fixed focus lens for snap-shot work. (b) Magnifiers (supplementary lenses), their use and theory (illustrated with mechanical slide). (c) The photographic shutter. (d) Something about films. (e) Magazines for hand or stand cameras. The Frena system (illustrated with mechanical slide). 4. Carrying the Camera on the Cycle, and the Cycle as a Tripod. 5. How to manipulate the Camera. How to hold the camera steady; result of jarring the camera when exposure is being made; the disappointing results frequently obtained when photographing subjects containing bright colours; how to obtain a correct idea of how a subject will appear in a photograph. 6. The Flashlight and how to use it. 7. Series of Lantern Slides showing Hand-camera Work in its various phases. Admission is free to the lecture.

**A CHARGE OF STEALING NEGATIVES DISMISSED.**—At the Thames Police Court, on the 7th instant, William Marshall, a photographer, of Devonshire-street, Hackney, was charged with stealing six photographic negatives, value 11. 16s., the property of Harry Randa, photographer, of Garden-street, Shadwell. The prosecutor, in the course of his evidence, stated that he had known the accused some time, and about five months ago witness missed the nega-

tives from 28, Jubilee-street. At that time Marshall constantly visited the premises. About a fortnight ago witness heard that some of the negatives were being exposed for sale in a shop in Whitechapel-road, where the accused had a studio, and he went and asked him how they came into his possession. Marshall replied that the negatives were given to him by William Read some years ago. Witness replied that that could not be, and that they were his property. He then said to accused, "If you return them at once, I won't press the charge; but, if you don't, I shall charge you." The magistrate: "In other words, you said you would compound a felony?" Witness further stated that, as accused did not return them, he gave him in charge. Replying to Mr. Phelps, who appeared for the defence, witness said he had seen the negatives, and those in the case were prints from them. On being pressed, however, witness admitted that he had not seen the negatives. One of the negatives was that of a barmaid he particularly wanted (laughter). Witness further admitted that in June last he gave prisoner two negatives, and he might have also given him mounts. He sold accused an engraving of the late Mr. Gladstone for 10s. 6d. On Friday last he sold prisoner's partner a pawn ticket for the lens. Mr. Dickinson, in discharging prisoner, advised him to give up the negatives he had in his possession.

THE firemen had a most difficult and dangerous task to contend with just before half-past one o'clock on Thursday morning, January 5, a fire breaking out in the premises of the London Stereoscopic and Photographic Company Limited, 54, Cheapside, E.C., two doors from Bow Church. The premises consist of a lofty warehouse of seven floors, extending about twenty yards in one direction, and running back about a third of that distance in another. The City Police constables patrolling the immediate neighbourhood discovered dense volumes of smoke pouring out of the basement, and it was soon apparent that a serious outbreak had originated in the stores, in this part of the warehouse, and was rapidly increasing in strength. Not a moment was lost in raising the alarm, and the firemen who were on night duty in Aldersgate-street, opposite the General Post Office, were apprised of the outbreak, information of the fire was also conveyed by a stranger to the brigade station in Watling-street, and in a very few minutes a number of ladders and steamers from Whitefriars, Clerkenwell, Whitecross-street, Bishopsgate-street, and Southwark-bridge-road, in addition to the Watling-street corps, were on the scene of the outbreak. The large body of firemen were under the direction of Commander Wells, R.N., the chief officer of the brigade. The smoke issuing from the basement was unusually dense, and was strongly impregnated with chemical fumes. These conditions, coupled with occasional explosions, prevented the firemen from getting at close quarters with the fire, and consequently their efforts for some time were unavailing, and considerable anxiety was caused to the various chiefs. Although the shop was well alight and full of smoke, it was found necessary to force an entrance into it, and cut away a large section of the flooring. Under the direction of Commander Wells, this operation was successfully performed, and by this means the origin of the fire was made accessible to the water. Five steamers were now in full working order, and at once set to work on the fire in the basement, which was glowing like a furnace, the result being that immense quantities of water were poured every minute through the apertures in the flooring. This system was eminently successful, and, after one hour's hard work, all cause for alarm was removed. The front part of the large basement was practically gutted, and its valuable contents destroyed. The back basement and the shop were badly damaged by fire, and the rest of the building suffered from the effects of heat, smoke, water, and breakage. For a considerable time after the flames were extinguished volumes of smoke curled up from the smouldering debris, and it was not until eight o'clock that Commander Wells felt justified in calling off his men. The damage wrought by the fire itself is not so extensive or costly as that done by the smoke, water, and breakage. A rough estimate places the damage at between 3000*l.* and 4000*l.*, which is covered by insurance in the Sun and North British and Mercantile Offices. The business of the firm is being carried on temporarily at the back of the building. The cause of the fire was at the time of writing unascertained. The following is the official report sent by Commander Wells to the London County Council: "Called at 1.37 a.m. at 54, Cheapside, City, E.C., to the premises of the London Stereoscopic and Photographic Company, Limited, and building of seven floors, about fifty feet by twenty feet; front basement, used as a store, and the contents nearly burnt out; back ditto, and the shop and contents damaged by fire; rest of the building and the contents damaged by heat, smoke, and breakage; 55, ditto, ditto. A. J. Jones, Limited, tobacconists, building and the contents slightly damaged by smoke, heat, and breakage. 1, Bow Church-yard, ditto, Mr. Gulliver, tailor, building and the contents damaged by smoke, and the doors broken open. 5, ditto, Copstake, Lindsay, Crampton, & Co., warehousemen, basement and the contents slightly damaged by water, and the rest of the building and contents by smoke."

## Patent News.

THE following applications for Patents were made between December 27 and December 31, 1898:—

**LANTERN SLIDES.**—No. 27,352. "Improvements in and relating to Magic-lantern Pictures." R. J. W. DOWN.

**ORTHOCHROMATICS.**—No. 27,373. "Improved Means Applicable for Use in Orthochromatic Photography." R. W. ARLETT.

**OPTICAL LANTERNS.**—No. 27,448. "Improvements in Optical Lanterns and other Apparatus for Displaying Advertisements and other similar purposes." H. PIERPOINT.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

January.	Name of Society.	Subject.
16.....	Barnet and District .....	Lecture.
16.....	Bradford Photo. Society .....	Annual Meeting and Election of Officers.

19.....	Oldham .....	Velox Printing Papers. W. J. Belton.
20.....	Croydon Microscopical .....	Lecture: A Trip on the River Bure in Norfolk.
20.....	West London.....	Lantern Night: North country Life and Scenery. Edgar G. Lee.
21.....	South London .....	Annual Dinner.

### ROYAL PHOTOGRAPHIC SOCIETY.

JANUARY 10.—Ordinary Meeting, Captain W. de W. Abney, C.B., F.R.S., D.C.L., in the chair.

#### BUSINESS MATTERS.

A large number of candidates for membership were elected, and it was announced that nine members had been admitted as Fellows.

The CHAIRMAN stated that the following societies had been admitted to affiliation: Sefton Park Photographic Society, Hastings and St. Leonards Photographic Society, Yorkshire Philosophical Society (Photographic Section), Edinburgh Photographic Society.

#### ELECTION OF SCRUTINEERS.

The following members were elected to act as Scrutineers at the forthcoming election of Council and Officers: Messrs. J. Bulbeck, — Butt, E. Clifton, J. R. Gotz, W. B. Booker, E. Crofton, J. H. Agar Baugh, E. Sanger Shepherd, T. Sebastian Davis, R. Beckett, — Bennett, and H. C. Rapson.

#### THE LATENT IMAGE AND ITS DEVELOPMENT.

Mr. C. H. BOTHAMLEY, F.I.C., F.C.S., F.R.P.S., read "Some Remarks on Recent Papers concerning the Latent Image and its Development," in which he discussed in detail the recent paper of Messrs. Hurter & Driffield's latent image, Mr. Bothamley first expressed his surprise at their admission that the error of speed determination might be so large as thirty per cent. Alluding to their statement that their work indicated that, under certain circumstances, "the density ratios of the visible image cannot be said to be constant," he said that this clearly amounted to an admission that photographers had the power of altering the gradations by altering the mode of development, which was directly opposed to the original dictum, afterwards strongly emphasised, that the density ratios were unalterable. With regard to that part of the paper in which the thermo-chemistry of development was discussed, Mr. Bothamley called attention to the table showing the amounts of energy to be supplied in order to reduce halogen silver salts when certain alkalis were used, and said the conclusion arrived at, that on an average only three units of heat more were required when alkali carbonates were employed, than when caustic carbonates were used, was obviously incorrect. Caustic alkalis and alkali carbonates, when used in quantities proportional to their chemical equivalents, were equivalent only in their power of neutralising acids or displacing acid radicals from certain salts, and they were certainly not equivalent in reactions

of other kinds, including those occurring during development. Turning next to Messrs. Hurter & Driffield's main reasons for arriving at the conclusion that the action of light was not to produce a chemical decomposition of the silver bromide, but to bring it into a condition in which it was more amenable to the reducing action of the developer, the speaker criticised those reasons one by one in considerable detail, and endeavoured to show that there was nothing in the authors' observations which could be regarded as invalidating the ordinary chemical theory of the constitution and formation of the latent image, but that, on the contrary, they were in entire agreement with it. The chemical theory was defined as follows: The latent image consists of silver sub-bromide. When a plate is exposed to light, an extremely minute quantity of the silver bromide is converted into silver sub-bromide, the bromine which it loses combining with the gelatine that is in intimate association with the silver bromide in the emulsion; and it followed that the latent image was really a mixture of silver sub-bromide and bromised gelatine. In connexion with recent observations as to the possibility of developing an image on exposed plates from which all the silver bromide had apparently been removed by means of a fixing bath, Mr. Bothamley pointed out, after a full examination of the circumstances, that there was nothing in them to weaken the view which he held as to the chemical nature of the latent image, but that they actually strengthened that theory. He concluded a long and very exhaustive discourse by a consideration of Dr. Andersson's latest paper on the relation between the developing power of substances and their chemical constitution, criticising the validity of non-photographic methods of comparing the relative energies of different developers.

Mr. CHAPMAN JONES was rather in favour of the physical theory of the latent image, but at the same time there was no definite proof either way, and the facts might be as well explained on one hypothesis as the other.

Mr. W. E. DEBENHAM thought that the statement that the ratio of intensity could not be altered by development, which had been reiterated by many who were now convinced that it was a mistake, should be publicly withdrawn by them if they were convinced that it was erroneous.

Mr. J. CADETT favoured the physical theory of the action of light on the plate, and expressed himself as sceptical with regard to the existence of the sub-bromide of silver, which could not be produced by any ordinary chemical means.

The CHAIRMAN, owing to the lateness of the hour, closed the discussion with the remark that he would not enter into the question of the theory of the latent image, but that, if the physical theory were correct, there would be no need of sensitisers.

Mr. BOTHAMLEY then very briefly replied, and the proceedings were concluded by the passing of a hearty vote of thanks to him.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 5.—Mr. S. Herbert Fry in the chair.

Mr. PHILIP EVERITT repeated a number of questions put to him recently on optical matters: Whether it told against the working power of a lens in reducing as compared with copying same size? on roundness of field, depth of focus, &c.

The questions were such as to call forth the best debating powers of the members, and the matters at issue were fought out upon the blackboard with much earnest attention on the part of those possessing the necessary qualifications.

Mr. HADDON said that photographic lenses were not constructed in a manner to yield microscopic definition, and, when one came to reduce considerably with them beyond their defining power, the reproduction suffered. It was a question of the quality of the curves, but it was as well to know that one could not diminish as much as one liked and still get perfect definition.

Mr. PARFITT thought that, when working at a large size as compared with a small one, the advantage of a longer focus was obtained.

A question was asked by a member as to the solubility of ferric oxalate in water. One authority, he said, gave it as not soluble except with excess of oxalic acid, another worker said that it was very soluble, and a third gave it as soluble. The speaker now stated that it was one of the most soluble salts to be met with, and with this view Mr. HADDON concurred.

### PHOTOGRAPHIC CLUB.

JANUARY 4.—Mr. E. W. Parfitt in the chair.

A discussion took place on the advantages and disadvantages of toning chloride prints after fixing, as compared with the usual method, and as to the reason for the custom of toning prints before fixing.

The CHAIRMAN pointed out one obvious advantage of the less common method, namely, the fact that one need only tone to the depth which it was required that the print should possess when finished, seeing that there was no subsequent fixing action to interfere with the colour of the print.

Mr. W. R. STRETTON added that the tones, too, were more even in these prints toned after fixing. He made use of this variation of toning methods a great deal, and thought it curious that more people had not tried their hands upon it.

Mr. W. D. WELFORD said, however, that there was the disadvantage that it was much more difficult in practice than the universal method of toning prior to fixing.

Mr. A. MACKIE spoke of the platinum toning of chloride papers. Some papers did not lend themselves well to platinum alone, but he had got on such papers very pretty tones by treating them with a platinum toning bath for a time followed up by a gold bath.

Mr. WELFORD stated, in this connexion, that the Paget matt P.O.P. would tone to almost any colour within the platinum range with platinum alone. This was the only paper he knew of which he could say this.

Mr. FOXLEE, extending the scope of the question, said he preferred to stand

by albumen paper, and, failing that, collodio-chloride, rather than gelatine papers.

Mr. F. A. BRIDGER championed the cause of the albumen print. He thought that ideal prints on any paper, compared with a thoroughly good albumen print, would not approach the latter in excellence.

Mr. H. VIVIAN HYDE spoke of his experiences with persulphate of ammonia as a reducer. He had worked with it very successfully; it reduced the image in the high lights without affecting the shadow detail and half-tones, and was practically a local reducing agent. He and Mr. MACKIE spoke very favourably of this, the latest of MM. Lumière's production.

**Hackney Photographic Society.**—January 3, the President (Mr. E. Puttock) in the chair.—The meeting was occupied with a discussion on various subjects, in the course of which Mr. HENSLEY, referring to a recent recommendation to use amidol combined with pyro as a developer for under-exposures, said that he had recently tried it with great success. To 2 ounces of ordinary pyro-soda developer of half strength he had added about  $1\frac{1}{2}$  grains of amidol, plus a little sulphite of soda. This produced a very energetic developer, which seemed to get all possible detail out of a negative. The meeting closed with an exhibition of members' slides.

#### Leeds Camera Club.

##### EXPOSURE AND DEVELOPMENT

was the title of a lecture delivered on Wednesday, the 4th inst., by Mr. R. CHILD BAYLEY, editor of *Photography*. The lecturer drew attention at the outset to the need, which all science had, of a definite basis for accurate measurement if real progress were to be achieved. This held good in photography, as much as in astronomy or chemistry, and the want of some such basis had been early felt. After an historical sketch of the sensitometer and plate-speed measurement, a standard of sensitiveness being the point sought for, the lecturer described briefly the methods advocated by Claudet, Hunt, Vogel, Spurge, Warnerke, and others, and the researches in this direction of Captain Abney. The labours of Hurter & Driffield formed the principal feature of the lecture, an attempt being made to explain their definition of a perfect negative, and their method of speed determination and its results, without having recourse to mathematical language. Mr. Bayley showed, by means of sketches on the blackboard, how a certain subject produced different densities in the film of the negative, and how, if a correct representation of the subject on the resulting print was to be obtained, a correct exposure, as well as a correct development, was absolutely necessary, and, further, that it must be suitable to the printing process to be employed. A print should reflect to the eye an amount of light proportional to the amount reflected by the subject, and but one type of negative was capable of yielding a print which complied with that condition. In conclusion, Mr. Bayley said that, by using a standard light and a standard developer, a measured plate could be developed without being looked at to get a definite result, and for another batch of plates of a different factor of sensitiveness a proportional amount of exposure and development would yield practically identical results; and it was largely due to the researches of Messrs. Hurter & Driffield that these factors had been reduced to exact measurements. Photographers owed to them a debt in respect to the quality of the plates now obtainable that could never be over-appreciated.

**Sheffield Photographic Society.**—January 2, the President (Mr. Tomlinson) occupied the chair.—After the transaction of ordinary business and the election of a new member, a practical demonstration was given by Mr. W. J. BELTON on the new

#### VELOX PRINTING PAPER.

The lecturer commenced by explaining the various results obtainable by using papers varying both in surface and rapidity. A distinguished feature of the paper is that, whilst the half-tones are clearly rendered, there is no blocking up of the shadows; the image, being more on the surface, gives better definition, and is less mealy in appearance than other papers of a similar nature. One cause of failure, the lecturer explained, was not using the acid fixing bath, most amateurs using the plain hyposulphite of soda, which, after fixing a few prints, has a tendency to deteriorate those fixed subsequently. Any of the newer developers may be used, but a combination of metol and hydroquinone gives the best result, and must be three or four times the strength of that used for plates. Mr. Belton then proceeded to make prints from his own and from members' negatives, and, although the room was well lighted, all the manipulations were carried on in ordinary gaslight. The exposure is made to an ordinary gas burner, the time varying according to the colour and density of the negative. Development was effected by means of a brush, and so manipulated as to develop locally or otherwise, according to the result desired. Another prominent feature of Velox paper is that warm, cold, or red tones may be obtained by development or toning in the hot hypo or alum bath. Sample prints showing the various colours obtainable on the rough, glazed, and matt surface papers were shown, and handed round for inspection, and others exhibited on the walls called for general admiration. Some discussion ensued, after which a hearty vote of thanks was accorded Mr. Belton for his highly instructive and interesting demonstration.

#### FORTHCOMING EXHIBITIONS.

1899.

- January 25-31..... Perthshire Society of Natural Science. C. F. S. Burrows, Hon. Secretary, 16, Princes-street, Perth.  
 „ 30, 31..... Southsea Amateur. F. J. Mortimer, Cornwall House, Ordnance-row, Portsea.

- February 4-25..... Edinburgh Photographic Society. Hon. Secretary, J. S. McCulloch, 2, George-street, Edinburgh.  
 „ 13-18..... Photographic Society of Ireland. Hon. Secretary, 35, Dawson-street, Dublin.  
 „ 21-24..... Hastings and St. Leonards. Exhibition Secretary, A. Brooker, 21A, Wellington-place, Hastings.  
 March 4-11 ..... South London. Hon. Secretary, A. E. Allen, 27, Princes-square, Kennington Cross, S.E.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### STEREOSCOPIC PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—Mr. Penlake's remarks are always sensible and interesting, and I thoroughly agree with him that  $6\frac{1}{2} \times 4\frac{1}{2}$  (double quarter-plate) is on all accounts the best possible size for stereo work. Its great advantages have often been pointed out. For instance, we may use two quarter-plates, and thus save the trouble of cutting the negatives, or we may use a full-size plate when we desire one large picture. The  $6\frac{1}{2} \times 4\frac{1}{2}$  plate size has not those advantages, and for all-round work we do not gain much by using this size in preference to double-quarter plate. If we use  $6\frac{1}{2} \times 3\frac{1}{2}$  there is a difficulty in getting suitable plates everywhere, and, besides, the negatives require cutting in two. For the all-round worker who desires to combine lantern quarter and half-plates there is nothing better than  $6\frac{1}{2} \times 4\frac{1}{2}$ ; it is the ideal size, not too large to be awkward, not too small to be limited in its capacity for all-round work.

There is one great difficulty in the way of would-be workers with  $6\frac{1}{2} \times 4\frac{1}{2}$  size, and that is there are practically no manufacturers enterprising enough to make this one of their usual sizes, and it is very difficult to get either cameras or dark slides when required, though, from my knowledge of amateur photographers, most of them would prefer it to the present half-plate size, chiefly because of the facility in using quarter-plates at will as well as double quarter.

When using single quarter-plates it is well to put them in the slide in sheaths, as with the ordinary type of book from dark slides they are somewhat apt to slip behind each other.

The solid form of slide is, even for ordinary use, much neater than the old book-form type, and it is easier to fill and empty.

I am quite persuaded that the future is with stereoscopic photography. It will yet be used for ordinary illustrations.

Business firms will illustrate their catalogues stereoscopically, giving the customers practically the advantage of seeing the goods before buying them; ordinary flat illustrations are far from clear.

What disgusts people with stereoscopic pictures are the rubbishy one shilling per dozen slides that are sold, some of those that I have lately examined are atrocious. On the other hand nothing is more beautiful than a good stereoscopic transparency, carbon or otherwise.—I am, yours, &c.,  
 W. J. FARMER.

### THE ROYAL PHOTOGRAPHIC SOCIETY'S COUNCIL ELECTION.

To the Editors,

GENTLEMEN,—The typical professional photographer will feel flattered in reading Mr. G. T. Harris's letter to the *Journal* last week, and also perhaps wonder what opportunities this gentleman has of ascertaining "the frame of mind of the typical professional photographer towards the Royal Society;" but, when he proceeds to state that the professional's estimate of the value of a F.R.P.S. is limited to its commercial aspect, surely a protest is necessary.

A gentleman who must claim an intimate knowledge of professionals in order to write in the *Journal* the sentence—"This, without doubt, represents the frame of mind of the typical professional photographer," &c., should do something more to justify the assertion than quote the remarks of an individual, and can have no reason for adding, *Ab uno disce omnes*! There are men in every sphere of life undeserving the outward symbols of honour they sometimes obtain—hypocrites in the church, thieves in the law, quacks in medicine; but who would venture to say of members of these professions, "From one you may judge of the whole!"

It seems to be the mood among a certain small section of photographers to represent the professional generally, and the portraitist in particular, as an individual of sordid motives, and even devoid of the elementary intelligence necessary to photograph, say, a mudbank, or expose a plate in the twilight! Is it not time this petty nonsense should cease, and the largest and best side of the profession—and not the un-

important and the worst—be encouraged to make its influence felt both in the press and in our exhibitions?

No one, who has an eye to see, can fail to note with regret that our exhibitions give the public a painfully inadequate impression of the present position of professional photography. And why is this? In traversing the leading fashionable thoroughfares of London, and the larger provincial towns, whose windows seem to attract the great crowd?—those of the leading professional photographers? How many of these are represented in our exhibitions, and why so few? One may imagine a reason is the rejection by the Judges of work upon which the greater public has often pronounced a favourable opinion. Professional men have sometimes seen in past exhibitions that eccentricities, and the more or less "accidental" effects in photography have been better received by the Judges than the carefully thought-out, well-balanced, well-lighted work of the studio, and what wonder if of recent years they have accepted the inevitable, and stayed away?

No one will gainsay the great value and artistic influence of a certain section of amateur contributors to the exhibitions; but surely it is apparent that there is room for studio photography as well as the monologue on *Misty Mornings* and *Dying Days*.

Portraits are more than ever a photographic "power in the land." It is their work which gains universal notice, if we except perhaps the limited areas occupied by the photographic exhibitions.

It would therefore seem to the public interest that the professional should receive greater encouragement at the Society exhibitions and increased opportunities for comparison and the raising of that spirit of emulation so essential to all high endeavours, and the portraitist considers his special work makes the greatest demand on the skill of a photographer.

It is one thing to be a lover of nature, possessed of illimitable leisure, independent of monetary cares, and another to be a hard-worked professional, face to face with a great and exacting public—a public which demands instant evidence of artistic taste and tact and posing, allows no preliminary reveries, and seldom provides the picturesque element *ready-made*.

Probably the conditions which make for success as a professional and success as an exhibitor (under prevailing conditions) are not quite the same; but, if the commercial test is greatly at variance with the verdict of Exhibition Judges, does it not imply that the public are interested in much photography which our present arbiters care little about? And we have seen by the business careers of several men of exhibition fame that it has been easier for them to attain distinction at the exhibitions than to take an important position in the ranks of the professional workers they have subsequently joined.

If this is so, does it not prove that the professional requires special abilities, that these abilities are recognised in a practical way by the public? and, if so, why not by the Exhibition Judges?

Perhaps the forthcoming election may help to decide this question more equitably towards those members of the Royal who are not only attached to the Society for itself, but because it so largely represents the professional backbone of the country, and should control their special professional interests in the matter of its Exhibition. I am, yours, &c.,

Studio, 8, Regent's-terrace, Hull.

T. C. TURNER.

#### BUTLER'S SINGLE OR STEREOSCOPIC COLOUR CAMERA.

To the Editors.

GENTLEMEN,—My attention has been drawn to an article in your edition of December 30, giving a description of an instrument which is called "Butler's single or stereoscopic colour camera." I should be obliged if you would allow me to state in your valuable columns that this is an infringement of one of Mr. F. E. Ives's patents.—I am, yours, &c.,

THE PHOTO-CHROMOSCOPE SYNDICATE, LIMITED.

WILLIAM A. J. HICKES, Secretary.

Holbein House, 121, Shaftesbury avenue, London, W.C.,  
January 5, 1899.

#### THE ITALIAN EXHIBITION.

To the Editors.

GENTLEMEN,—Referring to my letter of 9th ult., which you kindly inserted in your paper, in which I called attention to the forthcoming International Exhibition of the Società Fotografica Italiana, I am now empowered definitely to inform you that the Society has decided on organizing an Invitation Section for British pictorial photography.

Within a few days the invitations will be issued to those selected to receive them, who I sincerely hope will contribute examples of their work, in order that the collection may prove a typical exposition of the progress and position of the British School. It is extremely desirable this should be so, for, strange to say, in Italy, the Home of Art, but little progress has been made in the direction which we have here taken. Our Italian friends express a very keen desire to have an opportunity of seeing and profiting by a representative collection of British work, and will, I am sure, appreciate not only the work itself, but also the goodwill of assisting contributors. I have arranged that all pictures sent in response to the special invitations shall be received in London, packed,

forwarded to Florence, and returned to London, free of expense to exhibitors.

The Special Section does not interfere in any way with the desires of those who wish to send exhibits to any of the other sections, a general programme of which has been distributed in the usual way.—I am, yours, &c.,

HENRY E. DAVIS.

Camera Club, Charing Cross-road, W.C., January 7, 1899.

#### PURIFICATION OF ACETYLENE.

To the Editors.

GENTLEMEN,—I notice in your issue of the 6th inst. you report that Dr. A. Frank has obtained a German patent for a process of purifying acetylene by a chemical mixture. I think it only fair to point out that Messrs. Thorn & Hoddle patented an apparatus, also a purifying material, which has been on the market over nine months. It does everything that Dr. Frank claims for his material.—I am, yours, &c.,

169, Southampton-street, Camberwell, S.E.

WILLIAM F. SLATER.

#### THE PHOTOGRAPHIC CLUB'S ANNUAL CONCERT AND LADIES' NIGHT.

To the Editors.

GENTLEMEN,—I have to inform you that our Annual Concert and Ladies' Night will be held on the 18th inst., when the musical portion of the entertainment will be entirely by professionals, and the whole under the direction of Mr. E. A. Newell.

Tickets will be forwarded to every member, and any remaining will be sent to those requiring them in the order of application to—Yours, &c.,

W. R. STRETTON, Hon. Secretary.

4, Queen-street-place, London, E.C., January 9, 1899.

#### SOUTHSEA AMATEUR PHOTOGRAPHIC SOCIETY'S ELEVENTH ANNUAL EXHIBITION.

To the Editors.

GENTLEMEN,—I shall be much obliged if you will kindly note in the columns of your next issue that the latest date for receiving exhibits in the open classes for amateurs and professionals in our forthcoming Exhibition is January 26.—I am, yours, &c.,

10, Ordnance-row, Portsea, Portsmouth. F. J. MORTIMER, Hon. Sec.

### Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

#### PHOTOGRAPHS REGISTERED:—

F. Holmes, Longleat, Warminster, Wilts.—Photograph of Longleat Winter Garden, Longleat, Wilts.

J. Smith, 4, Lansdown, Stroud, Glos.—Photograph of interior of St. Lawrence Church, Stroud, without dark shadow on altar.

E. H. SPAIGHT.—Much obliged for the suggestion. At present, however, it is impracticable.

F. E. R.—Send our publishers three prints and 1s. 7d., and they will effect registration for you.

A. Y.—Send our publishers three copies of each photograph, and one-and-sevenpence for each registration.

C. A. WAITE.—The address is Henry Gower, Photographic Copyright Union, London Chamber of Commerce, Botoolph House, Eastcheap, E.C.

E.M.S.—We regret we cannot tell you. The only suggestion we can make is that you advertise for some one to give you instruction in wax-modelling, and then adapt that to your requirements.

COLLOTYPE.—W. WALKER. "Where can I obtain full practical instructions for producing colotype pictures? Any information would greatly oblige, as I am quite ignorant in the matter."—At the Process School, B.Lit-court, Fleet-street, or at the Polytechnic, Regent-street, W.

STAINED NEGATIVES.—W. B. says: "A gelatine varnished negative with a platinum print on it got wet and badly stained. It was wiped over with weak acid (varnish not removed) and revarnished; this made things better, but the stain shows still. Would removing varnish altogether, treating with weak acid, now mend things?"—The only chance of getting rid of the stain is to remove both coats of the varnish, and then treat the film with acid, though we are not sure that it will now remove the stain. That treatment should have been resorted to at first.

**NERNST'S NEW ELECTRIC LIGHT.**—Rd. Smith says: "Can you inform me if Professor Nernst's new electric light is suitable for an alternating current?"—In reply: We are unable to supply any further information than that given in the paragraph. Some reader may, however, be able to help in the matter.

**G. W. S.**—Messrs. Dawbarn & Ward, 6, Farringdon-avenue, E.C., publish a little book on lantern-slide making by Mr. Coulthurst, and Messrs. Hazell, Watson, & Viney, Creed-lane, E.C., also have one by Mr. Hodges. These books do not treat of colouring, which you will find dealt with in Mr. Hepworth's *Book of the Lantern*, also published by Messrs. Hazell, we believe.

**W. ANDREWS.**—1. Messrs. Dawbarn & Ward, 6, Farringdon-avenue, E.C., will obtain the volume for you, price, we think, 2s. 2. We do not give the addresses of contributors. Send us a stamped, addressed letter and we will forward it to him. 3. We cannot spare space just now. Years ago the subject, now practically out of date in this country, was dealt with over and over again in the *JOURNAL* and *ALMANAC*, to back volumes of which we must refer you.

**STUDIO TROUBLES.**—INTEREST says: "Am much taken with article by Mr. F. Whaley on 'Studio Troubles' in *ALMANAC* for 1899, p. 778, but he is too brief for my dull comprehension. You will oblige by answering the following re above subject: 1. Is paper hung from all roof sash bars where twenty-four inches apart? 2. What width paper? 3. Is one edge fastened and the other allowed to hang vertical whole length of bar?"—In reply: 1. We should presume so from the article; it would certainly seem advisable. 2. The width of the sheet. 3. Yes.

**FORMULA.**—A. C. COLLIS says: "In going through your welcome Annual, I find, in 'Practical Notes and Suggestions of the Year,' a developer, viz.: Water, 1000 parts; pyrogallie acid, 28 parts; sulphite of soda, 350 parts; strongest sulphuric acid, 6 drops. For use, take 80 c. c. of solution and 80 c. c. of water, to which 8 c. c. of acetone had been added. I am in a fix. Will you, with your usual kindness, enlighten the ignorant, and give the above in ounces and grains, so that I can understand it? Thanking you in anticipation."—If you turn to page 638 of the *ALMANAC*, you will see a table of the French fluid measures and their equivalent in English ounces and drachms.

**MASKS; ACETYLENE.**—ARTHUR EDGAR asks: "1. Could you tell me where it would be possible to obtain masks similar to the enclosed? The print forwarded is produced from an American photograph. 2. Also, could you give me any instruction as to portraiture by the acetylene light; or, failing this, could you tell me where I could get such information?"—1. No, we cannot; but such masks are easily made by taking a negative of the frame against a tolerably dark background, and using that as the mask. The negative may be made on a celluloid film, and thus save double-printing. 2. Better write to Messrs. Thorne & Hoddle, Totill-street, S.W. They make a speciality of acetylene light for photography.

**EMULSIONS.**—H. B. If you follow out Abney's instructions, you should not fail to get what you require; but it must be borne in mind that plates equal to those now on the market cannot be expected to be made with a few dozen experiments. Their perfection has been arrived at only after years of constant practice and research. To answer all the six queries, and some of them are still vexed points, so as to be of practical value, would take up much more space than we can afford in this column. As we have just said, Follow the instructions given in Abney's book, and with more experience you will, doubtless, produce good plates, but do not work on too small a scale. A great deal appeared on gelatine emulsions in the volumes of the *JOURNAL*, 1879-1885. Almost every number contained something on the subject.

**TRAVELLING.**—VOYAGER asks: "Will you kindly state whether duties are exacted upon cameras carried into Italy by tourists? If you carry a camera and several dozen British or American plates, will there be inspection (i.e., opening), and will duty be charged? If so, what is the rate? Going into Switzerland, Germany, or France, is there a duty upon them? Which cities of Switzerland and France are likely to have dealers with stocks of fresh 6½×8½ and 5×4 plates?"—No duty is charged in any of the countries named. The plates will not be examined if they are duly labelled as photographic plates, which must not be exposed to light, and a polite intimation to that effect given verbally at the Custom-houses. The plates are stocked in all large towns, though, unless of English make, possibly not the exact sizes named.

**LENS—DEVELOPMENT—PRINTS.**—TADROUS HANNA (Egypt) asks: "1. How long must be the distance between Dallmeyer's stigmatic lens, series II. (patent) and the person for producing the largest cabinet but without exaggerating the perspective? 2. How long must be the distance between Dallmeyer's No. 2 a *carte-de-visite* or portrait lens (patent) and the person for producing the largest *carte-de-visite* bust without exaggerating the perspective? 3. Which is the highest degree of heat allowed to pyro-soda solution without making fog on the plate during development in summer? 4. I am obliged during summer to mount P.O.P. after drying. Is there any way for making prints dry straight and not hard, as when got out from printing frame? I used glycerine, but without good results."—In reply: 1 and 2. The stigmatic lens does not exaggerate the perspective, but, in common with all lenses, the nearer it is approached to the subject the more violent, yet true, is the perspective. From 12 to 20 feet from the sitter gives the most pleasing results. 3. It will entirely depend upon the character of the plates. Some will bear a much higher temperature than others; indeed, this varies even with different batches of the same brand of plates. 4. The best plan is to squeeze them down on to ferrotype or glass plate, previously treated with French chalk, when taken from the washing water, and allow them to dry on that.

**LENS.**—GOLFER says: "1. I have a lens which was sold to me as a Voigtlander Portrait, with rack and pinion, 4¼-inch diameter front lens 4 inch back, marked and numbered as per facsimile sketch. Who is the maker? 2. It is 20½ inch focus; the diaphragm opening is 2½-inch diameter. What is the U.S. number? 3. Could it not be made to work with a larger apparatus, and thus be made quicker? 4. Could it be made a shorter-focus lens by any means?"—1. The lens is not by Voigtlander, but of French make, though for the moment we do not remember who. It is of ancient date. 2. Roughly, f/8. 3. Probably the lens will not bear a larger aperture, as makers, as a rule, sand out their lenses with the largest aperture they will give good definition with. You might, however, remove the fixed diaphragm and see the effect. 4. No, except by reworking the glasses.

**PLATINOTYPE.**—C. O. & D. write: "In the course of a year I turn out some thousands of platinotypes for my employers, but I am greatly troubled by the meanness of the prints when finished, and, after having given the matter due consideration myself, I thought you might be able to help me out of my difficulty if I briefly set forth my method of working. Commencing with a fresh tube of the Platinotype Company's cold-bath paper, I cut up my paper to size, dry my indiarubber pad (which I place next to the paper) and my other pads and also the negative. Having exposed my paper, I take from my stock solution of oxalate developer (made up of 54 ozs. of water to 1 lb. of oxalate of potash) whatever I require for the day's work. I use it at a strength of 1 part oxalate to 3 parts water. I then pass my prints through this solution in the usual way, but, in spite of the utmost care, I get meanness in the prints more or less. At first I thought my pads were not dry enough, and I paid special attention in this direction. I have tried all practicable ways of making up my developer. The meanness appears directly the prints have passed through the solution, which I have tested for acid, and it shows no trace of it. I use my developer for cold bath at a temperature of about eighty degrees. Having told you this, you may be able to tell me something to remedy this great drawback to producing really good prints."—The only suggestion we can make is that the paper has been allowed to absorb moisture before it is printed.

**PLATINOTYPE.**—PRINTER writes: "Would you kindly answer the following? Have been most grateful for your help at other times. We use the Platinotype Company's A A paper, and several times on receiving a fresh batch of paper, or starting a new tube, we have been greatly annoyed to find lines running through, such as seen in coarse note paper. They appear during the printing, and sometimes disappear whilst developing, but at other times (perhaps the next print developed) showing very much all through, rendering the finished print useless. We have written to the Company, but they only remark it is bad development; but I have called my fellow-workmen's attention to these lines before the print is more than half off the negative, so that it cannot be overprinting that does it, and I don't know how the developer is at fault long before the print is anywhere near it. It is not dampness, as it is only with very fresh paper this happens. The Company also say, if we send them two or three undeveloped prints with the lines showing, they will develop them, to prove the defect can be remedied, but they don't send any instructions to help us in doing away with the defect. Can you advise us what to do? The lines run only one way in the cabinets, as the paper is cut to stretch lengthways, in cabinets the lines running horizontally through them, and the *cartes* are cabinets cut in two and turned round so as to stretch in width, the lines running from top to bottom. It is a great worry to me, and I do sincerely hope you will help me. The enclosed print is by no means the worst example I have had to deal with."—As the Company can avoid the lines in the development, no doubt, on a polite request, they will tell you how to do it.

**RELIEF PHOTOGRAPHY.**—W. A. G. says: "As several articles have lately appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY on photographic reliefs produced by gelatine and bichromate, one in the issue of the current week, I should be greatly obliged if you could tell me whether the process is open to the profession or not. I had been experimenting, and had produced a modification of my own which would, I believe, serve to turn out relief work (busts) at a moderate cost, when, chancing to look over THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1896, I saw, on page 844, an account of a patent which put a stop to further experiments. My idea was to make a plaster intaglio, as described, and use this as a mould, taking a reversed carbon print, produced by the simple transfer, pressing this into the mould, filling up with paper pulp, and allowing to dry in posit on. This is the outline, omitting details. The results of my rather rough attempts were certainly encouraging. I wish to know if I may work this and other similar processes, and whether my own process can be and is worth protecting? The black-and-white process mentioned twice lately in the *JOURNAL* is, I believe, unworkable, as the lamp-black compound does not bring out the picture, but simply effaces what was already there. I have tried the process several times, drying the print, as directed, as also partially drying it, which latter produced something a little more like a picture. While writing, I should like to ask why the new *ALMANAC* cannot be obtained through the booksellers at published price? I have had no difficulty till this Christmas."—In reply: The process, in our opinion, is quite open to the profession, notwithstanding the existence of several "patents," the validity of which, as we have before remarked, we strongly doubt. We doubt whether your own process is sufficiently novel to be patentable, at any rate we do not think it worth protecting. Send our publishers the name of the booksellers referred to, and they will inquire into your complaint.

\*. Several answers to correspondents unavoidably held over.

## EX CATHEDRÂ.

REFERRING to the correspondence at present appearing in our pages on the subject of the forthcoming election of the Royal Photographic Society's Council, we have been asked to give some indication, for the benefit of those residing at a distance from London, as to how a vote may be most advantageously cast. We do not think members can do better than vote for those of the old Council who stand for re-election. The outgoing executive is in thorough sympathy with the recently expressed desire of many to see the annual Exhibition conducted on broader lines than has recently been the case, and it would be wise of members to secure in this respect a continuity of policy, so that the desiderated improvement may assuredly take place.

\* \* \*

THESE remarks will serve to answer the esteemed correspondent who writes us: "I shall feel much obliged if you can let me know who are the men most likely to help the professional portraitist in the Exhibition question, because, after all, this is the keynote of interest among many members who are unable to attend the meetings. Last year's Exhibition

seemed to have gone to the dogs, it looked so painfully dreary; and it is really sad when one thinks and knows of the amount of good professional work which is being done all over the country. I believe there must be many members who, like myself, know next to nothing of the working of the Society, and who judge and value it only by results, without appreciating the inner causes. Can you not in some way indicate in THE BRITISH JOURNAL OF PHOTOGRAPHY (without giving offence) the lines upon which rival parties to office mean to run the Council. By some probable postal oversight or loss I have not yet received the *Journal* and ballot paper, or they may possibly enlighten me." The balloting paper is not yet issued.

\* \* \*

So far as we are aware, there are no "rival parties" seeking office. On the contrary, practical unanimity of feeling on most, if not all, points before the Society fortunately prevails. At the same time the remarks that have been made in our own pages and elsewhere with regard to the vital matter of the Society's Exhibition have, we believe, not been without a beneficial influence, and we quite expect to see next autumn that the "bread-and-butter" men will have a greater chance of showing their work than has lately been given them. Re-elect the old Council is our advice, failing the nomination of any persons obviously better fitted to conduct the Society's business. We hope our professional readers will avail themselves of their right of voting, and thus make their ideas felt in the matter.

\* \* \*

A MEETING of the Council of the Photographic Convention of the United Kingdom was held in London on Thursday, January 13. Mr. Martin J. Harding, whose labours on behalf of the Convention of the Shrewsbury meeting, of which he was local Hon. Secretary, will long be remembered with feelings of appreciation, was elected to fill a vacant seat on the Council. Dr. Hodges, representing the Gloucester Local Committee, was present at the meeting, before which a complete programme of the week's arrangements was laid. The principal excursions will be to Berkeley Castle on the Tuesday, Lord Fitzhardinge having very kindly granted members of the Convention exclusive privileges of photographing in the castle and grounds; on Thursday, a river trip on the Severn to Tewkesbury; and on Friday to Chepstow, Tintern, and Symond's Yat.

MEMBERS of the Convention will, we are sure, appreciate the alacrity with which Dr. Hodges and Mr. Dugdale (local Hon. Secretary) have got through the considerable preliminary labours incidental to the arrangement of the programme. The Mayor and Corporation have kindly consented to officially receive the Convention in the Guildhall, the large hall of which, capable of holding 700 persons, will be freely placed at the disposal of members during the week. The Bell Hotel will be headquarters. The Council appointed Mr. Sydney Keith to collect lantern slides for exhibition at the meetings, and Mr. Thomas Bedding was again deputed to secure papers for the evening meetings. The forward state of the arrangements justifies the expectation that the Gloucester meeting of the Convention will be very successful and enjoyable.

OUR contemporary, the *Daily Chronicle*, is responsible for the following remarkable story which, it adds, is agitating a section of society just now:—"A young lady of rank, who is engaged to be married to an officer serving in India, recently had her photograph taken by a leading London photographer before going out to India to be married. To her horror, when the photographs were sent home, there was plainly to be seen standing behind her, in a very menacing attitude, the phantom image of her *fiancé*! The young lady was photographed no less than three times, under apparently ordinary circumstances, but each time the same form is said to have appeared on the negative. The prospective bride has postponed her departure until inquiries can be made regarding this singular affair." We have read something not unlike this before. The supplementary figures, it is true, are usually alleged to be those of dead persons, but here the mysterious visitant is a living individual. In this respect, therefore, the story differs from the "usual thing" of the sort. It is noteworthy that these remarkable occurrences are seldom supported by such not altogether irrelevant details as dates, names of persons and places, and so forth.

MR. S. H. R. SALMON has sent to *Nature* a series of slides which, our contemporary says, are of great interest, since they appear to represent portions of lunar landscapes, and are astonishingly like the real photographs of them. "In fact, among all artificial methods of trying to produce lunar effects without the intervention of any hand work this is, as far as we know, the most successful. The process Mr. Salmon employs is very simple, and can be easily repeated by any one. It is only necessary to smear a little paste on to a glass slide, and gently warm it from below with a spirit lamp until it is dry. Observing it then with a microscope, we are confronted with this lunar-like appearance. The slides which we have before us represent many variations of lunar formations. In this one we see a small craterlet on the wall of a large crater, while in another we have rills widening now and again into craterlets. In a third slide we have a large crater, very like some on the moon, showing beautifully the gradation of tone on the surrounding wall. All the markings are, as Mr. Salmon states, perfectly accidental, and can be seen with the microscope."

MR. H. WALTER BARNETT, of 1, Park-side, Hyde Park Corner, S.W., writes us: "I send for your perusal the enclosed

wonderful composition, received by me to-day, and which, I think deserves a prominent notice in your widely read JOURNAL. I think you will agree that it is a highly humorous composition, and no doubt the author is delighted with his effort. The card from Paris came to hand a few days ago. It seems as though these would-be educators are inspired to do their deeds of glory by the evident success of the 'notorious M. Tanqueray' of free-portrait fame. In the interests of suffering British photography will you not raise your hand against these things?"

THE first of the curious productions to which Mr. Barnett refers comes from Bohemia, and is as follows:—"180 Splendid Attitudes. A photograph, should it produce an agreeable impression and please to all, must show the figure's posture unaffected and natural, suitable to the age and profession. Each photographer has not leisure and occasion to apply studies to this effect, and there are therefore photos which cannot pretend to be artistical. To meet this inconvenience, I have arranged from originals of renowned artists and from portraits of my own make a collection of 180 elegant attitudes, comprising pleasant motives and ingenious ideas. These 180 models are reproduced upon 20 tables, 9 upon each. They are most distinctly finished and sufficiently sized, so that photos made according to them have a surprising success. This collection contains charming attitudes of children, half and full-length portraits and groups, nudities and costumes being excluded. A complete collection of 20 tables (180 postures) is offered at the price of  $\frac{1}{2}$  £ only, and will be sent free if payment is effected in advance or against reimbursement. A specimen sent on demand free, if a five-pence stamp is enclosed."

The other, which comes from Paris, runs in the following terms:—"Art Studies. New ideas and effects in lighting, posing, and arrangement. Cabinets from the leading Parisian studios specially selected."

If any of our readers have received any of the specimens, we shall be glad to know their nature. The circulars are probably being distributed broadcast.

At a meeting of the Pharmaceutical Society, on Wednesday, January 11, the following were adopted as regulations for the keeping, dispensing, and selling of poisons within the meaning of the Pharmacy Act, 1868, in accordance with the provisions set forth in Section I. of the Pharmacy Act, 1868:—

1. That, in the keeping of poisons, each bottle, vessel, box, or package containing a poison be labelled with the name of the article, and also with some distinctive mark indicating that it contains poison.

2. Also that in the keeping of poisons each poison be kept on one or other of the following systems, viz.:—(a) in a bottle or vessel tied over, capped, locked, or otherwise secured in a manner different from that in which bottles or vessels containing ordinary articles are secured in the same warehouse, shop, or dispensary; or (b) in a bottle or vessel rendered distinguishable by touch from the bottles or vessels in which ordinary articles are kept in the same warehouse, shop, or dispensary; or (c) in a bottle, vessel, box, or package kept in a room or cupboard set apart for dangerous articles.

3. That, in the dispensing and selling of poisons, all liniments, embrocations, and lotions containing poisons be sent out in bottles rendered distinguishable by touch from ordinary medicine bottles, and that there also be affixed to each such bottle (in addition to the name of the article, and to any particular instructions for its use) a label giving notice that the contents of the bottle are not to be taken internally.

\* \* \*

FROM a communication that has reached us we are pleased to learn that our at-one-time excellent contemporary, the *American Journal of Photography*, which suspended publication at the beginning of the year, is to reappear forthwith. It will be conducted and published by Mr. Austin C. Leeds, of Philadelphia, while the editorial department will continue under the direction of Mr. John Bartlett. The management is independent of all controlling trade influence. It is announced that neither labour nor reasonable expense will be spared to secure whatever is of value—scientific, technic, mechanic, and artistic—to the expert or beginner. Recognising the importance of illustration, every effort will be made to render the *American Journal* pictorially interesting, and all the improved resources of photo-engraving and chromo-photography will be liberally made use of. It will be issued on the 15th of each month, and will contain forty-eight pages of articles. We wish our resuscitated contemporary success. There is great scope for independent photographic journalism in the States.

#### MODERN FALLACIES REGARDING ANCIENT METHODS AND PROCESSES.

PHOTOGRAPHY, this year, reaches the age of sixty, and the progress it has made during that period needs no comment whatever. The number of the old workers of the earlier processes and methods, unfortunately get fewer and fewer year by year; therefore, at the present ages, it is necessary that for the benefit of future generations the older methods of working should be correctly described when referred to, and not misrepresented, otherwise they will become misleading in the future.

Unfortunately, there is a propensity with some writers of the present day to commit themselves to print on subjects on which they are totally ignorant, and thus promulgate unwittingly fallacies that years hence may be quoted as facts. For example, we saw in a contemporary some time ago that a contributor described the Daguerreotype as an image on a silver plate "intensified with the bichloride of mercury." So far as we remember, this absurd description passed quite unchallenged, and thus at some future time may perhaps be quoted as a fact; who knows? If such things pass at the present time, what may not be expected in the next generation, if histories of photography are compiled, and such descriptions are utilised?

One very prominent fallacy amongst some at the present time is that the calotype and the waxed-paper processes are one and the same, for we frequently see written the "calotype or wax-paper process" when referring to paper negatives of the past, and we know that at one of the recent historical exhibitions some old calotype negatives were sent by their

present owners as being wax-paper ones. The error was, however, seen by the organizers, and the prints were shown under a right description. The calotype and the wax-paper processes are quite distinct from each other—quite as distinct in every way as are the wet and dry-collodion processes; in fact, the dissimilarity is really analogous. In the calotype process the paper is exposed wet, with the free nitrate of silver of the sensitiser upon it, and it has to be exposed within a short time of its preparation. In the waxed-paper process the free nitrate of silver was washed away, and the paper was dried before exposure, also paper could be kept for months after preparation. The former was a rapid process, while the latter was an exceedingly slow one; in fact, the conditions were quite analogous to those obtaining in the collodion processes, wet and dry. In the former of these the plates were exposed wet with the free nitrate of silver upon them, and were very sensitive. In the latter the free nitrate was washed off, and the plates could be kept for a long time, but they were then very slow. With this explanation it will be seen how fallacious it is to describe the calotype and the waxed-paper processes as if they were one and the same; also how misleading it may be to historians of the future.

Here is another fallacy that one sometimes sees in print, particularly since the "combined bath" has come into use for modern papers. In contemporary as well as in our own columns, though we have frequently pointed out the wide difference between the two, writers have assumed that the old sel-d'or and the old combined fixing and toning baths are one and the same. Only a fortnight ago, Mr. J. Pike, in suggestions to a correspondent for obtaining sepia tones on wet-collodion slides, says: "Of course, 'Colonial' has tried the usual toning solutions and the old sel-d'or combined toning and fixing bath." In saying this he was clearly unaware that there is just the same difference between the sel-d'or toning bath and the old combined toning and fixing bath as there is between the modern sulphocyanide toning bath and the modern combined bath method of toning and fixing. The sel-d'or, like the sulphocyanide, is simply a toning bath, and nothing more, the fixing being an after and separate operation.

Sel d'or—salt of gold—it may be explained, is a double salt of hyposulphite of gold and soda, containing one atom of the former salt to three of the latter, with four atoms of water of crystallisation. It forms needle-shaped crystals, and used to be sold in sealed tubes or bottles containing thirty or sixty grains each, as chloride of gold is now put up for sale. The favourite brand at that time was that of Fordos and Gelis, and it was first used for toning Daguerreotypes. The toning bath for paper prints—the ammonio-nitrate, or plain salted, it was not suited for albumenised—was made by dissolving the salt in the proportion of four grains to each eight ounces of water, and then slightly acidifying the solution with hydrochloric acid. The bath was then ready for use. After toning, the prints had, of course, to be fixed in a solution of hyposulphite of soda, and of the same strength as modern ones toned with the sulphocyanide bath have to be. Sometimes, instead of employing the commercial crystallised salt, an extemporary sel-d'or bath, made as follows, was used:—Chloride of gold, 1 grain; hyposulphite of soda, 3 grains; hydrochloric acid, 4 minims; water, 4 ounces; the fixing of the prints being the same, as a matter of course, as when the crystallised salt was used.

Why two old methods of working so widely different should ever have become confounded as being one and the same it is difficult to conceive. Possibly, however, it may have arisen, in the first instance, from the fallacy of a single writer, ignorant of his subject, and perpetrated by others since. Whatever be the reason, it, however, proves that fallacy promulgated at the present time may be accepted as facts in the future. So much the worse for the true history of photography in the future.

**Extra-fine Ground Glass.**—M. Beans suggests the following method of making extremely fine ground glass: A 4.5 per cent. solution of gelatine is prepared, to which from 3 to 6 per cent. of potassium fluoride is added, and, with this, coat the sheet of glass of the required size; allow to dry thoroughly, and then immerse for thirty seconds in a mixture of hydrochloric acid 1 part, water 30 parts, and then place in a flat position to dry. When thoroughly dry, strip off the gelatine, and the glass will be found to have an extremely fine matt surface.

**A Half-tone Process for Aluminium or Zinc Printing.**—Professor Aug. Albert suggests the following process in the *Photographische Correspondenz*. A rather finely grained collotype plate is rolled up with black ink with which is mixed some transfer ink, and as soon as a satisfactory result is obtained a pull is made, not on paper, but on a fine-grained aluminium or zinc plate, which takes the ink very well, especially if a little more pressure is put on the machine. By this transfer of the continuous tone image to the grained metal surface an image is obtained which can be used for ordinary printing, if the further treatment is the same as an ordinary transfer or chalk drawing of the lithographer, with the exception of the strengthening of the transfer by means of ink. Before etching, any of the ordinary litho processes, such as touching up with chalk, needle, &c., or another transfer of writing may be done, and the process may be used for colour printing, placards, &c.

**Röntgen Rays in Military Surgery.**—Major Battersby lectured on this subject before the last meeting of the Röntgen Society. He was selected for service in charge of the Röntgen ray apparatus in the Soudan, where the temperature varied from 100° to 122° F. in the shade; and his paper was based upon his experience in this campaign. After the battle of Omdurman 121 British wounded were conveyed to the surgical hospital at Abadieh. Of that number there were 21 cases in which the bullet could not be found or its absence proved by ordinary methods. In 20 out of these 21 cases an accurate diagnosis was arrived at with the help of the rays, the odd case, who was suffering from a severe bullet wound in the lung, being too ill for examination at the time. The senior medical officer in charge of the hospital said: "The Röntgen rays proved of invaluable assistance in localising the exact position of bullets, and in many cases rendered probing of wounds unnecessary. . . . In many cases the X rays prevented much suffering to the patient, which would have been caused by probing, the use of the finger, or enlarging the wound in the ordinary search for the bullets, as the skiagraph at once indicated the exact position of the bullet. In other more complicated cases the Mackenzie-Davidson method localised the exact position of the bullet, so that the surgeon was at once able to come to the conclusion if operative interference was judicious or otherwise. If considered advisable, the removal of the bullet was much facilitated by the diagram previously indicating exactly where the projectile was to be found."

**The Recent Eclipse of the Moon.**—According to an American contemporary, the total eclipse of the moon on December 27 was viewed with considerable success at the United States Naval Observatory at Washington. Owing to partial cloudiness, several of the occultations could not be observed. The moon was scheduled

to enter the shadow at 4.57 o'clock, and the totality to begin exactly one hour later. The actual time was a few seconds later. According to the arrangement made by the Observatory at Pulkowa, Russia, one hundred-and-three occultations were to be observed in different parts of the world, and twenty-one were assigned to the National Observatory at Washington. Seventeen of the twenty-one occultations were observed, and the rest were obscured by clouds. The scientific value of the eclipse will be chiefly verifying the knowledge which has already been obtained by other methods regarding the same diameter of the moon. Observations were also made at New Haven, Conn., at Columbia, by Professor Rees, and at Princeton, N. J., by Professor Young. The eclipse was viewed with great success in Berlin at the Treptow Observatory by Professor Archenhold, who photographed it in all its phases. At Berlin the moon entered into totality at a quarter to twelve o'clock, when the colours became brighter than previously. It was first a dark brown with a streak of yellow; next a reddish brown; and lastly a beautiful combination of colours, as though pierced by the rays of the sun. The silver-white line then kept spreading, and at twenty-five minutes past twelve it was at the maximum. In every phase the delineation of the moon was visible; that of the shadow of the earth was much less clear. It is stated that Mars became very red during the period, becoming more intense according to the colour assumed by the earth's shadows.

**Spectrum of a Radio-active Substance.**—In *Comptes Rendus* M. E. Demarcay states that M. and Mme. Curie asked him to examine, spectroscopically, a substance consisting chiefly of barium chloride, but supposed by them to contain also a new element. The material was dissolved in distilled water, slightly acidulated with hydrochloric acid. The spark spectrum of this solution was very brilliant. He photographed the spectrum, having prepared two plates, and giving one double the time of exposure of the other. These two plates gave practically identical results. He measured the lines, and was able to see: (1) barium, with great intensity of both the strong and weak lines; (2) lead, recognised by its principal lines, which were much more feeble than the others; (3) platinum, due to the electrodes and traces of calcium probably from the solvent; (4) a line, stronger than the weak lines of barium, with wave-length 3814.8 (Rowland's scale). This line does not appear to have been attributed to any known element, and is probably due to a new substance, for two reasons; firstly, that on the plate were no lines, other than these enumerated, except a few feeble air lines, thus excluding the presence of all elements having only weak lines in the neighbourhood of 3814; secondly, the methods employed for the purification of the substance prevent the possibility of the presence of iron, chromium, cobalt, or nickel, &c. Barium and lead, M. Demarcay is fully assured, give no line coinciding with this. This line has been measured by means of the two platinum lines, 3818.9 and 3801.5, which enclose it. It is near to, and distinct from, a bismuth line of moderate intensity. His conclusion is that the presence of the line 3814.8 confirms the existence of a small quantity of a new element in M. and Mme. Curie's barium chloride.

#### JOTTINGS.

THAT eminent man of science, Mr. J. W. Bennetto, who is undergoing so much local and metropolitan persecution because, having discovered the secret of colour photography, he refuses to divulge it to a world that would infallibly rob him of the profit and honour of his invention, may take comfort in his hour of trial. He is not the first great discoverer who has had to suffer for his success. Galileo was imprisoned for his astronomical theories, and only three years ago Röntgen was laughed at for days by ignorant newspaper writers for alleging that solid bodies were penetrable by luminous radiations. Yet time has vindicated both the great astronomer and the great physicist. Time, too, may be relied upon to vindicate Bennetto, the first man of science to solve the hitherto insoluble problem of colour photography. So let the Philosopher of Newquay have courage! He is assured of an immortal renown and a bust in Westminster Abbey.

It is true that, unlike Galileo and Röntgen, Bennetto prefers not to indicate the exact nature of his discovery; but such reticence, instead of exposing its gifted author to the ridicule of the profane, should, I submit, rather be accepted as a sign of the modesty and confidence which we naturally look for in a successful man of science. It is only such inferior and unscientific persons as Ives, Lippmann, and Joly, who publicly descend to details, and tell you precisely what they claim, and how they produce their results, not forgetting, of course, the illustrious and philanthropic M. Chassagne, who actually sent some of his pupils to England from Paris for the purpose of publicly demonstrating his memorable selective absorption process. But look at the penalty of such frankness! When the calm, uncommunicative, successful discoverer like Bennetto arises, with the philosopher's stone of colour photography safe in his pocket, he is enabled to regard with pity and contempt the abortive efforts of Philadelphia experimentalists and French and Irish professors. What do *they* know of colour photography, forsooth?

Yes, give me science at all costs, especially in colour photography. What can be more admirable in a man of science than a sturdy and dauntless indifference to the failures of those who have preceded him in a particular line of work? Mr. Bennetto finely exemplifies this characteristic trait of the thorough-going investigator in his process of colour photography, which was published last month. It is true that this process, shortly describable as trichromatic negative-taking plus bichromate-printing in coloured pigments, was invented, tried, and abandoned as comparatively useless years ago. But what of that? Does it not prove that, in going to the ancients as the source of his knowledge, Mr. Bennetto is animated by the yearning to escape from the influences of the sham or superficial science which is only too prevalent in these days? does it not prove boldness of theory, originality of practice, and a firm disregard of the opinion of those shallow and misguided individuals who only discern supreme merit in absolutely new ideas, and are inclined to view with disfavour the exhumation of dead and buried processes? Undoubtedly it does. So, Mr. Bennetto, sir, I salute you!

Stereoscopic photography appears to be exciting renewed attention just now, and there have been several letters and articles published in these pages relative to the most suitable size of plate to use. The double quarter, or half a whole-plate ( $6\frac{1}{2} \times 4\frac{1}{2}$ ), has many advocates, myself among them, but I wish those writers who choose the size because it allows of the use of two quarter-plates when  $6\frac{1}{2} \times 4\frac{1}{2}$  plates are not obtainable would try the idea before wasting ink upon it. More nuisance than its worth is an estimate that here applies with great force. Two quarter-plates set side by side in a dark slide are displaced on the smallest provocation, so that you are never sure of your exposures having been properly made, and in transparency-making from the negatives—if you have been fortunate enough to obtain them—the trap into which one is likely to fall, by having to handle two plates, is obvious. Working in the dark, and exposing in contact, you want all your wits about you to keep your lefts and rights right with *one* plate; but, when you come to two, you must redouble your care. By all means let us have the very elegant and symmetrical size,  $6\frac{1}{2} \times 4\frac{1}{2}$  (the true half-plate), but let us get rid of the stupid notion, repeated from year to year by imitative new comers, that “two quarter-plates” may conveniently be used instead of the single half-plate. The care so necessitated makes stereoscopic photography a burden instead of a pleasure.

It is late in the day to descant upon the charms of stereography. The individual who cannot appreciate a properly prepared binocular photograph is to be pitied. But it is not too late to repeat an old suggestion of mine, that professional photographers should try to popularise stereoscopic portraiture, studio and “at home,” especially the last, amongst their sitters. The old timers, no doubt, will smile at the suggestion; but I have faith that the younger men who are coming on in photography will at least have the wit to take all seriously tendered suggestions into consideration, a respect in which

the old timers are not notorious for having been successful. If in the photographer's reception-room there were placed a few stereoscopes with slides and transparencies of people amid suitable accessories, or among home surroundings, many a sitter might be induced to have him or herself binocularly portrayed. If the centres of the show stereographs are well under 3 inches, say  $2\frac{1}{2}$  inches, or even a shade less, the readiness with which the magic effect is obtained will materially help the photographer in his object. The difficulty people have of seeing stereoscopic photographs stereoscopically is, in the great majority of cases, due to the excessive separation of the centres. This I have found to be so in scores of instances that have come under my own personal observation.

Yorkshire, having brought off one of the most successful photographic exhibitions yet held, is setting about the formation of a Union of photographic societies having their homes in the county of many acres. There are about twenty of these societies, or nearly a tenth of the total number in Great Britain. But, besides societies, “photographers” are to be included in the Union. Does this mean isolated individuals, not members of any society? Practically the Yorkshire men wish to do for themselves what the Affiliation has hitherto done for them. Such a movement as this was inevitable sooner or later. I should not be surprised to see other powerful photographic centres like Glasgow, Edinburgh, Liverpool, and Manchester, and Birmingham follow suit. I take it that a desire for a kind of photographic Home Rule is at the bottom of the idea. Local spirit is bound to assert itself in the long run when hundreds of miles separate a constituency from the seat of government.

This brings me to the subject of the Royal Photographic Society's Council election and the letter of Mr. G. T. Harris published on January 6. That letter is an able and academical defence of things as they are, which might have been officially penned. Its obvious defect is its lack of sympathy with the aspirations of large numbers of professional photographers who look to the Royal Photographic Society to help them in their legitimate strivings after improvement. It cannot be denied that recent exhibitions at Pall Mall have prevented many able men from profiting by the opportunity of exhibiting their work—men of the stamp of those who aforesaid were the mainstay of the Exhibition. According to Mr. Harris such men have no more interest in the Society than the merest outsider or the *dilettante* person who can afford to pay twenty-one shillings a year! And it is their own fault that they do not go to the meetings, the highly abstruse discussions at which Mr. Harris thinks suitable pabulum for all tastes and requirements! Nobody, of course, expects the Royal Photographic Society to exist for professional photographers only, or to relinquish its work in the advancement of science. Nobody wants it to be a benefit society or a trade centre; but, on the other hand, all but a few persons cannot fail to see that the Society by no means takes the fullest advantage of its scope and opportunities, and has vast and unexplored fields of work before it.

Mr. Harris asks what the typical professional photographer expects of the Society. The President (Lord Crawford) answered the question, by anticipation, last autumn, when he told the Society that it was neglecting the “bread-and-butter” side of photography at the exhibitions. The fact is that, as the leading photographic society in Great Britain, a variety of interests are committed to the care of the R.P.S., and in recent years not all of those interests have been studied. How many people realise that in Great Britain there are between 4000 and 5000 professional photographers? How many of these are members of the R.P.S.? I have dreamed that one day the elevation of the status of professional photography will be an accomplished fact; that the R.P.S. will occupy a relationship towards professional men such as the Colleges of Physicians and Surgeons, the Institution of Civil Engineers, and the Institute of Architects hold towards members of the respective professions they represent. Am I to suppose that Mr. Harris and his friends do not wish such a consummation? It is not impossible of achievement and I for one hope to see it accomplished.

Remembering that the R.P.S. is one of the few "Royal" Societies and has a charter, is it not remarkable that anybody with a guinea in his pocket can become a member? Surely such a state of things will not be allowed to continue long. Members recruited from a source of this nature can hardly be regarded as capable of contributing real strength to a society. The "bread-and-butter" man holds aloof in his thousands because no special effort is made to attract him, as is done in the case of the Pharmaceutical and many other representative societies. I am convinced that, without abdicating in the least its mission to advance the interests of photographic science, or stepping outside the lines of its charter, the R.P.S. has it in its power to become a mighty representative body, entitled to speak and act on behalf of thousands of men who have a stake in photography. But such letters as that of Mr. Harris, and the narrow-minded view of what the Society should be which several other persons take, will not assist the forward movement.

Of course, Mr. Harris and others have a perfect right to urge that the Society shall keep to the lines upon which it was originally started—that of a scientific debating society—nothing more; but to insist upon the point is equivalent to an admission that much which has been done by the Society in recent years was needless and wasteful. Surely rooms in Great Russell-street and Hanover-square, an efficient secretarial staff, the Charter, the Fellowship scheme, the Crystal Palace Exhibition, and the house in Russell-square—surely this highly elaborated machinery were superfluous in the case of a society whose sole *raison-d'être* is, to quote Mr. Harris, "discussions." I prefer to take the broader view and to look upon these things as so many marks of progress along the path that leads to the consummation of an "Imperial" policy, to quote my friends of the *Photogram*, and that will be when no photographer worthy the name is outside the R.P.S., and when it will be to the direct interest of every "bread-and-butter" man to seek membership and be proud of it.

COSMOS.

#### FOREIGN NEWS AND NOTES.

**Cyanine as a Sensitizer.**—Baron von Hübl draws attention, in the *Atelier des Photographen*, to various properties of cyanine which may account for the difficulties frequently experienced in using this dye. A peculiarity which has received little notice is the insolubility of cyanine in water and dilute alcohol. An alcoholic solution of cyanine diluted with much water has a violet-blue colour. A superficial observer might take this to be a solution of the dye, but it is in such a condition that, if passed through stout filter paper, the liquid becomes colourless, and the dye remains upon the filter. Such a bath would not dye the inner part of the film of a dry plate, and the cyanine retained upon the surface of the film would probably cause fog and spots. The sensitising bath should consequently contain abundance of alcohol. The colourless acid combinations of cyanine readily dissolve in water, and this accounts for the powerful action of the sensitising bath made up with acetic acid as recommended by Weissenberger, who discharges the colour of the bath by adding a few drops of acetic acid, thus producing an acid combination soluble in water. This bath penetrates the film, and the blue dye is thus deposited below the surface when the plate is dried, the combination of acetic acid and cyanine being only possible in solution. Another peculiarity of cyanine is its instability when dissolved in alcohol. Dr. Eder has recommended the treatment of commercial cyanine with concentrated hydrochloric acid and subsequent evaporation to dryness. The dye will then give plucky negatives free from fog. It is a common opinion that the iodide is thus converted to chloride, and that a more suitable preparation is obtained, but, if commercial cyanin is rubbed down with moist chloride of silver and treated with alcohol, the bath will still give foggy negatives devoid of vigour.

The improvement due to treatment with hydrochloric acid must, therefore, have some other cause, which is probably the removal of foreign substances by the acid from the commercial article, or conversion of a portion of the cyanine into colourless soluble substances. The fact that a resinous precipitate is left after treatment of cyanine with concentrated hydrochloric acid supports this view. Unfortunately, cyanine thus treated deteriorates rapidly. In a week a loss of sensitising power is frequently observable, and, as the solution gets older, the plates lose sensitiveness in increasing

degree. The deterioration of the solution proceeds much more rapidly in daylight, and exposure to sunlight for half an hour reduces the sensitising power to about one-fourth. The following rules may be deduced from these facts:—

1. The solution must contain a considerable quantity of alcohol, say about thirty per cent.

2. A minimum of the dye should be used. 2 c. c. of cyanine solution of the strength of 1 in 500 are sufficient for a bath of 200 to 400 c. c.

3. The solution of the dye should be freshly prepared and protected from light.

As cyanine loses its colour in the presence of weak acids, an alkali should be added to the bath. Usually a few drops of ammonia are added; but a solution of borax is preferable, as it renders the plates permanently alkaline, and prevents any change in their condition, even after they are dried. If fine definition is unimportant, the plates may be exposed wet. In the dry state, however, the plates are less sensitive, and have a tendency to fog. If it is necessary to dry the plates, dextrine should be added to the bath. Baron von Hübl recommends the following baths:—

#### SOLUTION A.

Ten per cent. solution of dextrine in water .. 400 c. c.  
Alcohol ..... 150 "  
Cold saturated solution of borax ..... 20 "

For orange sensitive plates, as used in three-colour work for the blue picture, take 300 c. c. of Solution A,

2 c. c. of cyanine solution (1 in 500).

If the plates should also be sensitive to green, add to this bath 2 c. c. of chinolin red solution, 1 in 500, or ammoniacal solution of eosine silver, preferable 3 c. c. of Dr. Albert's P dye. To secure sensitiveness to blue green also, 4 c. c. of acridine yellow (1 in 150) should likewise be added. Plates thus prepared may be used for three-colour work and with Joly's screens. The plates are left in the bath from five to ten minutes, and dried in absolute darkness, without previous washing. If the plates are exposed wet, water may be substituted for the dextrine solution.

**Another Giant Telescope.**—The *Photographische Mittheilungen* states that the new telescope for the Potsdam Observatory will be ready by July 1 next. The dome of the observatory is finished, and the stand for the telescope is now being constructed. The tube of the telescope is 32 feet long, and there are to be two objectives, 50 c. and 1 m. in diameter. The latter is for stellar photography. Both lenses are being made by Messrs. C. A. Steinheil Söhne, of Munich, and their joint weight is about 13 cwt.

**The Pyro-acetone Developer.**—The same journal mentions that this developer is particularly suitable for plates with a tendency to frill. Although it has been stated that acetone in use is not superior to carbonate of soda, yet it must be remembered that the former is of great value for the development of plates that show the imperfection we have mentioned. A batch of plates, which frilled very badly with the pyro-soda developer, was quite under control with pyro acetone.

**A New Lens.**—A few months ago we mentioned that the firm of Carl Zeiss had constructed a new lens, by means of which an object could be photographed in exaggerated length or breadth. The lens may become important for the alteration of designs in the manufacture of carpets, &c. The *Deutsche Photographen Zeitung* has just published as a supplement two pictures showing how the lens may be used by the photographer for taking caricature portraits. Two men are engaged in earnest conversation. One has a white hat, black coat, white trousers, and striped waistcoat, and the other a black hat, white coat, striped trousers, and an umbrella. In one picture the men are tall and thin, and in the other short and fat. The effect is very ludicrous, and, as the identity of the individuals is strictly preserved by the lens, the photographs are far in advance of any we have seen produced by means of artificial backgrounds.

**Sunday Observance.**—The recent laws enacted in Germany for the observance of Sunday rest seem to have produced some friction, and many photographers consider them a grievance. A merchant recently applied to a customer on a Sunday for settlement of an account. A complaint was lodged against him for non-observance of the police regulations, and he was condemned. He has,

however, successfully appealed against the decision, which has been quashed upon the ground, that working in public consists of such acts only as would appear to be work in its general acceptance.

**Ebonite Shutters.**—Dr. Paul Michaelis mentions in the *Rundschau* that he noticed, during a Norwegian trip, discharges of electric light in drawing the ebonite shutters of his dark slides. The ebonite was in contact with aluminium, and by increasing the friction the electrical discharges were intensified; fortunately the plates were not affected. The experiment was again tried several times at a later date, but without success. Probably the atmosphere was very dry when the discharges were seen, as similar phenomena have been observed when ebonite combs are used in frosty weather, the atmosphere being very dry. Those who use vulcanite shutters with their dark slides should, however, note the fact.

#### EXPOSURE OF THE BACK OF THE PLATE.

HERR R. E. LIESEGANG points out, in the current number of the *Photographische Correspondenz*, that all the advantages of multiple-coated plates may be obtained by exposing an ordinary plate through the back, his arguments in support of the statement being that the light incident on the opaque bromide of silver is very much weakened in its passage through the film, so that the side turned away from the glass will be considerably less exposed than the others. A plate thus exposed will behave in exactly the reverse manner to one exposed in the ordinary way; the developer acts, in the case of the plate exposed, from the back, first on the under-exposed layer of bromide particles, and the further it penetrates the more it comes into contact with the better-exposed particles. It is possible therefore to stop development when the desired density is obtained.

The advantage of exposing through the back is obvious when one considers the mechanics of the ordinary process, in which the developer acts most strongly on that portion of the film which has received the greatest exposure; with under-exposed plates this is not of much moment, but with over-exposure the plates exposed through the back have considerably the advantage. The effect of exposure through the back is stronger the thicker the coating of the plate. The amount of silver in the plate is used up better in this way, as in the ordinary method fogging of the plate frequently makes it impossible to develop far enough.

Orthochromatic plates show the good effect of this method of working, and the optical effect of the sensitiser is increased. Exposure through the back will be of special moment for half-tone work, as here the avoidance of fog is important. Process plates too are, as a rule, coated thicker than ordinary.

For ordinary camera work the reversion of right and left will always be a disadvantage, which, however, will not be felt in the case of films which are generally coated more thinly than plates.

#### FURTHER EXPERIENCES WITH LIPPMANN'S PROCESS.

DR. R. NEUBAUSS gives in the current number of the *Photographische Rundschau* some further notes on his experiments with Lippmann's process, which are not without practical interest.

He confirms his previous statement that Lautenschläger's gelatine is the only one that will give satisfactory results. The weather has considerable influence on the emulsion, and on hot, dry days, with an east wind, a successful emulsion cannot be prepared, and it is far better to make the same only on cool, rainy days.

The temperature of the emulsion at the time of mixing should not be higher than 31° C. in summer, nor more than 35° C. in winter, and the plates must be coated as quickly as possible, as the emulsion must not be heated up again. Although emulsions thus prepared are much slower, yet the colours are in every case more brilliant. It has been found advisable to heat the glass before coating to about the same temperature as the emulsion.

In many cases bleaching the results with mercury and blackening with amidol gives splendid colours; and, with compound colours, the best results were obtained by first intensifying with mercury and amidol, and then reducing with Farmer's reducer. It is better, however, if possible, to obtain results by development alone. The reducer must be used in extremely weak solutions, and ammonium persulphate cannot be used.

For albumen plates cleared albumen should always be used, and it is

better to use albumen solution that is at least from five to six months old. The albumen solution will keep for at least twelve months. Whilst the freshly coated albumen plates have a great tendency to frill in the alkaline developer, this fault is entirely avoided by using plates which have been coated for several months.

Professor Lippmann has pointed out that albumen plates may be developed with a plain, hot solution of pyrogallol, and this is of importance, as it is the alkali which tends to frilling.

Albumen plates which had been sensitised and dyed were found to give excellent results after ten months' keeping, so that it would be possible to place such plates on the market.

Dried albumen cannot be used, nor can the vegetable albumen introduced by Jolles & Lillienfeld.

#### ABOLISHING THE DARK ROOM,

[Paper read before the London and Provincial Photographic Association, January 12, 1899.]

THE modern dark room may be correctly described as follows:—A room in which the illuminant is seldom more than a single paraffin burner, the light from which, in four cases out of five, is reduced by being enclosed in a lantern, three of whose sides are opaque and from the remaining side the light endeavours to avoid complete extinction in escaping through deeply coloured media. The depths of darkness which are finally reached when the light (or what is left of it) has emerged from the glasses or fabrics employed for the dark-room lantern is best shown in the form of photometric measurements:—

Material.	Approximate loss of luminosity in the direct rays of the lamp.
Double-flashed orange (two thicknesses) ...	97.5 per cent.
Ruby (one thickness) and double-flashed orange (one thickness) .....	98.0 "
Deep ruby (one thickness) .....	99.0 "
Red (cherry) fabric (one thickness) .....	98.6 "

Therefore only two per cent. of the light, in the case of moderately safe media, is available for working.

In a communication to the Royal Photographic Society in May last, entitled, "A New Function of Developers," I gave an account of experiments undertaken with a view to ascertain how far this absence of light in the developing room can be avoided. In this communication the functions of the dark room were divided into two sections as follows:—

1. The protection of the film from actinic light during development.
2. The protection of the film during transfer to or from the developer, dark slide, &c.

In the subject-matter following, it was shown that the function under the first heading can be equally well fulfilled by the addition of certain colouring matters to the developer, and with this result, that, from the time the sensitive film is immersed in the coloured solution, the process of development and subsequent operations can be carried on in the ordinary white light.

The present paper gives the practical results of a continuation of the experiments, more especially as regards the functions of the dark room, which fall under the second heading.

Attempts were made to determine whether the illumination can be increased without sacrificing safety by making comparative trials with every likely colouring material, more especially with soluble aniline dyes, coloured salts, extracts, &c.

The rays from a small electric arc lamp were projected through dilute solutions of the colouring matters, and then through a spectroscope, and the portion of the spectrum where the maximum absorption occurred ascertained in each case.

Colouring matters or combinations of the same which gave complete absorption of all rays except red, orange, and yellow, were tested by exposing plates to the spectrum of the light which had passed through them, and by successive strengthenings of the solution, or one of them, according to which portion of the spectrum prolonged exposure gave a deposit, filters were obtained giving the maximum safety and transparency. The results obtained were remarkable.

Experiment I.—The light from a lantern, the illuminant in which is a sixteen-candle power incandescent film, was passed through a filter prepared in the manner described, the illumination being thereby reduced approximately fifty per cent., the candle power of the light emerging from the lantern being at least equal to that from eight naked candles, that is to say, the intensity of the light was fifty times greater than that from an ordinary lantern, and yet in this brilliant light instantaneous plates were as safe as in the latter case, an exposure of six minutes in the case of a Castle plate, at a distance of thirty inches from the lantern, having no appreciable effect on the film.

Experiment II.—The rays from an oil enlarging lantern were allowed at their point of crossing to pass through a similarly prepared filter. At a distance of twelve inches, where the diverging rays form a brilliant patch of light four inches in diameter, sensitive plates were developed with com-

plete immunity from fog—a half-covered Castle plate immersed in a colourless and energetic (rodinal) developer remaining twelve minutes without perceptible darkening.

These and many similar results give the following approximate figures:

	Approximate candle power of illumination for safety at two feet from lamp.	Relative illumination for equal safety.
Double flashed orange glass .....	·08	1
Liquid filter .....	6·0	80

These figures are better realised when we remember that the luminosity of a bright sky is only thirty times greater than a surface of black matt paper.

The explanation of this difference between the supposed necessarily limited illumination of the film and the unsuspected comparative

Section of Developing Room with Illumination Equal to Naked Gas Flame (10 candles).  
A, light; C, filter; B, mirror; D, eye.

brilliance of illumination which experiment shows can with safety be employed is very simple, and is due to two causes.

I. The low absorption equivalents (*i.e.*, transparency) of the colour filters in use for many of the rays to which films are highly sensitive.

II. To their high absorption equivalents (*i.e.*, opacity) for many of the rays to which films are least sensitive.

The custom has become general of working immediately in front or at one side of the light; in other words, "work is carried on in the position of maximum illumination." The advantage and even necessity of this

mode of working is obviously due to the low luminosity of the light emitted from the lanterns; but, when by the use of colour filters which have been adjusted to give the maximum safety and transparency the illumination is increased from ten to a hundred fold, an entirely new system of lighting becomes feasible—a system in which the bench and sink become the position of minimum illumination—in which the general lighting (although the more actinic rays are completely absent) is made equal to that from naked oil, gas, or electric lamps, and we have a room which in no sense of the word can be termed *dark*, and in which the handling of sensitive plates and the operations of development can be carried on under conditions vastly more efficient and comfortable.

It is obvious that, notwithstanding the blue and violet rays are entirely eliminated, an illumination of ten or twelve candle power in red and yellow rays would be fatal to orthochromatic plates; and where such are employed I complete the system by enclosing with wood or curtains a small space on the bench to form a shelter in which the plates are transferred to dark slide and developer, and, when once in the latter, all need of protection ceases, by utilising the very practical method described in my paper to the Royal Photographic Society previously mentioned.

My remarks hitherto have referred to what may be termed permanent developing rooms. To those who only require conveniences for occasional development, and have no room from which white light can be excluded, I recommend the use of a shelter such as has been referred to in conjunction with my safety developers.

In case there may be any here or among those who are groping in darkness in more distant places who doubt the practical nature of the remedies offered, or who still think that a developing room is necessarily also a dark room, I shall be very glad to show our system at the Polytechnic.

E. HOWARD FARMER.

#### AN ILLUSION AND ITS CAUSE.

On the top of a hill that forms my western horizon line stands a number of buildings. One evening recently I watched the sun setting beyond the buildings, and saw something which, says Mr. R. M. McCreary in *Popular Astronomy*, if I had not often witnessed similar appearances, I would have regarded it as a wonderful phenomenon. The sun looked larger than the buildings; it passed directly behind one which I know is fifty feet long, and I saw the whole building projected on its disc, and there was disc room for more, so that the sun on that occasion appeared to be more than fifty feet in diameter.

Why was this? What caused the illusion? For it was an illusion, as a little experiment described in Sec. 88 of Young's *General Astronomy* will demonstrate. Or, to make the question general, why does the sun, and the moon, too, appear larger when near the horizon than when at a high altitude? The question is suggested whenever one sees the sun or the moon rise or set; it has often been asked, but there is recent and, I suppose, good authority for saying that it has never been satisfactorily answered. Where many have failed it may be presumption for me to attempt, but I will attempt. If I succeed, a long-felt want will be supplied; if I fail, I shall get myself into good company—into the company of some who have been eminent for astronomical attainments, but who have tried and failed to account for the illusion.

I will begin by supposing a case. Suppose a lady goes shopping and buys a piece of goods; she returns home and measures her purchase with what was once a yard stick, but from which, unknown to her, a piece has been cut. She will think that she has more goods than she purchased. Suppose, further, that the lady cannot see or cannot be convinced that her supposed yard stick is not a yard long. In that case she will go down to her grave firm in the opinion that she had got the big end of at least one bargain. Now, something analogous to this happens whenever we see the sun or moon apparently enlarged. When we see those bodies high in the sky, we apply to them angular measurement, and thus see them as of their true angular diameters. We are then in the same state of mind as was the lady when she left the store with her purchase. But, when we see the sun or moon near the horizon, we apply to them linear measurement, the dimensions in feet, yards, or other units, which we know or can always very closely estimate, of houses, trees, fences, or other terrestrial objects near which they appear; but we do not take account of the shrinkage which, owing to distance, our measuring instruments have undergone. In consequence, the sun or moon, in the position supposed, appears to be enlarged just in the ratio that the distance-reduced size bears to the real size of our comparison objects. We are deceived just as the woman was deceived when she measured her stuff with a yard stick that was not a yard stick. And we will continue to be deceived. As the woman in the little fable I have constructed pins her faith to her supposed yard stick, and lives and will die under an hallucination, so we, as long as the sun and moon shall rise and set for us, will apply to their measurement our distance-diminished terrestrial standards, and, in consequence, we will continue to see those bodies apparently enlarged, according to the distance that intervenes between us and our standards of measurement.

It cannot, in the nature of things, be otherwise. We carry in our minds definite ideas of linear extension, of the length of a foot, a yard, a rod, and, within reasonable limits, of their multiples, and, when we know or estimate that a terrestrial object corresponds in extent with

any number of these units, we see it, and we cannot help seeing it, whether it is nearer or more remote, as of that size. We see it in its true or estimated linear dimensions, notwithstanding, or in spite of, the fact that we know that its angular size is reduced by distance. A man six feet high seen at a distance of a quarter of a mile really measures about an inch, but we see him as a man; a panel of a fence a mile away measures about three-quarters of an inch, but we see it as a rod; and the house, behind which I saw the sun setting, seen from my window, actually measures but little more than half an inch, but I see it as a fifty-foot building. I saw it so on the occasion noted; I used it for measuring the sun, and, as my standard of measurement appeared magnified nearly a hundred-fold, the sun seemed enlarged in exactly the same ratio.

I did not set out to explain why we see terrestrial objects in their true proportions regardless of distance. It is the result, I suppose, of experience. But the explanation is not necessary; the fact that we see objects so and employ them as thus seen, instead of as they ought to appear, for measuring the discs of the sun and moon is, I believe, the cause of the illusion which it was my purpose to explain.

The illusion for which the foregoing is an attempt to account must not be confounded with a similar illusion arising from a different cause, that is, the moderate, gradual change in the apparent sizes of the lunar and solar discs which they undergo as they recede from the eastern or approach the western horizon. The latter illusion is owing, as was long ago explained by Alhazen, to the apparent ellipticity of the sky, in consequence of which we see the sun and moon projected on a background that is nearer or more distant, according as those bodies are viewed at a higher or lower altitude. We view, not the sun or the moon directly, but its projection on the sky, and the illusion appears; if we view them directly, through smoked or coloured glass, the background cannot be seen and the illusion vanishes.

#### ALBUMS: MR. R. DALTON'S SYSTEM OF HOLDING SEPARATE PAGES OF LEAVES.

SEPARATE pages or leaves are held in a specially devised holding appliance in which they are, by being specially slotted, adapted to fit. The appliance, which is mainly designed to hold the pages or sheets of

postage-stamp collections, or sheets of photographs, or other like sheets or pages, is so devised that any page or pages held by it can be withdrawn from among others at will, without causing displacement of such others, and without necessitating special holding of such others otherwise than by the appliance.

The appliance consists of an open-ended shoe of brass, gun metal, or

other suitable metal or material, the sides of which project from the back or sole at approximately a right angle. Extending across from one side to the other bars are situated at suitable distances apart. One of these bars is free to be moved within the limits of slots provided in the sides of the shoe. This bar is, for convenience in description, termed the locking bar. On the fixed bars are loosely suspended the separate pages,

leaves, or sheets, which, for that purpose, are provided with slots having shoulders, which prevent movement in the direction of the length of the shoe. The pages, leaves, or sheets, are also slotted to accommodate the locking bar, but the slots therefor are not shouldered.

The pages can be withdrawn only when the locking bar is in the unlocked position, as, when the locking bar is in the locked position, it lies in the slot provided for it in the pages, and prevents withdrawal.

When, however, the locking bar is moved to the unlocked position, by drawing it out of the slots in the pages, the latter can be drawn outwards, so that the shoulders aforesaid are clear of the fixed bars. The pages can then be moved in the direction necessary to free them from the bars. As aforesaid, any page or pages can be removed from the holder without displacement of the remaining pages, which, although unlocked, remain suspended.

Under a modification, the slots made in the pages for the fixed bars are not shouldered, and the locking bar works into and out of a shouldered slot with a direction of movement of a right angle to that in which it works in the arrangement above described.

Fig. 1 is a view of one form of the appliance for holding separate pages, leaves, or sheets.

The appliance consists of a shoe, *a*, of brass, gun-metal, or other suitable metal or material, the sides of which project outwards from the back or sole at approximately a right angle. Extended across the shoe are fixed bars, *b*, and a movable bar, *c*. The bar, *c*, is capable of being moved within the slots, *d*, provided in each side of the shoe, *a*. For convenience in description, the bar, *c*, is termed herein the locking bar.

At fig. 2 is shown part of a page, leaf, or sheet, *e*, adapted to fit into the holder. Behind the hinge, *f*, which is a flexible band strengthened by linen or other suitable fabric, the page is slotted. The upper and lower slots are shaped so as to form shoulders, *g*. The middle slot, cut in the pages to take the locking bar, *c*, of the holder, is not so shouldered. At fig. 3 is shown a set of pages arranged bookwise in the holder, which is fixed to a backing, *h*, of wood or other suitable substance, to which are attached covers, *i*. In placing the pages in the holder, the locking bar, *c*, is first drawn down towards the bottom of the slot, *d*, and the pages, *e*, are then loosely hung on the bars, *b*. The locking bar, *c*, is then moved up in the slot, *d*, which it fits, and thus the pages, *e*, are locked on the holder. When the locking bar, *c*, is drawn down, any page or pages can be removed and replaced without necessitating removal of any

others, and without necessitating holding such others, otherwise than by the appliance.

At figs. 4, 5, and 6 of the drawings is illustrated a modification, according to which the locking bar, *c*<sup>1</sup>, works in a direction at right angles to that in which it works in the form of appliance shown at figs. 1, 2, and 3. The slots made in the pages for the fixed bars, *b*<sup>1</sup>, are not shouldered as in figs. 1, 2, and 3. The slot cut in the pages to take the locking bar, *c*<sup>1</sup>, is shaped as shown. As aforesaid, the bar, *c*<sup>1</sup>, works up and down in the slots, *d*<sup>1</sup>, in the holder towards and away from the face of the book. When the bar, *c*<sup>1</sup>, is drawn up in the slot, *d*<sup>1</sup>, as seen at fig. 6, the pages are locked in place. When it is required to move a page or pages, the locking bar, *c*<sup>1</sup>, is first pressed down to a sufficient degree, and removal of the page or pages is effected by drawing the said page or pages towards the top of the book until the slots in the page or pages are clear of the bars in the holder.

#### McKELLEN LIMITED.

THE business of Messrs. S. D. McKellen & Co., photographic-apparatus manufacturers, of Manchester, has been converted into a limited liability company, with a capital of 6000*l.*, divided into 6000 shares of 1*l.* each, of which 4000 are Ordinary shares and 2000 Deferred shares. The Deferred shares do not rank for dividend until a cumulative preference dividend of six per cent. per annum has been paid upon the Ordinary shares, and after a similar dividend has been paid upon the Deferred shares all the shares rank equally in the distribution of further dividends. The whole of the Deferred shares and 1000 of the Ordinary shares are taken as fully paid by the vendors in part payment of the purchase money, and the balance of 3000 Ordinary shares are now offered for subscription, payable 5*s.* per share on application, 5*s.* on allotment, and the balance when called for.

The directors are: Alderman R. Lovett Reade, Sale New Hall, Sale, Cheshire (Chairman); and Messrs. Walter G. Bagnall, J.P., Aspinshaw Hall, Derbyshire; William Barratt, Crumpsall, Manchester (Manager of the Manchester and Salford Microscope Company, Limited); Joseph Clare, J.P., Greenfield, near Oldham; Samuel Cowan, Ellesmere Park, Eccles, near Manchester (Cowan & Sons, opticians, Manchester); Abraham Rhodes, Birstall, near Leeds (Oakwell Soap Company); Samuel D. McKellen, Crumpsall, Manchester (Managing Director).

Messrs. McKellen & Co.'s latest inventions are: (1) the "Cathedral" Hand and Stand Camera; (2) the Triple Action Roller-blind Shutter; (3) the Aluminium Safety Shutter; (4) a Cycle Carrier for the safe carrying of fragile articles.

Mr. S. D. McKellen's services have been secured to the Company for a term of five years.

It is estimated that, upon a very moderate turnover, profits can be earned with the capital of the Company sufficient to show a dividend of considerably over twenty-five per cent. per annum.

The offices of the Company are at 4, Bull's Head-yard, Manchester.

#### PHOTOGRAPHING A FUNERAL.

At the Scarborough Quarter Sessions, before the Recorder, Mr. Charles Haigh, and a jury, an interesting case came on for hearing, in which Edwin Stead, photographer of Aberdeen-walk, Scarborough, sued John Waters, of the Equestrian Hotel, St. Thomas-street, Scarborough, for payment of 10*l.*, being the amount due on a dishonoured cheque. The circumstances of the case were somewhat peculiar. The defendant is an hotel-keeper, and also an amateur photographer, and his hotel, which is in St. Thomas-street, faces into Elder-street, from which street the funeral took place of Mrs. Brooks, the wife of a hairdresser, and her six children, who were burned to death in the Queen-street fire in June last. Defendant conceived the idea of photographing the funeral procession from the window of his hotel, and, although there was a dispute as to who actually took the photograph, it was admitted that both plaintiff and defendant were at the operation. The defendant then asked plaintiff to develop the plates, and get proofs to show to his customers, on the following day.

Thinking that he might make a profit on the transaction, he consulted plaintiff, and eventually 5000 copies in collotype, were secured. These copies were offered for sale. The plaintiff contended that by securing these for the defendant at the trade price he saved the defendant 7*l.* 10*s.*, and, in view of that and his other trouble, he claimed 10*l.* This, the defendant pleaded was excessive, but, on October 8, he gave a cheque for that amount to plaintiff, who, on going to cash it next day, was told that payment had been stopped by the defendant. The story of how the cheque was granted, as told by the plaintiff, was that the defendant went to his house late on a Sunday night, and said he had come to pay his account. Plaintiff had hitherto considered that the affair had been carried through as a sort of partnership, and told defendant that he thought he was entitled to half the profit realised on the photographs. The defendant said he could not agree to that, and that he intended to pay plaintiff merely his charges for his trouble. Plaintiff then said his charge would be 10*l.* Defendant demurred, and said he did not think it would be so

much, but he eventually took plaintiff back to his hotel with him, and made out a cheque for 10*l.* He remained there an hour, at the end of which time defendant asked him to let him look at the cheque again to see if it was all right. He did so, but, as he thought defendant was looking at it a long time, he got a little annoyed, and saying, "Is it not all right?" got hold of it, and in doing so tore it. On the following day he took it to the bank and found that defendant had stopped it.

The defendant stated that, while plaintiff asked 10*l.*, he told him that he was prepared to pay his account when he received a detailed statement, but the plaintiff asked him to give him a cheque for 10*l.*, merely to show his wife, and that he would give him a detailed statement of account, and that they would settle upon the morning. He agreed to do so, on condition that plaintiff agreed to tear the cheque across in his presence, and that the plaintiff did. In the morning, as plaintiff did not appear with the detailed statement as promised, he went to the bank, and stopped payment of the cheque. He paid 8*l.* into court and contended that this was sufficient for any service rendered by the plaintiff. The defendant said he took the photographs himself, but the plaintiff declared that the defendant had focussed the machine too high, and would only have obtained views of the County Court buildings and the bright blue sky. The jury eventually returned a verdict for the plaintiff for the full amount claimed, and judgment was given accordingly with costs.

## Our Editorial Table.

#### THE IMPERIAL SPECIAL SLOW BROMIDE PAPER FOR GASLIGHT DEVELOPMENT.

Manufactured by the Imperial Dry Plate Company, Orickwood, N.W.

IN sending us for trial samples of their newly introduced special slow bromide paper for gaslight development, the Imperial Dry Plate Company remark that in their researches, which have extended back for a considerable time, they have kept in mind what they consider to be the useful and practicable features. They rightly point out that a paper, to be sufficiently slow to be conveniently manipulated in ordinary gaslight, must be correspondingly slow in exposure. They have endeavoured to produce a paper of just the right sensitiveness, requiring an exposure not so long as to be inconvenient, the average exposure being twenty seconds, and yet not so sensitive as to become veiled from light exposure when working at a convenient distance from an ordinary gas flame. They have kept in mind also the necessity for pure blacks, for perfectly clear high lights, and for the range of tone to be all that could be desired for the most delicate portraiture. They manufacture the paper in two grades, rough and smooth; they have also resumed the manufacture of the ordinary rapid bromide paper suitable for enlargements.

The principal directions for use are as follows: The packets may be opened in ordinary gaslight a few feet from the flame. The exposure required for contact printing from a negative of average density is about twenty seconds at a distance of three inches from an ordinary gas burner. Avoid over-exposure, which will affect the purity of the whites and tend to give greenish blacks. For enlarging, the correct exposure should be determined by making a trial exposure on a small piece of paper. Any of the usual developers for bromide paper may be used. Use a perfectly clean developing dish, and flood the paper with water for a few seconds, then drain off. Pour the developer on so as to carry it in an even wave over the entire surface of the paper. Beware of air bells, which adhere to the film and cause white circular spots. During development the worker should remain at a distance of a few feet from the source of illumination, and, during the earlier stages of development at least, stand between the light and the developing dish. When development is nearing completion he should turn towards the light, in order more easily to judge when development is complete. If it is inconvenient to get to a distance of a few feet from the light, the flame should be somewhat lowered. For normal exposure the development should be complete in one minute, when the print should be rinsed in water and transferred to the fixing bath.

Following the instructions here given and using a metol-hydroquinone developer, we produced results of the most excellent qualitative character. The paper strikes us as easily capable of yielding a rich black, well-graduated image, with clear whites such as cannot fail to please the most critical taste. We welcome the introduction of this paper. Only last week, as our readers are aware, we were urging manufacturers to take up the preparation of slow-emulsion papers for development in actinic light, and we are glad to note that the Imperial Company amongst native houses are early in the field. The paper is quicker than others we have tried, a feature which, *pari passu*, is distinctly in its favour.

#### AMATEURS' PHOTOGRAPHIC REQUISITES.

The London Stereoscopic Company, 106 and 108, Regent-street, W., and 54, Chancery-lane, E.C. 176 pp., price 8*d.*

IN this elegantly produced catalogue the London Stereoscopic Company gives illustrated particulars of a large variety of photographic apparatus specially chosen with a view to meeting the requirements of amateurs. The many departments of photographic production which the Company

undertake are also set forth, so that it would not be easy to name a respect in which the London Stereoscopic Company can fail to be of service to its numerous clientele. A feature of the book is that it was actually printed at the Company's own works at Southgate. Viewed as an example of typographical production, it extorts very high praise.

#### CAMERA NOTES: THE OFFICIAL ORGAN OF THE NEW YORK CAMERA CLUB.

Published by the N.Y. Camera Club, 37 West Twenty-ninth-street, New York.

We have before now had occasion to refer to *Camera Notes* as a production in which the possession of a highly cultivated artistic taste is manifested by those upon whom the superintendence of its publication devolves. The receipt of the January number gives us the opportunity of noting that the high standard of excellence initially set up has been steadily kept in view. *Camera Notes* may without hesitation be termed the best publication of its kind—no other Society in the world sends out such a delightful and informative organ. Bound in a tasteful stiff green cover, printing, paper, and illustrations are all of the best. The present number contains four whole-page photogravures and several half-tone reproductions, both kinds of pictures being wonderfully good. The articles exhibit a preponderance of attention to critical writing, but there are many useful practical hints to be derived from a study of the pages of *Camera Notes*. Photographs by Miss Johnston, Mr. Hollinger, Mr. W. A. Fraser, Mr. Stieglitz, and Mr. C. J. Berg are reproduced. We advise all who would like to see one of the most artistic photographic publications that have come before us to obtain a sight of *Camera Notes*.

#### PHOTO-MICROGRAPHY.

By EDMUND J. SPITTA, L.R.C.P. Lond., M.R.C.S., &c. London: The Scientific Press, 28, Southampton-street, Strand.

Those of our readers who, last winter, had the advantage of hearing Mr. Spitta lecture on photo-micrography before the Royal Photographic Society and elsewhere, will easily recall the fact that the author handled his subject with the practised skill of a past master of this highly refined branch of work. We were glad to observe that for some months past Mr. Spitta has been extending his theme in the pages of our esteemed contemporary, the *Pharmaceutical Journal*. The time was ripe for a good book on photo-micrography, and Mr. Spitta's admirable articles form the basis of the present very painstaking and conscientiously prepared volume. He eschews theory and the more abstruse aspects of his theme, which he treats throughout in such a plain and practical style that there is not the smallest difficulty in following him into all its minutiae. Indeed, it is characteristic of Mr. Spitta that he dots his "i's" and crosses his "t's" so unsparringly that even an intelligent reader knowing nothing of photo-micrography, would, we are sure, be able quite easily to follow the author's teaching and meaning. Mr. Spitta separates his subject into three parts: low power, medium power, and high power work. The photographic instructions are copious and clear, and, when we come to the purely microscopic side, the author's definitions are commendably lucid and his working directions easily comprehensible. The very latest forms of microscopes are illustrated and described with the utmost fulness, and the student or beginner is not left in doubt as to the best and most suitable apparatus to select for particular kinds of work. In all there are sixty-three illustrations of this kind, and forty phototypic reproductions from negatives by the author and his son, Mr. Harold Spitta, inserted as examples of photo-micrographs produced in the three degrees of magnification above mentioned. Numerous appendices of a very informative kind and a full index complete a work of the highest value to the beginner as well as to the advanced student. The half-tone illustrations do great credit to Messrs. Dent, and the book as a whole is a most useful and instructive one.

#### CATALOGUE RECEIVED.

The Thornton-Pickard Manufacturing Company, Limited, Altrincham, Cheshire.

A GLANCE through the Thornton-Pickard Company's 1899 Catalogue reveals the fact that the famous Altrincham house is quite abreast of the times in meeting the demand, which never ceases in photography, for something new in apparatus or material. Thus the catalogue apprises us that a new time-exposure valve has been devised for use with the well-known Thornton-Pickard shutters. This valve allows of time exposures from one-eighth of a second to three seconds being obtained automatically, a manifest convenience not heretofore available in respect of the minimum exposure. Amongst other novelties to which reference is made in the catalogue are the new Ruby convertible lens, a non-symmetrical doublet allowing of three foci being obtained, a new cycle-luggage carrier, new Ruby cameras, &c. There are a number of excellent illustrations of photographs that secured prizes in the Company's recent competition. The catalogue is sent post-free to applicants.

MESSRS. J. J. GRIFFIN & SONS, Limited, of 20-26, Sardinia-street, Lincoln's Inn-fields, W.C., has sent us a sample of their own brand of ammonium persulphate, the most recently introduced negative reducer. This in every way answers the purpose admirably.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, January 25, at eight o'clock Travellers' Night. "The Hand Camera at Home and Abroad," by Mr. R. Child Bayley.

ROYAL PHOTOGRAPHIC SOCIETY.—Technical Meeting, Tuesday, January 24, at 12, Hanover-square, at eight p.m. "The Development of Gelatino-chloride Papers," by John Sterry.

THE AUSTIN-EDWARDS MONTHLY FILM-NEGATIVE COMPETITION.—The prize camera for the current month has been awarded to Mr. W. Wright, 29, St. John's-road, Watford, Herts, for his negative, *Wood in Autumn*.

THE following are the names of the prize-winners in the Warwick Monthly Competition for January:—1st prize, 20s., Mr. F. W. Levett, 116, Loughborough-park, London, S.W.; 2nd prize, 10s., Mr. G. Stone, 25, Faringdon-street, Swindon; 3rd prize, 5s., Mr. E. G. Boon, Malino di Sopra, Allassio, Italy.

MESSRS. ARCHER & SONS, of 43-49, Lord-street, Liverpool, inform us that they have taken over the business of Messrs. Wood Brothers, including "Wormald's Specialities," 73, Lord-street, Liverpool, and will continue the business under the same names and address for the present. Wormald's Specialities will in future bear Wormald's name only.

ONE of the attractions of the Paris Exhibition is to be the Mareorama, devised and painted by M. Hugo d'Alési, the well-known poster artist. After duly paying his fee, the visitor will pass a gangway, and find himself on the deck of a first-class passenger steamer, with captain, crew, rigging, smoking funnels, and every other detail complete. Around stretches a blue and sparkling sea, whilst behind may be seen the port of Marseilles fading away on the horizon. Machinery imparts a pleasant rocking motion to the fictitious vessel, and a concealed fan makes a breeze as the traveller skims past Le Frioul and the Château d'If. The sun sets and rises to reveal Naples and Vesuvius, and, having safely passed between Scylla and Charybdis, the good ship reaches in a few minutes the harbour of Sfax in Tunis. Venice will be the next halting place, and finally the passengers glide up the Bosphorus to Constantinople, but a storm must first be faced. The illusion throughout is said to be marvellous.

A SOME memorable in the annals of the weaving industry was, says the correspondent of the *Daily Chronicle*, witnessed on January 10 at the Vienna Technical Art Museum. Herr Jan Szczepanik, the famous young inventor, presented the Emperor Francis Joseph with the first web produced by means of his new photographic process, which was described last May. The silk-woven gobalins is made from a picture by Henryk Rauchinger. It is about two square metres in size, and gives an allegorical representation of homage to the Emperor. The work contains 200,000,000 crossings, 120 silk threads filling one centimetre. Two hundred square metres of pasteboard cards would have been necessary to produce this web according to the present method, and designers would have required many years to carry out the work. Now the designer is abolished, and the work was done in five hours. The Emperor was struck by the marvellous plasticity and delicacy of the picture, which nobody would believe to be woven. Herr Szczepanik demonstrated the process at the Emperor's desire, and His Majesty accepted the gift, and congratulated the inventor.

INTERNATIONAL PHOTOGRAPHIC EXHIBITION.—In connexion with the National Trades and Industrial Exhibition, to be held at Bingley Hall, Birmingham, from March 20 to May 13, there will be a photographic section of considerable importance. Mr. George Stanley, the Manager of the Trades Exhibition Company of London, has arranged with Mr. Walter D. Welford, who is well known in connexion with photographic exhibitions, to take entire charge of the photographic portion. Gold, silver gilt, silver, and bronze medals, and special prizes will be offered for various competitions, and the latter will be arranged to suit all classes, professional, amateur, and novice alike. Mr. Welford at previous exhibitions has always endeavoured to provide something out of the common run in the way of medals, and at Birmingham there will be a specially handsome design, and not of the usual round pattern. Prospectuses will be ready shortly, and may be obtained from his office at 19, Southampton-buildings, Chancery-lane, London, W.C., or from the Trades Exhibition Company, 80, Coleman-street, London, E.C.; and, as the time fixed will be during a quiet time as regards other exhibitions, it will afford a good opportunity for our workers.

## Patent News.

THE following applications for Patents were made between January 2 and January 7, 1899:—

STEREOSCOPIC LANTERN PROJECTION.—No. 27. "Stereoscopic Views for Lantern Projection." J. H. KNIGHT.

"SNAP-SHOT" APPARATUS.—No. 201. "New or Improved Photographic Apparatus of the class known as 'Snap-shot.'" Complete specification. PASCAL & IZERABLE.

"TREATMENT OF PHOTOGRAPHICALLY PREPARED SURFACES."—No. 243. "A New or Improved Apparatus for the Mechanical Treatment of Photo-graphically Prepared Surfaces during the Developing and Finishing Processes." W. F. CRAWFORD.

STEREOSCOPES.—No. 265. "Improvements in Stereoscopes." Communicated by Knackstedt & Nather, Germany. H. H. LAKE.

- EXTINGUISHING KINEMATOGRAPH FIRES.**—No. 317. "A New or Improved Means for Extinguishing Accidental Fires in Kinematographs and the like Instruments." B. VAN DER WERFF.
- APPARATUS.**—No. 332. "An Improved Photographic Apparatus." Complete specification. L. NEUMAYER.
- ARC LAMP.**—No. 338. "Improved Electric Arc Lamp for Portrait Photography." G. W. MORGAN.
- KINEMATOGRAHS.**—No. 389. "Improvements in Apparatus for use in connexion with Kinematographs and similar Instruments." C. W. HOLLIS.
- CAMERAS.**—No. 409. "Improvements in Photographic Cameras." H. H. SHANKS and P. B. W. KERSHAW.
- TRAY.**—No. 412. "Improved Photographic Tray." J. HENDERSON.
- ANIMATED PHOTOGRAPHY.**—No. 418. "An Improved Method of Producing Photographic Pictures for Use in the Representation of Animated or Moving Objects." C. RALEIGH.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

January.	Name of Society.	Subject.
23.....	Bradford Photo. Society .....	<i>The Joys and Sorrows of Photography.</i> P. E. Newstead.

### ROYAL PHOTOGRAPHIC SOCIETY.

JANUARY 17,—Photo-mechanical Meeting,—Mr. H. Snowden Ward in the chair.

#### HALF-TONE SCREENS.

Colonel J. WATERHOUSE, I.S.C. (Hon. Secretary), read a paper by Mr. J. E. Johnson, on "Some New Half-tone Screens of English Manufacture," in which the author first pointed out the increase in detail obtained by the use of screens of 100, 200, or 400 lines to the inch, and that, with screens of the latter ruling, and with suitable precautions, negatives with a cross-lined ruling might be secured possessing no more actual grain than the wet or dry plate itself, and that consequently the mechanical cross-line effect of the ruling was lost. Still, there were such difficulties in the way of making half-tone blocks with screens of 400 lines to the inch that no process-worker had sufficient confidence in himself to undertake the work. The great drawback lay in the fact that the finest half-tone printing inks contained hard substances, due chiefly to imperfect grinding, which were much larger than the grains of silver deposited in the negative, and consequently not more than twenty-five clear impressions could be obtained without washing the block. A further difficulty arose from the presence of irregularities in the surface of the paper, preventing perfect contact. If manufacturers of paper and ink were to give their attention to these matters, they would soon find a ready market for their goods, but the author of the paper fully recognised the great advances in this respect which have been made in this country in recent years. Although very good results were obtained, even with a cross-line screen of 150 lines to the inch or less, the screen must be perfect to ensure success. The practical difficulties met with in the use of very finely ruled screens were referred to, and the absolute necessity for accurate ruling was insisted upon. Mr. Johnson said he had been occupied for fourteen years in perfecting a method of screen-ruling, by which he claimed to be able to etch

screens with 10,000 lines to the inch, as easily as with 40 lines to the inch, but he declined to reply to questions dealing directly with the means he adopted for the attainment of this end.

The reading of the paper was followed by a conversation in which many members and visitors took part, and which covered a wide field.

Mr. L. WARNERKE asked whether Mr. Johnson coated his glass with a resist and afterwards ruled with a diamond?

Mr. JOHNSON said he coated the glass with a varnish, and ruled with a diamond of the hardest quality. To make screens a man must be his own diamond-cutter, and he must have a thorough knowledge of process work in order that the cutting edge of the diamond might be made to properly answer the purpose for which it was intended.

Mr. SANGER SHEPHERD said the difference in the quality of screens was a question of skill in manipulation, and a perfect screw was of the greatest importance. There was no particular difficulty in getting a ruling machine to work satisfactorily up to 150 lines to the inch, but, beyond that, it was very difficult to get a screw which would allow a plate to be ruled in such a way as to pass a proper test. He had made many screens himself, using as a resist a compound of bitumen, wax, and bezole. The diamond he employed was about one-eighth of an inch long and something less than one one-hundredth of an inch wide.

Mr. DAWSON, comparing the effects obtained by the use of coarse and fine screens, said it was impossible to etch a block to a greater depth than the distance between the lines and the screen. He could not understand why a diamond was used to cut the lines in the resist, and not to cut them on the glass. Why was it necessary to etch at all?

Mr. SANGER SHEPHERD pointed out that one of the greatest difficulties in screen-ruling was to get the diamond to keep its edge, and that, if sufficient pressure were used to cut the glass, it would be hopeless to attempt to rule a screen of only two or three inches. As a matter of fact, when a screen had been ruled, and the resist removed, there was hardly a trace upon the glass to indicate the passage of the diamond, and any attempt to cut into the glass would result in utter failure so far as the screen was concerned.

Mr. JOHNSON said the diamond must not cut, and if it made the slightest possible grey mark, only perceptible under a microscope, the screen would be useless.

Mr. SANGER SHEPHERD detailed the method adopted by Mr. Ives, in the very early days, for the manufacture of screens. He coated plate glass with collodion, exposed to light, developed, intensified, and then ruled through the intensified film in a Richards' ruling machine. Being unable to obtain suitable diamonds, he made a cutter from a piece of watch-spring, hardened by plunging it into frozen mercury.

Mr. WARNERKE said he had adopted a somewhat similar plan, but using a silvered glass, the silver being cut away with a tool made in almost the same way as that described by Mr. Shepherd.

The Rev. F. C. LAMBERT, referring to the question of the respective widths of the black lines and the transparent interspaces, and the size of the dot, in which direction the conversation next turned, expressed his surprise that block-makers apparently used about the same screens, whatever the size of the picture might be. In his opinion, there should be no hard-and-fast rule as to the best size of the dot, which should vary *pari passu* with the size of the picture.

Mr. SANGER SHEPHERD had recently seen some American poster work, about 60 x 40 inches, made with a screen of twenty-five lines to the inch, and, when viewed from the distance at which a poster would ordinarily be viewed, the effect was very good indeed.

The conversation was continued for some time in an unconventional manner, and concluded with an expression of thanks to Mr. Johnson for his paper.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 12,—Mr. A. Haddon in the chair.

Mr. W. D. WELFORD read a letter he had received from Messrs. Burroughs, Wellcome, & Co., regarding sodium-formate toning. As a result of their experiments, they find that the following formula gives the best results:—

Sodium formate .....	7·5 grains.
Sodium bicarbonate .....	1 grain.
Water .....	5 ounces.
Gold chloride .....	0·5 grain.

The new formula differs from the old in the addition of the sodium bicarbonate. This salt serves to neutralise the acid formed during toning, and makes the action of the bath more even and more prolonged. The different chemicals required above are compressed in tabloid form of accurate weight, and, if these are used, one has only to take a tabloid of the formate and bicarbonate (combined), dissolve in 5 ounces of water, and add a tabloid of the gold chloride. Should toning be desired to proceed more slowly, the addition of more water, up to 10 ounces in all, will effect this purpose.

The CHAIRMAN pointed out that Mr. Henderson mentioned that it was advantageous to add carbonate of soda in the case of gold-formate toning, and of formic acid in the case of platinum toning.

Mr. HOWARD FARMER read a paper entitled

#### ABOLISHING THE DARK ROOM. [See page 39.]

At the conclusion of his paper, Mr. Farmer practically demonstrated his propositions. The room was lit by perhaps a dozen ordinary gas jets, none of which was lowered or obscured. At his side he had what he called a shelter, for the purpose of transferring his plates to the dish, an operation which, of course, could not be done in the light of the room. It was a box with a safe-light obtained from a candle placed outside a small window of coloured glass. Seeing that he could not illuminate the meeting room with the light referred to in his paper, for the purpose of the demonstration, he added to his developer a quantity of the dye solution itself, which would, in the ordinary method of development, enclose the source of light. The plate was accordingly placed in the dish in the shelter, the developer, coloured with the

solution of dye, poured on, and the dish then brought out into the light of the room. The plate was perfectly visible, and in a little time the image began to appear. Obviously, when the dish was rocked, the plate would be laid bare, so another dish was placed over the first for the purpose of agitating the solution, but in a room lighted only by the illumination referred to in the paper, when the developer would require no dye in it, this precaution would not be necessary. However, to show the experiment at all, the developer had to be stained in the manner described to take the place of the lamp and liquid colour filter. In due course the plate (Castle ordinary) was developed and fixed. The slight stain was removable in water, or could be instantly discharged by hydrochloric acid. Mr. Farmer passed round a photograph of the spectrum, taken through his colour mixture, showing that its action was to completely cut out all beyond the orange. At present he could not divulge the nature of the colour-filter solution. He was endeavouring to make solid screens of a permanent nature, but, while the liquid screens would last probably seven years in constant use, he had not succeeded in making a glass filter which would not in a little time be seriously affected by light, moisture, &c., and be ruined. The developer used in this instance was rodinal, one in nineteen.

Mr. J. J. SMITH asked whether the dye might be used with other developers than rodinal, or did any chemical action between the dye and the developing agents render this impossible by discharging the colour?

Mr. FARMER hastened to point out that he was not advocating the use of the dye in the developer, but as a filter for the lamp illuminating the room where operations were conducted. The method he had adopted in the experiment was merely to show how much light could be used with impunity. At the same time there was no reason why it should not be used in the way demonstrated with any other developer if so wished, and the cost of the dye stuff would not be prohibitive.

Mr. WELFORD was glad the lecturer was in agreement with himself. He had long advocated a greater amount of light in development than used by the average photographer, but he was surprised at the amount of light which Mr. Farmer had shown could be used with complete immunity from fog, and the plate was as visible as without any dye at all.

Mr. Farmer sketched the form of his lamp on the blackboard. It was an inverted glass dome, enclosing one of smaller diameter, the annular space between the two, of about half an inch, being filled with the dye solution. The inner one required some forty-two pounds of lead shot to keep it down, and the lamp was placed in this.

The CHAIRMAN suggested two beakers as preferable to the cumbersome vessels described; they would stand the heat well, and could be supported by their lips. He thought that all those who valued their eyes would value the method of illumination described by Mr. Farmer, to whom he conveyed the hearty thanks of the meeting.

Mr. FARMER, replying, said that the system was quite complete for those who had no objection to liquid screens. He would be pleased to show the system in operation at the Polytechnic to any who might call between the hours of ten and four, or seven and eight in the evening.

#### PHOTOGRAPHIC CLUB.

JANUARY 11.—Mr. Donald F. Burrage in the chair.

Mr. JOHN NESBIT showed and described a number of examples of the photography of the past. There was a collodion positive of his father, taken in 1853; some negatives on Burgess's emulsion—the first gelatine emulsion that appeared, antedating Kennett; some specimens on Kennett's pellicle emulsion, being an attempt at stereoscopic-picture making with two separate exposures, no binocular camera being available; Stuart Wortley's emulsion; and Mawdsley's Liverpool collodion tannin dry plate, called, in those days, the Liverpool dry plate. Mr. Nesbit also passed round a negative made by Bolton's washed collodion emulsion process, a plate requiring some thirty times the exposure of the ordinary gelatine plate of the present time. All the examples shown were undoubtedly good average specimens of the work of the particular processes mentioned. One of the varnished negatives was affected by some trouble, the cause of which Mr. Nesbit was at a loss to explain. It displayed a milkiness from the edge towards the centre, and the general opinion was that damp was the cause. This damp might have been in the film at the time of varnishing, or the varnish itself might have been charged with moisture, or, again, the damp might have reached the plate at some subsequent period.

**Camera Club.**—There are few persons who will not agree that the best and most luxurious manner of taking a trip to the East *via* the Mediterranean is to do so in a well-appointed yacht, and, if you are so fortunate as to be the proud owner of such a vessel, so much the better, for then you will often have the satisfaction of declaring, as Robinson Crusoe did, that you are monarch of all you survey. The Rev. N. R. Fitzpatrick is such an experienced navigator that one feels an inclination in writing his name to reverse his initials and place them last of all. He owns the steam yacht *Evangeline*, of 230 tons burden, and he gave to the Camera Club on the 9th inst. a vivid account of a recent

#### CRUISE TO THE GOLDEN HORN

in that vessel. The story he had to tell was the story of a yachtsman, and he was able to illustrate his remarks in a very interesting manner by a large series of photographs taken by himself and members of his family who were fellow-voyagers. Among them they carried quite a battery of cameras, and opened fire, as "General" Booth would say, upon everything and anything that came in their way. Most of the plates, &c., were purchased in London before going on board, but it is interesting to learn that three dozen plates of a well-known home brand were procurable at Constantinople in first rate condition. First we were shown a picture of the *Evangeline*, and a very pretty craft she is; then we saw her crew of thirteen men, and her passengers numbering seven. The yacht was absent from England from April 20 to July 18, and it consumed during that time 200 tons of coal and eighty-four

gallons of oil. The fuel was rather expensive, for the Welsh coal strike was in progress at the time, and the lecturer warned his audience not to choose such a time of agitation in the coal trade to start on a yachting cruise. In his case the result was bad coal at 28s. per ton, with a strong suspicion that every ton did not contain twenty hundredweight. The ship had its saloon, state cabins, and drawing-room, and was well fitted up in every respect; it was lighted throughout by electricity, and its owner was prepared to kill or cure, for he carried among his stores a quantity of gunpowder and a liberal supply of castor oil. The vessel was equipped with a steam launch, a cutter, and a boat for sailing, and, as for the crew, "they looked nicer in the picture than when they came up for payment of wages every week," said the lecturer. The vessel covered 6000 miles during the trip, but the owner did not go the whole distance, for he had his Essex parishioners to think about, so he joined the yacht at Marseilles and left the crew to work it home at Brindisi. His absence from London, therefore, only amounted to six weeks. Before the *Evangeline* left Portsmouth Harbour, the owner went on board to see that all was right, the vessel being tried on the measured mile, and her compasses adjusted. Here she nearly came to grief one morning, H.M.S. *Seagull* all but running her down, and smashing a boat that was lying alongside. The lecturer was naturally put out at this *contretemps*, and not altogether satisfied with the apology sent by the admiral from the flagship, and he addressed a letter of remonstrance to the navigating officer of H.M.S. *Seagull*. There was much laughter when he explained that this letter was returned to him, and when he showed upon the screen a photograph of the envelope, endorsed, "Not known. There is no navigating officer on *Seagull*." Later on, as already explained, Mr. Fitzpatrick joined his yacht at Marseilles, and here it was that the first little difficulty occurred. The anchor could not be raised, upon which the harbour master suggested the aid of a diver, and, as this individual was found alongside and ready to dive, it was surmised that there was collusion between the two men. However, for 55 francs the diver went down, released the anchor, and the vessel was borne on its way to Nice. After Nice the yacht proceeded to the beautiful harbour of Spezzia. The lecturer here alluded to the lovely character of some of the Mediterranean islands, instancing Elba as a place which should not be missed. He and his daughter landed here, and walked four miles to a village full of interest and teeming with inhabitants. On their way back in the evening, the fireflies hung like berries of molten metal on all the bushes; never had he seen anything more beautiful in effect. Next the travellers visited Naples, and visited Pompeii and Vesuvius. An excellent photograph of the crater of Vesuvius, belching volumes of smoke and stones, evoked much applause. "There is nothing in the world like Vesuvius, and nothing like Pompeii," said the lecturer. The yacht next went to Sicily, and the lecturer spoke in enthusiastic terms of the beauty of Taormina. Every place visited was photographed with its inhabitants, for the lecturer did all he could in the way of pictorial study of human nature, and exceedingly interesting some of these pictures were. He apologised for a few which were "Salonesque" in character, on the score that the vagaries of King Sol were quite as remarkable in these regions as they are at home. At Taormina there is a remarkable ruined theatre, which Mr. Fitzpatrick was about to photograph when a man rushed out and with violent gesticulations declared that photography was utterly forbidden without a written permit from Palermo, several miles away; but the lecturer knew how to evade this denial, he had simply to show money, and had immediate permission to carry his camera any where he liked. Rounding the toe of the boot-shaped peninsula, the yacht called at Crotone and anchored there, a proceeding which was evidently considered suspicious by the Customs authorities, for their boat pulled round and round the vessel all night. In the morning various traders also came to have a look at the travellers, and, when some of them were told that the yacht was short of mutton, they went ashore and brought back with them a live sheep. The travellers then made their way to Corfu. Here many photographs were taken, the mixed nationalities of that island affording many interesting subjects for the hand camera. These snap-shots, illustrating the home life and different occupations of the inhabitants, were among the most successful of Mr. Fitzpatrick's pictures. The yacht now steamed in a southerly direction, calling at Patras and Corinth, and went at half speed through the Corinth Canal. This recently cut waterway has been blasted out of the solid rock, which forms precipitous walls on either side of the canal. The journey through it occupies twenty minutes, and the toll is about 2l. After a short visit to Athens the travellers left Grecian waters and made their way towards the Dardanelles. Here, by some inexplicable mistake, they lost their way, and nearly ran on the rocks, for half an hour no one on board having the remotest idea where they were. A passing boat gave them their course, and they arrived at the entrance of the Dardanelles at sunset. Then they had to cast anchor, for no vessel is allowed to pass through the Dardanelles during the dark hours. Eventually reaching Constantinople, they visited the mosque of St. Sophia, and saw the sarcophagus of Alexander the Great at the museum. Several interesting photographs were taken here, including some of the crowds of runners who tear through the streets whenever a fire occurs—a thing which takes place very frequently. These men hurry to the conflagration ostensibly to put it out, but in reality to plunder the premises. They are dangerous fellows to come across, for they have a cheerful habit of sticking a knife into any one who impedes their progress. Notwithstanding this and other eccentricities of the unspeakable Turk, the lecturer came away with a better impression of the people than he had taken with him. Such faults as they have are due to the system under which they live and to the traditions under which they are reared.

THERE was by no means a large audience on Thursday, the 12th instant, to hear Dr. C. S. Patterson's able discourse upon the wonders of sea fishing, illustrated photographically, for on that night the wind and the rain were struggling for supremacy, and no one turned out of doors without strong compulsion. But Dr. Patterson had no reason to complain of want of interest on the part of those who did visit the Club, for he had a most attentive audience to address. He began his remarks by expressing regret that the sea angler had not, as yet, attracted the attention of any Landseer to paint him on canvas; what had been done in delineating the successes and failures of the

sea angler was by photography, and the amateur photographer was the operator. A broken reed this amateur photographer often was. Did he hear groans of dissent? Only let his listeners see some of the pictures that he was about to put before them, and they would acknowledge that the remark, though unkind it seemed, was amply justified. Photography in a boat, bobbing up and down on a choppy sea, was not an easy pastime, and, as the best of sea angling necessitated the use of such a boat, it could not be expected that his pictures would be brilliant examples of photography. On a pier it was different, and he would commence by showing a number of pictures of sea angling as carried on at Deal pier. Sea fishing, as a means of earning a livelihood, was one of the very oldest of industries, but sea angling—i.e., fishing with rod and line, a pastime into the mysteries of which he would initiate them that evening—was a very modern thing indeed. Indeed, it dated from only a few years back, when a small number of fresh-water fishermen tried the experiment of catching flounders in shallow sea water with their ordinary tackle. They had such excellent sport that they carried their researches further; but, when they came to try in deep water, they met with but poor results. Shortly afterwards, in 1887, a book on Angling in Salt Water was written by one John Bickerdyke, in which volume may be found a full account of the best kind of rod, tackle, bait, or fly, to use in the endeavour to capture the finny denizens of the deep. The book did not meet with enthusiasm on the part of the critics, but was derided to a considerable extent. The *Saturday Review* a few years later, in a leading article on the subject, said that "the idea of angling in the sea is repulsive to the human mind." Indeed, the whole thing was generally ridiculed. But presently there came a change in public opinion. The number of sea anglers rapidly increased, and the evidence became overwhelming that sport, and splendid sport too, could be obtained by using rod and line from a boat at sea. Then came the foundation of the British Sea Anglers' Society, who made it their business to provide boats, bait, to secure cheap railway fares for their members, and special hotel tariffs. Five years ago the Society numbered ninety members, to-day it has 1000, and it has thirty different stations on our coasts, each with its accredited agent and boatmen. All classes are welcomed to join this Society, provided that they be sportsmen and have a horror of catching fish by trawl, sieve, or in any unsportsmanlike manner. The first attempts to catch sea-water fish with fresh-water apparatus were not successful, because the tackle was unsuitable. The rod must be shortened, the line much thinner, and the winch much bigger to accommodate the length of line—about 100 yards—commonly necessary. Bass and pollock gave splendid sport, not inferior, indeed, to salmon fishing, at far less expense; and, of course, one always had the chance of hooking a monster. Thus at Brighton, not long ago, a shark of between two and three cwt. was caught, and conger eels of great weight were often captured on rocky coasts. Deal is the Mecca of the sea angler, and the lecturer described the method practised there of getting bait and proceeding to sea. He himself was there in late December, fishing off the Bank buoy, which lies a mile and a quarter off the pier, in his shirt sleeves, a record performance for the time of year. He showed a photograph of his catch, consisting of whiting and some large cod. He has known some big takes of sea fish; thus, on one occasion, with three rods, the bag consisted of three congers of an aggregate weight of 56 pounds, seventeen cod weighing 130 pounds, and 200 pounds of whiting. Sometimes a conger so big was captured that it became necessary to either let him go or allow him to have all the boat to himself.

**Croydon Camera Club.**—Wednesday, the 11th inst., was devoted to the illustration of how various magnesium flashlight lamps could be utilised for the photography of groups and portraits. The PRESIDENT (Mr. Hector Maclean, F.R.P.S.), in the course of a few introductory remarks, reminded his hearers that the Club had, so long ago as 1892, demonstrated the availability of magnesium powder for taking fairly large assemblages, when Mr. Oakley photographed those assembled at the first annual dinner. Later, Mr. White employed an ingenious combination of electric current, gun-cotton, and magnesium, with which fairly promising results were obtained. Messrs. Smith and Noaks were also referred to as having used the magnesium flashlight with notable success, as also had the President himself in the photography of children's parties. A brief description of M. Boyer's installation and methods was next given, and prints illustrating all the points raised were shown and circulated. Councillor Noaks and Mr. J. Smith also passed round prints illustrating interesting technical points.

#### SNAP-SHOT LAMPS IN ACTION.

At the close of the President's remarks, which included a warning to novices against using certain mixtures of other chemicals with magnesium powder, e.g., powdered chlorate of potash, sulphur, &c., dangerous explosions being thereby liable to happen, Messrs. J. Noaks, John Smith, Rogers, Isaac, and Watson opened fire upon groups of members. Some of the negatives were straightway developed, with promising results. Later on some character portraits were attempted, a member posing to represent first fine weather, and secondly foul weather. Various other ideas were similarly portrayed. The flash lamps used were mainly of the ordinary character, ignited in pairs. The only exception was a simple, cheap, and apparently effective arrangement made by Mr. John Smith. Briefly, it consisted of two stands, each made by fitting three wooden blind rods on to a small piece of wood, two tripods being thus fashioned at a cost of about threepence. To each of the above stands an ordinary (large bore) clay pipe was attached, the bowl of which had a piece of lamp wick fastened round it. The wick was saturated with spirits of wine, magnesium powder was placed in the bowl, and the spirits of wine being first ignited, the magnesium is blown through the flame, and burns with great rapidity and light. Attached to the stem of each pipe was rubber piping, which joined on to a single length, at the end of which was a bulb, which produced the needful puff of air to blow the powder through the flame. Mr. Smith demonstrated that it was quite possible, though rather inconvenient, to do without the bulb, by simply using his mouth to blow down the rubber tubing.

**Hackney Photographic Society.**—January 10, Mr. W. Rawlings presiding. —The Hon. SECRETARY announced that the Annual Dinner would take place at the London Tavern on the 28th prox. Mr. HASLAM asked if any member

had been able to obtain uniform results when toning with hypo and alum. In reply, Mr. HENSEL thought that the success of the results varied with the brand of paper used. The negative also influenced the result, one with clear shadows being best. The temperature of the solution should be kept steady at from 120° to 130° Fahr. during the whole time of toning, which should take about twenty minutes. Mr. C. H. OAKDEN then gave a paper on the subject of

#### HALATION AND BACKING.

He showed that halation might be caused in two ways: first, by reflection from the back of the plate; and, second, by internal reflection from the molecules of the silver salt. The coarser the grain of the emulsion the greater would be this internal or lateral reflection, and so, by the same argument, the faster the speed of the plate the greater the liability to get halation on account of the greater granularity of the film. To overcome the halation arising from reflection from the back of the plate, many remedies had been brought forward, but at present he had found none to be perfect. The ideal backing should absorb all light; it should be easily removed, and should have no effect on the developer or plate. Mr. Oakden then reviewed some of the various forms of recommended backings. Gummed orange paper was not effective, partly by reason of the difficulty in getting optical contact. A slightly better suggestion was that of purple-bronze paper stuck on with glycerine. Carbon tissue was fairly effective. Bitumen or asphaltum had been highly recommended, but he did not find it to be so good as was claimed. A great number of formulae had been given, in which the chief ingredients were collodion and various aniline dyes. Of these some were better than others. Complaint had been made of the difficulty of removing collodion backing, but this was easily done by the aid of Monkey Brand soap. The speaker thought that there was yet much to be done in finding some convenient vehicle for holding colouring matters as light-absorbers. A mixture of caramel and sienna formed the most effective backing we have at present, but not even this has stood the test in certain difficult cases. As an example of a difficult subject, he mentioned the interior of St. Bartholomew's, Smithfield. He knew of no backing which had been effective in that place. With regard to the backing of lantern plates, he had found anti-halation pads effective for this purpose. Mr. Oakden then showed, by means of the lantern, some results of the tests made with various backings. Mr. FORT described some experiments which had been made by Mr. R. Beckett and himself about two years ago, to find out the comparative values of alleged halation remedies. The result of the experiments showed, among other things, that mixtures of caramel and sienna were effective alone, in proportion to the amount of caramel therein. Caramel used alone, and allowed to dry, was found to stand a very severe test, and prevent halation completely.

**Aston Photographic Society.**—The last meeting of the above was devoted to an exhibition of trade novelties. This is one of a series of similar ideas organized by the Committee of the above Club. The show on this occasion was taken up by Mr. William Tylar, who has made himself so indispensable in the realm of all amateur photographers. He made a capital display, and finished by showing how his patent acetylene lantern lamp behaved in the lantern, as contrasted by the ordinary oil lamps in general use. The thing was a great success, and much approval was elicited as to its simplicity and soundness. Not less interesting was the account given by his active manager, Mr. A. C. Townsend, as to the rise and progress of Mr. Tylar's trade, and many amusing anecdotes were related connected with a novel calendar which he issued years ago, and which humorously mapped out to the amateur a regular weekly routine. After this Mr. Tylar showed the rough models from which his later patents and designs had been produced, and the evolution of articles elicited the remark in the room that Mr. Tylar must certainly be a veritable modern Darwinian. Quaint incidents of trade, related in Mr. Tylar's inimitable style, concluded a most enjoyable evening.

**Leeds Camera Club.**—January 11.—Mr. G. THISTLETHWAITE, of the Bradford Photographic Society, delivered a lecture on

#### WITH CAMERA AND CYCLE IN LAKELAND.

with limelight illustrations. There was a large attendance of the members. The Lake district, said Mr. Thistlethwaite, was one of intense interest to every one, either on a holiday tour or from a photographic view, and it was an undoubted fact that the people of Bradford appreciated its beauties probably to a greater extent than some of their neighbours, and the series of views he should put before them would, he felt no doubt, create a greater interest, if necessary, among his audience to see the district for themselves. To get there it was perhaps best to take train to either Skipton, Morecambe, or Ingleton, and from either centre it could easily be reached in a day with the cycle. He found Ambleside one of the best places to stay at, as from there the several districts could be easily got to, and you are able to get back again in the evening. To obtain precise information, he recommended *Badderley's Guide* as the best, for with it no one need fear taking any of the paths or missing any point of interest. Taking the road from Ambleside towards Conistone, a very fine view of Windermere is opened out, and following on Langdale Pikes. A delightful though difficult subject for a photographer is next before you, and the remarkable echoes near Dungeon Ghyll will be well worth a visit to be heard. Down Red Bank into Grassmere, the grave of Wordsworth can be seen, with charming bits constantly cropping up, and following on to Rydal, at one time the home of Wordsworth, and the whole place so teeming with poetic recollections that the average visitor is very soon, said Mr. Thistlethwaite, humorously, endeavouring to burst into poetry on his own account, and, when he gets the fever, will have it badly. Taking another route from Lakeside Station to Bowness, many interesting and beautiful views may be had, and by taking the left-hand road from Thirlmere the finest view of Helvellyn is obtained. From Keswick, with its quaint market-place, the fine view from Castle Hill must not be missed; and Scawfell, Honister Pass, with the Falls of Lodore, are within easy distance. Mountain-climbing, really difficult and attended with no small degree of danger, can be indulged in by those who desire it, and the actual climbing was beautifully illustrated by a series of slides, which had been lent to the lecturer by a personal friend.

**Plymouth Photographic Society.**—January 13, the President (Mr. H. S. Hill) in the chair.—This meeting inaugurated the spring session, and, after the transaction of ordinary business, one of the Royal Society's papers, on

#### ARCHITECTURAL PHOTOGRAPHY,

by Mr. H. W. Bennett, F.R.P.S., was read, and some excellent slides illustrated the subject. The author treated the subject in an instructive manner, dealing in turn with subjects, lenses, cameras, swing backs, rising and falling fronts, tripods, plates, and exposure, and diagrams were shown to make some of the points clear. A discussion ensued, one member saying that, while it could not be denied that Mr. Bennett had shown some excellent results, he could not help noticing how very much the advice he had given differed from that of other well-known architectural workers. The opinion was also expressed that the lecture was not up to date, inasmuch as no mention was made of the Sanderson camera, Sandell plates, and persulphate of ammonia—a chemical which might be used with beneficial results to the windows of interior negatives.

**Edinburgh Photographic Society.**—Wednesday, January 10, Mr. A. Eddington, F.J.I. (President) in the chair.—The CHAIRMAN drew attention to the forthcoming Exhibition which opens on February 4, at which there are three gold medals, also silver and bronze medals and certificates of merit, to be given. The medals will be struck from the Society's new die, which has been specially designed for the occasion. A paper on

#### PICTORIAL PHOTOGRAPHY: ITS DIFFICULTIES AND PLEASURES,

was afterwards read by Mr. JAMES BURNS, H.M.I.F., who dealt with his subject in a clear and highly instructive manner, illustrating the various points by a large number of most meritorious slides. Mr. Burns, who is a medallist in the photographic art, also used a number of slides to illustrate certain defects. This procedure was much appreciated by a large and enthusiastic audience.

#### THE ROYAL PHOTOGRAPHIC SOCIETY AND PROFESSIONAL PHOTOGRAPHERS.

To the Editors.

GENTLEMEN,—In your last issue Mr. T. C. Turner takes exception to some remarks of a previous correspondent on the above question, and in much that he says I entirely concur with him. There are, however, one or two points upon which I am desirous of making a few observations based on fact and experience.

He complains that a certain section of photographers misrepresent the professional in putting him down to be an individual of sordid motives, and suggests that it would be to the public interest if the professional received greater encouragement at exhibitions, increased opportunities for comparison, and the raising of that spirit of emulation so essential to all high endeavours.

That is true, but the change cannot be made from without, it must spring spontaneously from within. Is it for photographers in general to go to the professional in particular and encourage or raise his enthusiasm for the purpose in question? If it is, then one might just as reasonably try to knock down the Great Pyramid with a tack hammer. The professional has no time to take any part in public affairs, whether of exhibitions or otherwise, having already too much to do in his own business. At least, that is what he says or what his actions imply.

In connexion with our Yorkshire Photographic Exhibition at Bradford, we invited all the principal professionals of the city to act on our com-

mittee. Not one of them responded by putting in an appearance. Had they done so, and shown a reasonable interest in an important event, it is possible, if not probable, that some variation of our general policy might have taken place in favour of professional portraiture as it is recognised by the general public. But our experience I know to have been the case elsewhere, nay, everywhere. Professional photographers, and by this term I am content to accept Mr. Turner's distinction of the largest and best, with rare exceptions, will not unite, nor make their influence felt for the well-being of photography as a whole. How, then, can they expect, while this is the state of affairs, when their apathy to all interests outside the immediate limits of their own businesses is well known to all, that others will go out of their way to coax a body of men to do what is very obviously their duty?

It is for professional photographers to raise their own enthusiasm of emulation, and not to expect that others will do it for them.

Mr. Turner then puts the extreme case of a lover of nature, possessed of illimitable leisure and independent of monetary cares, and proceeds to compare him with the hard-worked professional face to face with an exacting public. Where are those possessed of illimitable leisure and independent of monetary cares? They can be almost counted upon the fingers of one hand. The vast body of prominent amateur photographers is composed of men whose photographic work is done in spare moments, snatched from a busy commercial life, simply for love of it.

When Mr. Turner suggests that the Judges at photographic exhibitions are at fault because their verdict does not correspond with that of the general public, he is putting, I am sure, the accent on the wrong syllable. Are we to let our standard be fixed by a few highly cultured specialists, or by a fickle public, devoid of education and taste, rushing after fashions rather than seeking perfection?

It may be too venturesome a statement to make, and it is possible that I am deceived in my views, but I think we shall not have much longer to wait for a more or less complete renaissance of portrait photography. The ordinary photograph is becoming more and more a drug on the market. That photographers are aware of this is evident by the way they constantly reduce their prices. Our photographic exhibitions are doing much to educate the most enlightened section of the public, and, once they begin to emphatically demand better work, the rest of the world will follow suit. Then only the higher ranks of professionals will be able to maintain themselves, and the others will go to the wall.

Let me say, in concluding a somewhat rambling letter, that if Mr. Turner would become a contributor to exhibitions he would find his work received with open arms. We want men of his stamp to attach themselves to all movements for the progress of photography, whether as an art or as a business.—I am, yours, &c.,

PERCY LUND.

Bradford, January 16, 1899.

#### PHOTO-MICROSCOPY FOR WINTER EVENINGS.

To the Editors.

GENTLEMEN,—I was very much pleased with the suggestion which you made a fortnight ago, under the heading "Photo-microscopy for Winter Evenings," to the effect that with an ordinary camera and a short-focus rectilinear lens photo-microscopy could be done.

I welcomed the happy thought as a pleasant relief to the now dull monotony of lantern-slide making and bromide-paper printing; and as I had a good half-plate camera, extending to 16 in. and a  $\frac{3}{4}$ -in. focus lens, all I should want to complete my outfit would be a bull's-eye condenser, a good paraffin oil lamp, and a few microscopical slides, such as you recommended. Being enthusiastic on the matter, I very quickly obtained these, and at once set to work. I had considerable trouble, however, in fitting up a frame to carry the microscopical slides, as it required to have an easy motion towards and from the lens of the camera. With the camera fully extended to 16 in., the first object I tried was one of those suggested by you—the proboscis of a fly. After much manoeuvring I succeeded in getting the object evenly lighted, and focussed and centered on the ground glass; but I was rather surprised and disappointed at the extreme smallness of the object as enlarged on the ground glass, for it was only a little over half an inch long. I next tried the wing of a bee, quite a large object, but not a trace of the hooklets was visible on the ground glass to the naked eye. This was very discouraging; in fact, it was a mere travesty of photo-microscopy. I worked out the matter by the well-known formula, and found that the greatest magnification I could get out of my camera was  $\frac{3}{4}$  diameters. I am sure this statement must bring a broad sarcastic grin to the face of every experienced photo-micrographist, who is accustomed to working up to hundreds, and frequently to thousands of diameters. My decided opinion is that nothing but vexation and disappointment await on those who attempt photo-microscopy without a good substantial microscope, and a set of first-class objectives, ranging from a 2-in. focus to a  $\frac{1}{4}$ -in. oil immersion.—I am, yours, &c., J. B.

#### MARKING PRINTING PAPERS.

To the Editors.

GENTLEMEN,—As Mr. Watkins has called attention to the trouble of distinguishing plates, may I suggest that cut bromide and platinotype

papers are equally confusing in the dark room? I am quite aware of the ordinary methods of distinguishing the plain from the prepared surfaces, but in the dark room the senses both of sight and touch are enfeebled after a time, and it would save much trouble and waste if a spot or line were printed on the back of these cut pieces; and less waste would not tell against the manufacturer's interest in the long run, I imagine.—I am, yours, &c.,  
H. N. G. B.

January 13, 1899.

#### MINERALISED METHYLATED SPIRITS.

To the Editors.

GENTLEMEN,—I think it is due to your numerous readers that the erroneous and misleading statement made by Mr. Thomas Lowry in his article on "Methylated Spirits," which appeared in your issue of the 6th inst., should be corrected. He states that mineralised methylated spirit is quite unfit for photographic purposes. He does not, however, mention a single photographic purpose for which it is unfit. I am an operator in one of the largest, if not the largest, photographic establishment in the United Kingdom, and we use this mineralised methylated spirit for every purpose for which spirits of wine are required, including our extensive wet-collodion lantern-slide work, and we find it quite as good as the spirits of wine we used years ago, which had no mineral oil in it. There is no doubt about the methylated spirit we use being mineralised, for it turns as white as milk on water being added to it.—I am, yours, &c.,

JAS. BISSET.

4, Rosefield-street, Dundee, January 14, 1899.

#### THE HASTINGS EXHIBITION.

To the Editors.

GENTLEMEN,—I shall be glad if, with your usual courtesy extended to officials of photographic societies, you will allow me to draw the attention of your readers to the fact that entries for our Exhibition close on January 31, and that frames, &c., must be sent in not later than February 17. We have had a large number of inquiries, which promise a good show, and, as we have not had a similar Exhibition for nine years, the inhabitants of the town and neighbourhood are likely to take a lively interest in our efforts.

Mr. Wilson Noble, our former M.P., and Viscount Maitland have kindly consented to judge.

A special feature of the Exhibition will be a series of lantern lectures, which will be held in a separate adjoining room during the Exhibition.—I am, yours, &c.,

A. BROOKER, Exhibition Secretary.

21a, Wellington-place, Hastings.

#### THE INCANTO PURIFIER.

To the Editors.

GENTLEMEN,—In your issue of the 13th inst. we notice you have kindly printed a letter from Mr. W. F. Slater, calling attention to our Incanto purifier.

We have to thank him for troubling about the matter, as, in the pressure of business, we had not noticed your report.

May we add that our purifier was in use throughout the Acetylene Exhibition at the Imperial Institute, where it was generally pooh-poohed as unnecessary.

Your readers who visited the Hackney Photographic Society's Exhibition also had an opportunity of noting its efficiency, and the certificate which was awarded us proved the success of this invention when used with the Incanto generator.

We enclose herewith particulars of the apparatus, which has been duly patented, and our excuse for troubling you is that we do not think it quite fair that German apparatus should have all the prominent notices while English ones are overlooked.—We are, yours, &c.,

THORN & HODDLE.

1, Tothill-street, Westminster, S.W., January 16, 1899.

### Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 21, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

#### PHOTOGRAPHS REGISTERED:—

French & Co., 1, Railway-terrace, Walsington.—Photograph, entitled "Breakfast Time."

Wm. L. Shrubsole, 69, Grove-road, Norwich.—Photograph of Royal party, taken at the reopening of Sherbourne Church, Norwich.

RECEIVED.—CINEMATOGRAPH; J. M.; SPOTTER; F. C.; J. P. G.; and others. In our next.

E. W. P.—Mail not's address is Ayr, N.B.

H. CAMPBELL.—Messrs. Adamson, Eldon-street, Finsbury, E.C., supply such lamps.

W. G. ORME.—The address of the Photo chromoscope Syndicate is 119, Shaftesbury-avenue, W.

A. G. BUTERELL.—We believe Messrs. O. Sichel & Co., 62, Bunhill-row, E.C., supply the paper.

BACKGROUND.—DISTEMPER asks: "Will you kindly recommend a book on background painting?"—No such book is published.

HYDROQUINONE DEVELOPER.—A. U. ENDACOTT. Formulae for concentrated hydroquinone developers are given on page 994 of the ALMANAC.

C. N.—Address the Aerograph Company, 30, Memorial Hall, Farringdon-street, E.C., and the Polytechnic School of Photography, 309, Regent-street, W.

R. O'H.—We are doubtful if the slides are still made in this country, but, if you address Mr. W. I. Chadwick, 26, King-street, Manchester, he will tell you definitely.

S.—We should think your experience unusual. We have used the same firm's preparation, older than yours, and having visually the same appearance, without finding that it had lost its reducing power.

Y. Z.—It is, we believe, a silver print, coloured from the back, mounted on a metallic support, and given a hard glaze. We are unable to give the precise details of the process. As you probably know, they are produced by the Craotint Company, Kentish Town, N.W.

F. S.—We should scarcely call the work first class, that is, equal to the best produced; but Nos. 5, 6, 10, and 11 are very good indeed, No. 10 especially so. In the others the lighting is not good, and we should not class them as good likenesses. But, judging you by your best, you appear to be capable of doing very good work indeed.

LENS.—GOLFER. In view of our remarks last week, the Rev. J. Carter Browne, D.D., writes as follows: "It may interest 'Golfer' to know that, in the sixties, many amateurs were using a very good French lens by Darlot. In fact, I had a picture in the 1862 Exhibition taken by a lens of this make. I believe that some of them were minus the maker's name. Possibly your correspondent's lens is a Darlot."

ACETYLENE.—W. BEALES. Calcium carbide in small quantities may be obtained from any who supply acetylene apparatus; but we should advise you to be very careful in your experiments with your extemporised apparatus. Many fatal accidents have resulted from experimenting with extemporised or experimental apparatus by those who do not understand the properties of what they are dealing with.

E. D. FAWCETT.—Obviously the maximum illumination and covering power are required in such a slow process, hence our advice. With regard to formulae, none that have been successfully tried in this country are available. For the most reliable information we recommend you Herthier's book on *Photo-chromie Intéressante*, published by Gauthier-Villars, Quai des Grands Augustins, Paris. It is, of course, in French.

GUM BICHROMATE.—S. THOMPSON writes: "I have been much interested in reading about the gum-bichromate process, and I have just tried it, but cannot get the image to develop, even with a brush. I have worked according to Mr. Packham's method as given in the ALMANAC—well, not strictly to it, for I used office gum, as I have read that answers as well as the gum arabic, and it is much more convenient to me, and I should say to most people also."—In reply: We have little doubt that the failure was caused by the use of office gum. Commercial "office gum" is a very indefinite compound, often quite devoid of any gum whatever. We should recommend our correspondent in future to work with what is recommended, namely, the best gum arabic.

THE LATE ECLIPSE.—T. MATHIAS writes: "I was surprised to read in your Ex Cathedra of last week that the recent eclipse of the moon was disappointing in this country, whilst here (North Pembroke-shire) the sky at the time of the eclipse was exceptionally clear. The moon was of an orange-red colour, standing in relief among the sparkling stars against the deep blue sky, making a most magnificent sight. Now, could I, with an 11-inch Cooke lens, take a photograph of an eclipse that would be of any value? If so, what plate to use, and what exposure would be required?—The photograph would, of course, be very small, but, if good, would be interesting. Any plate with a fine grain would do, but it should be backed. The exposure would depend upon the brilliancy of the moon. If it were an orange red colour, more exposure would be required than if it were of its normal appearance. By a few experiments with exposures on the moon, with the plates that are to be used, a day or two before, the proper exposure will be ascertained.

PLATINOTYPE PRINTING.—TOM REVELLY says: "I have noticed in this week's JOURNAL your two correspondents' troubles ('Platinotype' and 'Platinotype Printer') re the Platinotype Company's A paper. For several months I have been worried with exactly the same trouble. I nearly always get the coarse line, as well as extreme meanness. I have written to the Company, and they say the cause is insufficient development. This cannot be so, for I have left prints in the developer for fifteen minutes at a time, and they have been as badly marked as the others. Damp is also not the cause, or the colour of the prints would suffer. I have no difficulty in getting pure, cold, black tones. Perhaps some of your readers can help us in this trouble. I have used both the Company's D salts and oxalate of potash at every possible strength, from a saturated solution downwards. I have also tried old baths, and part old part new, also a perfectly new bath, all with the same result."—In reply: Some correspondent may help with a suggestion that will avert the trouble complained of.

\* \* Owing to great pressure on our space, several articles, Editorial Table, and other communications are unavoidably held over.

### EX CATHEDRÂ.

WE are officially informed that, although the regulations and terms affecting the question of taking photographs at the Paris Exhibition of 1900 have not yet been definitely settled by the Commissaire-Général, no monopoly will be granted, and photographers of every country taking part in the Exhibition will be allowed to practise their art on equal conditions and terms of payment.

\* \* \*

PROFESSOR CLEVELAND ABBE, in an American contemporary, recently dwelt upon the advantages which German scientific investigators possess over those of other countries by reason of the excellent national system of training so long in force in the Fatherland. He points out that a mistaken idea has widely prevailed that the investigator is a genius, born and not made. The history of German science has, however, shown that environment and training are as important as birth and inheritance. The whole system of education in the German universities has for five generations been directed to the development of the investigator as its highest product. Those who discover important new facts, laws, or principles, have been

rewarded with the highest places in the intellectual world of that nation. Those who feel that they have a desire or calling for scientific research are encouraged to study for the degree of doctor of philosophy, a degree that is only granted when the candidate has, by actual observation, experiment, or exploration, made some important contribution to human knowledge. The professors under whom he studies have, in their turn, made many similar contributions, and are well prepared to judge of the value of his work. The German universities have, during the past seventy years, published over 50,000 so-called "doctors' dissertations," embodying the results of the works of 50,000 candidates. The consequence is that to-day Germany easily leads all the world in the amount and value of her contributions to human knowledge and the energy with which her students pursue the study of nature. What the Professor here says with regard to science in general applies with equal force to photographic science in particular. The facilities for studying photography scientifically and systematically in Germany, as we have many times before pointed out, find no parallel in Great Britain, where private effort, almost entirely without state aid, has to take upon itself the responsibility of maintaining and encouraging original investigation work. The munificence of Dr. Ludwig Mond established the great physico-chemical laboratory in Albemarle-street the other day; but things of this kind should be done by the State and not left to private initiative. In not a single one of its aspects does photography owe the least encouragement to the State. Far different is the case in Austria and Germany, as the establishments presided over by Eder and the late Dr. Vogel abundantly testify.

\* \* \*

SEVERAL times of late the hydrofluoric acid method of stripping films has been referred to, and the inconvenience attending its employment objected to. But for these there is no question that the fluoric acid method is the best; the inconvenience is, however, much increased by using the acid solution much stronger than is really necessary. Most of the published formulæ are unnecessarily strong. Of course, the stronger is the solution the sooner is the film loosened, also the more the fumes from the acid pervade the place. Half a dozen drops of the commercial acid, or less, per ounce of water will suffice, if a little longer time be given, and then there will be less fumes to pervade the apartment and act upon the vitreous matter about.

There is one caution we may give with regard to the use of fluoric acid, which we do not remember having seen given before. Some of us have, unfortunately, to use spectacles, the glasses of which will in a short time become dimmed with the fumes of the acid, and there is no means of cleaning off this dimness without repolishing the glasses; therefore, when working with fluoric acid, an old and disused pair should be worn when using this method of stripping. For the same reason all photographic lenses should be put away secure from its fumes when employing fluoric acid. Glass exposed to the fumes of fluoric acid makes the finest ground glass that can be made for focussing screens, and this shows how necessary it is to protect our spectacles from its action when working with it.

\* \* \*

As will be seen in our issue of last week, Herr R. E. Liesegang, in our contemporary, the *Photographische Correspondenz*, points out the advantages of exposing plates from the back, and claims that the results are similar to those obtained on multiple-coated plates. There is another advantage gained by this system of working, namely, the avoidance of halation from the back of the plate. This we have more than once pointed out with reference to the taking of reversed negatives for collotype and other mechanical processes in which reversed negatives are necessary. It is a common practice with process workers to take the negatives, whether by the wet-collodion process or on dry plates, through the glass, thus avoiding the use of a prism or reversing mirror, and at the same time avoiding halation, so prevalent when dealing with strong contrast with gelatine plates.

\* \* \*

AFTER ten years' service to the Hackney Photographic Society as its Honorary Secretary, Mr. W. F. Fenton-Jones retires from that position at the end of next month. Such a record of gratuitous and uninterrupted devotion to the interests of a photographic society is almost, if not quite, unique—at the moment, at any rate, we are unable to recall an instance in which Mr. Fenton-Jones is outdone as to length of years in office. That gentleman was one of the founders of the Hackney Photographic Society, and he has the satisfaction of knowing that the work he has accomplished on behalf of his Society has not been without its beneficial influence on photography at large. Some of the ablest photographers of the day belong to the Hackney Photographic Society, whose annual Exhibitions, moreover, have for long ranked only second in interest and value to those of the Royal Photographic Society. In all this good and useful work Mr. Fenton-Jones has borne a leading and unselfish part, and we are glad to hear that at the forthcoming dinner of the Society he will be asked to accept a testimonial in recognition of his ten years' gratuitous efforts as its Honorary Secretary. Testimonialising is sometimes grievously overdone, but Mr. Fenton-Jones right richly deserves the concrete compliment proposed to be offered him, and we are sure it will not be unworthy of its recipient.

\* \* \*

REFERENCE was made last week to new regulations adopted at a recent meeting of the Pharmaceutical Society with regard to the sale of poisons as well as to the keeping of them. These new regulations seem to be highly necessary if one may judge from the careless way poisons are sometimes vended by those entitled to sell them—the Pharmaceutical Chemists—as often evidenced in the Coroners' Courts. At present the only ones

permitted to vend the poisons mentioned in the Poisons Act of 1868 are the Pharmaceutical Chemists, and the enforcement of the law, for its infringement, has hitherto vested in the Pharmaceutical Society. As we have frequently pointed out before, it has not been at all remiss in this direction in the case of photographic dealers, oilmen, and others, who happened to sell anything required for industrial or experimental purposes, if it is named in the Act, to secure their (the Society's) five pound penalty and costs; but how many prosecutions, it may be asked, has it instituted against members of its own body for infringing the law, even when flagrant cases have been laid before it by coroners and by the police authorities? Echo answers, How many?

\* \* \*

It may be remembered that last year a Poisons Bill was introduced into the House of Lords by the Privy Council, and was passed through committee, but by press of other business it suffered at the end of the session in the "slaughter of the innocents." This Bill, had it passed, would have taken the exclusive monopoly in the sale of poisons used for industrial purposes out of the hands of the Pharmaceutical body, as well as the enforcement of the law, as it provided that the Privy Council was to have the same rights as are at present vested in the Pharmaceutical Society. As the Privy Council have long seen the necessity for such an Act, there is every probability that the matter will not be allowed to rest. In Germany the control of the sale of poisons is vested in the local police, and with them rests the enforcement of the law, which, like most German laws, is very stringent, entailing, as it does in this case, heavy penalties or imprisonment. In Germany the sale of poisons is not restricted to pharmacists, but to licencees of the police authorities. Would it not be better that such a condition of things should obtain here with regard to the keeping and sale of such poisons as are required for industrial purposes? The police are better able to safeguard the public than the Pharmaceutical Society have hitherto done, as they would proceed against chemists for violation of the law as well as against photographic dealers, oilmen, &c. The German law regarding the sale of poisons commends itself to our Privy Council for consideration.

\* \* \*

THE Commissioner of Patents in the United States has given a decision which is of importance to applicants for patents in this country as well as in America. He holds that the date of application for an English patent is the date on which the original application was filed, even if it had been accompanied only by a provisional specification, the reason being that, according to English law, provisional protection is not analogous to a caveat, and the patent, when granted, is dated as of the day of application, instead of bearing the date of the actual grant or issue, as is the case in the United States and some other countries. A new statute came into force in the United States on January 1, 1898, which provides that a would-be patentee who had first applied for a patent in a foreign country will not be debarred from receiving a patent for the invention in the United States, by reason of its first having been patented abroad, unless the application for said foreign patent was filed more than seven months prior to the filing of the application in the United States. Those who apply for patents in this country, and desire to also protect their inventions in the United States, should therefore apply as promptly as possible in America.

It is announced that the business of the Eastman Photographic Materials Company, Limited, is now being carried on under the title of 'Kodak, Limited, successors to the Eastman Photographic Materials Company, Limited.' This answers many inquiries that have been addressed to us on the subject.

### SYSTEMATISED PRINTING.

WITHIN the last decade the principle of leaving as little as possible for guesswork or rule of thumb has by degrees almost reached the stage of a science. Our plates are marked with a fair approximation to an exact speed indication, thanks to the labours of the late Dr. Hurter and his colleague Mr. Driffeld; we have exposure meters innumerable which, at any rate, profess to give the correct exposure under any given circumstances; and, in a belated fashion (for the method was proposed ten years before it was adopted), every lens sent out has its diaphragms marked with numbers which, virtually, are applicable to all lenses, and number for number represent identical exposure values; but, when we criticise printing methods, what do we see? A negative is put out to print, and it is examined at intervals to see how it is getting on. Where large numbers of frames are put out to print, we see in some establishments a certain amount of grading of their printing values, and putting similar grades in batches, which are all exposed and turned down at a time; but how many photographers refer their negatives to a particular standard, and classify and label them in accordance? We remember its being narrated in these pages how a certain well-known expert operator, in the times when lenses were few, prided himself upon his knowledge of the working rapidity of all known lenses and all their stops, such knowledge being looked upon as special and unusual; but nowadays the merest schoolboy has only to look at the diaphragm numbers and he is able to use a dozen different lenses with a uniform illumination, thanks to the "Uniform System," universally shortened into "U.S.," this name and abbreviation being adopted from a suggestion of our own at the time the system itself gained the sanction of the Royal Photographic Society. In the same manner the working value of a printer is largely influenced by a reply to the query, "How many printing frames can he attend to?" We say that such a standard ought to be as much out of date as that of the operator and his lenses we refer to. We go further, we say that, with a young lad to read his indicator or meter, there is no reason whatever why a blind man should not undertake to do wholesale printing and attend to twice or thrice the number of frames an expert printer is now expected to undertake. It will, of course, be understood that we refer to plain, straightforward printing, where no shading or printing-in is needed. When it comes to a question of artistic printing where one part of a negative which is too weak requires less printing, and another over-dense portion has to be exposed to light action for a longer period, we do not deny individual attention. Artistic taste and skill is needed then, photography cannot be reduced to the level of mathematics in such cases—a fortunate thing, too, it is for the professional photographer that in this, as in other departments, artistic fingers informed by experienced brains are needed; otherwise "their occupation is gone."

But to return to practical, every-day, straightforward printing. We would make a suggestion. There are meters to be purchased at a reasonable price, and graded for the particular purpose we are endeavouring to bring into use. If these,

moderate in price though they be, should be beyond the purse of the printer or small amateur, it is a very easy matter for every one to make a meter for himself by the method often described of pasting together layers, successively increasing in number, of either tissue paper or slightly coloured gelatine, and using it for classifying every negative he possesses. Suppose a meter of ten graduations—the first shade representing the thinnest, and the last the densest probable negative. All that is necessary is to put the meter and the negative to print at the same moment and to turn down the meter the same moment the print is turned down. The number of the tint is read, and is marked upon the negative. Taking it, say, for example, as tint 3, then all negatives of tint 3 may be turned down at once when the meter shows 3; the same with 1, 2, 4, 5, to the end of the series. Let our readers imagine for a moment what an immense saving of time, what exactitude of correctness of printing would be brought about by such means—the labour of numbering each negative the first time it was printed from would be looked upon as trivial in the extreme.

An objection may be urged that a standard paper, always uniform, would be needed. As a matter of fact, such paper can easily be made, and is indeed an article of commerce available to any one who likes to try it. A further objection might, with some colour, be raised, that the indications given by the standard paper might not be equally applicable to albumenised paper, P.O.P., and collodio-chloride paper; and the objection would, to a certain extent, be well grounded as far as it went. The number would only be applicable to one particular kind of paper, for it is well known that the quickness of printing of different kinds of sensitised paper varies enormously. Taking the 1 or 3 just referred to to relate to the P.O.P., it might need the meter to show No. 5 before the albumen was sufficiently printed. All then that would be necessary would be to add a letter, say, A, C, or P (the initials of the three common printing papers made) to be attached to the meter figures with which the negative was tabulated. When all three kinds are liable to be employed, all three initials, with their respective meter numbers, should be marked on the negative, and so the system rendered complete.

We think we have said enough to show the desirability of bringing printing operations into line with the more scientific method of procedure which characterises so many other branches of photography, and we strongly advise every one of our readers to adopt some one or other of the meters to be had or made, and so systematise the process of silver printing.

**Coagulation of Albumen.**—The employment of citric acid or citrates in the making of sensitised albumenised paper is well known, and some explanation of its function may possibly be found in the discovery of M. G. Halpden, published in the *Journal de Pharmacie*, &c., of the peculiar action of citric acid or a citrate in the coagulation of albumen. He finds that this coagulation is complete in the presence of citrate salts or ammoniacal salts.

**Defining Power of Lenses.**—In a recent discussion at one of the metropolitan societies, the question of the definition yielded by lenses was raised, and it was said that photographic lenses were not constructed to yield microscopic definition. That is so in the strict sense of the term, but the majority of them by the best makers, particularly those of the older forms, were so constructed that they would yield far finer definition than gelatine plates of the usual rapid type are capable of rendering, by reason of the coarse-

ness of the particles of silver that form the image. Where, then, it may be asked, is the necessity of the optician expending his skill to make lenses to give such fine definition when the plates to be used with them are incapable of doing justice to it, particularly when they can give us compensating advantages in other directions? There is no question that some of the older forms of lenses, when well constructed, do give finer definition than do some of the newer forms, that is, when used on plates—say wet-collodion or albumen—that are capable of recording it.

**What does it Mean?**—A correspondent sends us a card with a halfpenny affixed stamp which he has received through the post. It is as follows: "Blackwater, Hants" (no date). "Dear Sir, I shall be glad to have particulars of your life for the *Biographer*. Yours truly, ———," the address, the request, and the signature being in three different handwritings. Our correspondent says, "Fancy being requested through the halfpenny post to send 'particulars of your life' to an unknown individual." He adds, facetiously, that, "so far as I know, there is nothing in the particulars of my life that would interest the readers of publications either of the 'goody-goody' order or the 'penny-dreadful' type, or even, I am happy to say, the authorities at Scotland-yard, let alone those of the *Biographer*, if there is such a publication." He further says, "I am only a photographer, and, as I have never heard of such a publication as the *Biographer*, and it is not known at Smith's bookstalls, neither does it figure in *Sell's World's Press*, I ask if you can tell me what is the scheme? You have often told us about the 'free-portrait dodge,' so perhaps you or other photographers can tell us something about this affair?" At present, we cannot; but we do know that others, who are not photographers, have received similar cards requesting "particulars of their lives."

**Properties of Pure Carbide of Calcium.**—It is now well known that some, if not indeed all, the offensive smell of acetylene gas, as usually found, is owing to the presence of impurities, notably phosphorus, which, besides giving the unpleasant odour, confer also an element of danger upon the gas. M. Henri Moissan has described to the French Academy of Sciences the properties that should characterise pure carbide of calcium. When absolutely pure, it should be quite colourless and transparent. If any colour be shown, it is a sign of the presence of foreign matter, iron, for example, giving a reddish-brown tint to the mass. It is quite evident that as the present price of commercial carbide causes the gas to be too expensive, in most cases, to compete with coal gas, the pure form mentioned can only be looked upon as a chemical curiosity. Still there have been published methods of purification which, it is stated, leave nothing to be desired on the score of freedom from smell.

**Deodorising Benzole, &c.**—Acetylene is not the only material used in photography whose odour is sometimes a bar to its employment. Benzole would be more frequently used as a varnish basis but for its disagreeable smell. This is so peculiar and, in a way, unvarying, that it might be looked upon as a necessary characteristic; but, according to a foreign contemporary, it need be no longer so looked upon. Herr Beringer has devised the following method for deodorising benzene:—To a mixture of 1½ litres of sulphuric acid and 1½ litres of water add, after cooling, 30 grammes of potassium permanganate. Next mix with 4½ litres of benzene, and allow to stand for twenty-four hours with occasional shaking. The benzene is then siphoned off, and agitated for several hours with a solution made by dissolving in a litre of water 7½ grammes of potassium permanganate and 15 of sodium carbonate. It is stated that the benzene, when finally separated without distillation, will be quite colourless and devoid of odour. Should such a prepared benzole be placed upon the market, it is likely to have a ready sale for photographic purposes in many directions. We can readily believe in the possibility of this removal of smell when, to our knowledge, that usually most offensively smelling liquid, bisulphide of carbon, can be made absolutely free from smell, though it is true that, after being kept a while, there is apt to be a recrudescence of its original nature in that respect.

**Gale's Double Microscope.**—With regard to the inventor's account of the performance of this instrument a correspondent of the *English Mechanic* states that it does not appear to be different in principle to one described to the Royal Society in 1870 by Dr. Royston Pigott, who gave particulars of his observations on Podura scales, the usual interpretation of the latter being, he stated, incorrect; his results, however, were not reproduced by other experimenters, and were in consequence stated to be spurious and his theory incorrect. The writer of the letter found the matter interesting, but he was never able by means of the high magnification of the double microscope to obtain a differentiation that he could not obtain by other usual means.

## DEVELOPMENT, INTENSIFICATION, AND FIXING IN ONE OPERATION.

### III.

TAKING Mr. J. B. B. Wellington's formula as the starting point, the relative proportion of silver, sulphocyanide, and hypo may be left substantially the same, the quantity of water alone being decreased in order, for the sake of convenience, to make a more concentrated solution; or—and this I think the preferable plan—the proportion of hypo may be decreased in making the solution, and the exact quantity adjusted by the addition of a few more crystals to the mixture on trial.

Let the formula be set down as follows:—

Nitrate of silver.....	100 grains.
Sulphocyanide of ammonium .....	200 "
Hypo .....	150 "
Water .....	2 ounces.

I do not find it necessary to dissolve the salts in separate portions of the water, though it is preferable to dissolve the silver first, and, when dissolved, to add the sulphocyanide, which will at once cause a dense, curdy precipitate, which becomes less, though it does not wholly disappear, as the sulphocyanide dissolves. When the crystals of the latter salt have disappeared, or nearly so, the hypo may be added, and this will form a clear solution long before the whole is dissolved, and it might be supposed that the quantity of hypo is in excess of what is necessary; but, although in this state of concentration a very small quantity of hypo seems to make a clear solution, under those circumstances it will not bear the slightest dilution without forming a precipitate, whereas it is required to add only a few drops of the silver solution to a comparatively large volume of developer without causing any more than a very slight precipitate, and that not immediately.

Where, therefore, the solution has been made according to the above proportion, it may be adjusted in the following manner. If a single drop be allowed to fall into a large quantity of water, an instant opalescence will appear; but, if two or three drops be added to, say, a couple of drachms of water, there may or may not be an immediate precipitate according to whether the sample of hypo happens to be fairly dry or contaminated with a large proportion of water. It is this uncertainty as to the quality of the hypo that leads me to recommend this method of final adjustment. The object to be aimed at is to use only as much hypo as will prevent the formation of a decided opalescence for several seconds after dilution to the extent mentioned, which represents approximately the proportion in which the silver solution is to be added to the developer when it is desired to start intensification. If precipitation takes place directly the silver solution is dropped into the water, or within two or three seconds, then a few more crystals of hypo are added to the "stock," and shaken until dissolved, and the trial repeated until the mixture remains clear for at least ten seconds.

In this condition and used in the proportion of half a drachm of silver solution to two ounces of developer, the precipitation of the silver is very gradual, and as it is thrown down it comes under the power of the developer, and is at the same time reduced to the metallic state, and if the quantity of silver used is properly adjusted to the strength of the developer, every portion of it is deposited on the image in building it up on intensification. If too much silver be

used for the strength of the reducing solution, the developer will be rendered "muddy" from the too rapid precipitation, either in the reduced or unreduced state or both, and most of the metal will be wasted by deposition on the sides of the dish or loosely on the surface of the film. If the strength of the developer is normal and it contains the usual proportion of bromide, the colour of the precipitate will be dirty yellow or light brown, since it will consist of a mixture of bromide and sulphocyanide of silver in excess of what the solution is capable of reducing all at once to the metallic state. In such a case intensification proceeds in due form, but slowly, and eventually, if no more silver be added, the solution becomes clear once more, partly by reduction and partly by being taken up again by the gradually exhausted sulphocyanide and hypo.

The reducing action of the alkaline pyro, or whatever may be the agent used, appears to be exercised first upon the silver salt in the nascent condition, or in the act of being thrown out of solution. If it is thrown out in larger proportion than the reducing agent is capable of acting upon at once, a portion of it takes the form of a comparatively coarse precipitate, which retains that form until, by the gradual reduction of the more slowly and finely precipitated material, the solvents in the solution are left in a position to redissolve it. Then, under the reverse process of solution, it again comes within the power of the developer and intensification proceeds continuously. Thus it does not matter much if too much silver, in moderation, be added at once, since it eventually comes into use. The intensifying solution may, of course, be kept clear by the employment of a larger proportion of the solvents sulphocyanide and hypo; but then it follows naturally that a larger quantity of silver must be used in order to afford the necessary supply. In fact, the larger the proportion of hypo, especially, the slower will be the intensifying action, and the larger the quantity of silver solution necessary. The rapid and economical working of this intensifier seems to depend entirely upon the solution being adjusted to what I have already described as that state of "unstable equilibrium" that supplies the necessary quantity of silver just as it is required by the reducing solution.

So far I have spoken only of the employment of a reducing solution of normal strength, such as would be used for ordinary developing purposes, but by increasing the reducing power a much larger proportion of the silver solution may be added and dealt with at once, and the intensifying action not only hastened, but greatly increased, though at the risk of coarseness and unevenness of deposit. The chief beauty of the method lies in the fineness and evenness of the image formed when it is properly applied; but this, as in all other similar processes of deposition, entails a comparatively slow or gradual action. Moreover, going back to the title of this article, if we are to combine the operations of development, intensification, and fixing, or even the two first only, we are practically limited to the use of the normal developer and the minimum quantity of silver solution, since any increase in the reducing strength would cause inevitable fog unless a much larger proportion of the silver solution were employed, in which case fixing would take place before development commenced. There lies the difference between the Wellington process pure and simple and the modification I am describing. The former is intended only for use after fixing, and if used before would "clear" a collodion plate instantly, and a gelatine film, unless it contained a large proportion of iodide, long before the image had arrived at maturity.

In the earlier part of this series of articles I stated that it is quite practicable to combine the trio of operations in one, at least with collodion plates, but that I was doubtful about the application of the same method to gelatine. Since that statement was made I have turned my attention to gelatine, and find that, while it is possible, and indeed, by the exercise of some patience, easy to develop and fix with the same solution, the process is not a very useful one. For reasons already stated, it is necessary to keep the fixing strength of the solution down low enough to permit development to run its full course, and this, owing to the much greater thickness of gelatine films and the larger quantity of silver they contain as compared with collodion, makes the fixing operation a painfully long one, during which period intensification is going on continuously; in

fact, long before the film is fixed both development and intensification are complete, and when fixed, or at least apparently fixed—"cleared" we will say—the image has become hopelessly over-dense. Even then, looking at the very small proportion of fixing salts contained in the solution, it would be in the highest degree unsafe to trust such a negative to stand without further fixing in strong hypo; for which reasons we may dismiss the possibility of combining all three operations with gelatine.

But, if we confine ourselves to two, development and intensification, there are circumstances under which this method becomes extremely useful, whether with plates or films that have a natural tendency to thinness of image, or wherever, from over-exposure or the character of the subject, it is desirable to obtain greater density or contrast. Under any of these conditions the addition of a very small quantity of the silver solution to the developer will bring about a wonderful alteration in its behaviour. The addition may be made at the commencement of development, when the necessity for extra contrast is known or suspected, or at any later stage when that need is recognised. The quantity of silver used must, under these circumstances, be very small, not more than from five to ten minims in two ounces of developer; if added at the commencement the smaller quantity should not be exceeded. It is better, then, to commence with only one or two minims, and to add more if the progress of development shows it is permissible. The quantity of silver thus added to the solution may seem too small to produce any appreciable result, but it must be borne in mind that, as this is reduced, the solution feeds itself at the expense of the sensitive film, and, by dissolving minute quantities of silver bromide, keeps up a continuous process of intensification. Especially in cases of over-exposure this self-feeding process is valuable, because by attacking the surface of the film it dissolves away the feeblest portions of the impression, and thus helps to prevent the clogging of the shadows that always follows over-exposure. For the same reason it is better not to add the silver solution on commencing development except it be desired to create contrast, as, for instance, in black-and-white or "process" negatives. In the latter connexion I believe it will be found especially valuable, as, where the exposure has not been needlessly curtailed, practically any density can be obtained without the least risk of fog; on the contrary, the addition of the sulphocyanide and silver solution gives a clearer result than when it is not employed, owing, no doubt, to its solvent action on the surface bromide. Of course, a line must be drawn between fog by reduction and the deposition of a dirty deposit that can be rubbed off the surface of the negative; this will often occur both on back and front of the plate, and present anything but a pleasing appearance; but it is easily rubbed off, leaving the shadows absolutely clean.

Applied to gelatine films simply as an intensifier after fixing, I have no hesitation in saying that this method will give an equally good result in the same or, if desired, a much shorter time with a less expenditure of silver. I have already mentioned that, by increasing the reducing power of the solution, a larger proportion of silver can be added and the operation rendered more rapid. Obviously, after fixing, we are not limited as to the proportions either of pyro or ammonia that may be used without causing fog, because there is no silver in the shadows to reduce, and any that may be thrown down from the solution by abnormal action remains either in suspension or is deposited evenly on the film in a loosely adherent manner that leaves it capable of removal by friction. Intensification proper only takes place on the image already existing; consequently, by adding small successive portions of silver solution to a strongly alkaline solution of pyro, intensification proceeds rapidly and with a minimum of silver. I can get more than necessary density on a half-plate previously too thin to print with the expenditure of half a drachm to a drachm—the latter in case of extreme thinness—of the above solution, which means from three to six grains of silver nitrate; with the Wellington formula, two ounces of intensifying solution would contain nearly forty grains of silver. In using the process in this manner, after fixing and slightly washing the film, I "squirt" into the developer, by means of the dropping tube, half a drachm or a drachm—the quantity does not matter much, so long as it is sufficient—of ammonia solution, the same or

rather less of ten per cent. bromide, and, last of all, about ten minims of silver solution, and go on adding more of the latter till density is obtained. Bromide in this case acts as an accelerator by putting the silver in a more easily reducible condition.

W. B. BOLTON.

### PRINTING OUT.

CHLORIDE of silver printing-out paper contains a considerable addition of free nitrate of silver. This is necessary, as the pure chloride of silver would otherwise give too weak an image. The silver nitrate is looked upon as a chemical sensitiser, and as an absorber of the chlorine liberated from the silver chloride during exposure. If this reaction really takes place, then there must be less silver nitrate in the exposed, as compared with the unexposed, parts of the film. I have observed a number of phenomena which indicate that this actually takes place. They seem to me worthy of enumeration, since they may explain various facts. I have already drawn attention to one of these phenomena in the *Photographische Correspondenz* (1898, p. 9) as follows: A plate of glass was coated with a solution of gelatine containing gallic acid. When set, a gelatino-chloride print was placed in contact with it. The print developed to full strength, and upon its removal a negative image of the print was observable upon the film of gelatine and gallic acid. The silver nitrate had by diffusion passed from the print into the gelatine film, and been then reduced by the gallic acid. I left the explanation of this phenomenon an open question. It is very probable that no diffusion took place under the fully exposed parts of the print, because little or no silver nitrate was there to diffuse, as may appear from the following considerations.

A similar observation was also made when a gelatino-chloride print was placed in contact with a gelatine film containing chloride of soda. A negative image then formed of chloride of silver.

But it is not necessary to use jellies to observe such variations in diffusion at the exposed and unexposed parts of a print. If a printable gelatino-chloride plate is immersed in a platinum toning bath which contains a little chloride of soda, those portions of the film which have received little or no exposure to light will be covered with a deposit of silver chloride, and the dark portions of the plate will not be thus affected. This freshly formed chloride of silver is on the surface of the film and may easily be removed by friction. (If we adopt the theory as true that the amount of free silver nitrate diminishes with exposure to light, the variations in diffusion are easily explained according to the propositions I have formulated in my work on *Chemical Reactions in Gelatinous Substances*, viz., that silver nitrate can only pass from the film if its solution is molecularly superior to that of the chloride.) Similar deposition may be observed upon the unexposed portions of a chloride print when it is immersed in a gold bath with little or no previous washing. It is not even necessary to study the behaviour of plates and papers when immersed in baths in order to find these peculiar phenomena of diffusion. I came across a number of old unfixed albumenised paper prints, which had been stowed away in the dark for years. It is well known that the backs of such prints turn brown after long keeping. This discolouration may be traced to a reaction between the free silver nitrate and the organic matter of the paper. In these prints the discolouration was absent from the back of the paper at those parts where the print was deepest. On the other hand, the high lights of the print corresponded with the dark areas on the back, which had the appearance of a vigorous negative. The phenomenon is easily accounted for by the theory I have put forward above. The silver nitrate had diffused into the paper; but, as it had been used up in the fully exposed portions of the picture, the corresponding portions of the back had not turned brown. Similar negative images may be found under certain conditions upon the backs of physically developed chloride prints which have received short exposure, and may be similarly explained. I have observed them when prints have been left in the dish a considerable time without rocking and with only sufficient developer to keep them moist. Under normal conditions these phenomena never occur. The possibility of solarisation with physical development may also be inferred from the deficiency of silver nitrate from the fully exposed portions of the image. It is known that gallic acid is not the developer in this case, but nascent silver, and it is difficult to understand why intensification should not take place; but I have noticed that strongly exposed parts, such as the unprotected margins of prints from dense negatives, do not blacken further. This may be taken as the beginning of solarisation, as other portions which have had much less

exposure become much denser. In the collodion process something similar is also possible.

In conclusion, I may mention an experiment for estimating the distribution of silver nitrate in a visible chloride of silver print. If albumen is brushed upon such a print, it should be coagulated by the silver nitrate in the unexposed parts, and it should remain unaffected where full exposure has taken place. One might expect the formation of an albumen relief. I have not, however, obtained any results yet that might be of practical importance.

DR. R. ED. LIESEGANG.

### SACCHARINE AS A SENSITISER.

HERR E. VALENTA points out, in the current number of the *Photographische Correspondenz*, that saccharine forms dyes with phenols and amidophenols which are very similar to the phthaline dyes.

Sacchareosine, or saccharine of tetrabromoresorcin, is a brownish-red powder which is not very soluble in water or alcohol, but readily dissolves in alkaline solutions with a carmine-red colour and a greenish-yellow fluorescence; it is very soluble in ether and gives a reddish-yellow solution, with less fluorescence. Its solution has a faint alkaline reaction. The addition of hydrochloric acid turns the red aqueous solution yellow, and the fluorescence disappears; but both the colour and the fluorescence are restored by the addition of ammonia in excess. The dye is quite insoluble in benzole.

For sensitising plates a preliminary bath of—

Water .....	830 c. c.
Alcohol .....	200 „
Ammonia .....	15 „

was used, and the sensitising bath was—

Water .....	800 c. c.
Alcohol .....	200 „
Dye solution (1:500) .....	100 „
Ammonia .....	15 „

This dye gives a vigorous band from D to D  $\frac{3}{4}$  E, with a maximum at D  $\frac{3}{4}$  E.

Saccharine of diethyl-m-amidophenol is a green powder, with metallic lustre, insoluble in water, but easily soluble in alcohol, with a red colour, and has a magnificent blood-red fluorescence; alkalis and ammonia immediately destroy the colour. The dye is insoluble in ether and benzole.

For sensitising no preliminary bath was used and the ammonia was omitted from the sensitising bath, which was otherwise as above.

This dye gave two bands, a narrow one with maximum at D, and a broad but much weaker one with the maximum at D  $\frac{3}{4}$  E.

The acetylated product of the above dye is a greyish-violet powder, greenish metallic lustre, and is soluble in water, alcohol, alkalis, and ammonia, with a violet-red colour, and very brilliant blood-red fluorescence which is most marked in dilute solutions. Hydrochloric acid alters the colour of the aqueous solution, and destroys the fluorescence. It is slightly soluble in ether with reddish-yellow fluorescence, and is insoluble in benzole.

For sensitising, the ammoniacal preliminary bath is used, and the sensitising bath is the same as given above. It gives a vigorous band from C  $\frac{3}{4}$  D, to D  $\frac{1}{4}$  E, with a maximum at C  $\frac{3}{4}$  D, and with long exposure a second weak at D  $\frac{3}{4}$  E.

Sulphurine of diethyl-m-amidophenol is also a violet-brown powder with green metallic reflex, easily soluble in water and alcohol with deep red colour, it has an intense blood-red fluorescence which is more brilliant with an addition of ammonia. Hydrochloric acid destroys the fluorescence. It is soluble in ether with a new red colour, and yellowish red fluorescence, it is insoluble in benzole.

Used, as suggested above, with preliminary bath it gives a vigorous band from C  $\frac{3}{4}$  D, to D  $\frac{1}{4}$  E, with a maximum at D, and a second, weaker and broad band with the maximum at D  $\frac{3}{4}$  E, which, with long exposure, almost fills up the gap to beyond E.

This dye has also the advantage that it is very easily washed out of the gelatine. The saccharine of diethyl-m-amidophenol is readily destroyed by alkalis, and therefore can be easily removed from the film even when concentrated dye solutions are used, if a little ammonia be added to the first wash water.

# PICTORIAL PHOTOGRAPHY: ITS DIFFICULTIES AND PLEASURES.

[Paper read before the Edinburgh Photographic Society.]

AN ancient philosopher hath put it on record that "in the multitude of counsellors there is safety." The pictorial photographer, in applying the proverb to his own case, might well give a new reading and say that "in the multitude of counsellors there is danger." For certainly he has been advised, criticised, and traduced beyond measure, despite the modesty of his pretensions. Art critics, with no knowledge of the difficulties of, or latitude of personal control available in photography pictorially pursued, have assailed him on all sides, and exhausted their vocabulary of abuse in denouncing anything photographic that dared to lay claim to pictorial merit, and, with the confidence born of inexperience, have laid it down that photography is a purely mechanical art, and that at best the photographer is but a "snapper-up of unconsidered trifles." Professors of fine art occasionally address photographers, and, while giving them a kind of qualified praise for their attempts at more artistic results in their works, generally conclude by arguing them out of the delusion that their efforts can ever be of any real artistic merit, and offering the consolatory thought that, though the higher reaches of art are beyond their skill, they may be permitted to do valuable work for the advancement of art in making memorandums for the use of painters. What the pictorial school have had to humbly accept as their due from those outside their own ranks is as nothing compared to what they have been honoured with from within. Their photographic brethren, who see nothing commendable in their work, never tire of reminding them that painters and art critics despise their productions, and curtly sum up the whole matter by giving a recipe for the production of a pictorial photograph which is generally at least commendable for its brevity, if not for its accuracy.

A writer in one of the oldest photographic journals seems to find the whole sweetness of his life in abusing the pictorial school; and his great ambition is to write the epitaph of that school, or don the mantle of Gibbon, and astonish the world with a new "Decline and Fall." Yet, withal, pictorial photography progresses apace.

Much of the adverse criticism passed on the pictorial school is the necessary sequence of any departure from traditional methods, and of what had hitherto been deemed the correct thing; on the other hand, for much of this criticism many photographers who take up the pictorial phase of photography have only themselves to thank. The fatal facility with which one photographer may imitate to a certain degree the work of another is responsible for this. If a leading worker on pictorial lines produces a striking picture, treating some new theme successfully, immediately a host of imitators arise, and, lacking in most cases the power of originality themselves, play with varying success on the same or similar themes till all are wearied with the monotonous repetition.

Another reason for much of this criticism is the want of faith on the part of photographers in the power and possibility of their own art. They seek by diverse methods to give their pictures the appearance of similarity to one or other of the monochrome methods adopted by artists. They seem delighted to be praised for a fancied or genuine resemblance to a wash drawing or mezzotint in their pictures. This weakness is finely hit off in a couplet from one of the weeklies:—

"You may fake, you may vamp up your print, as you will,  
But the trace of the camera lurks in it still."

And why should it not? Photography in some respects is unexcelled by any of the existing methods of picture-making in monochrome; particularly is this so in the rendering of tone values between light and dark. Until the possibilities of photography, as a means of picture-making, have been fully exploited, it is derogatory to the advancement of pictorial work to imitate any other method of monochrome. To do so is to practically accept as correct the limitations which critics would fain shackle upon photography. We are not daring enough in our efforts at picture-making; and, in encouragement of any attempt to venture beyond the bounds of the conventional, we may console ourselves with the thought that what is oftentimes the heresy of to-day becomes the creed of to-morrow.

Passing now to the subject proper of this paper, it seems advisable to remind our critics that there are difficulties to be surmounted in producing a pictorial photograph which are not encountered in the production of what, for want of a better term, we may call the topographical photograph; and, further, that there are powers of personal control available to the pictorial worker which give wide latitude from conception to finish of modifying and improving his pictures.

The photographer who sets out on his pilgrimage in quest of the pictorial has many a Slough of Despond to wade through ere he reaches the goal of success. Unlike the painter, whose whole training is such as to fit him for the work he is to undertake, the pictorial photographer has to begin by unlearning much that was useful to him in the earlier part of his career. All his cherished notions of what was the correct thing in definition, exposure, development, and printing, must be modified and subordinated to the idea he seeks to convey by his picture. A thorough knowledge of technique is absolutely essential, but he must not be its slave, and should rather seek to mould the powers thus given him to serve as an aid to the realisation of his aims. By under-exposure he

may obtain more contrast from a flatly lighted subject; by over-exposure he may modify harsh contrasts; in development he may modify to a great degree for the particular end in view; in printing he has the most control of all, a power which no one who has not tried what can be done in this respect can at all realise.

His knowledge of these principles of art upon which picture-making is based are, more often than otherwise, learned in a perfunctory school, and, when he sets out, say, in landscape work, to put these principles into practice, he is bewildered by the difficulties which beset his path. Unlike the painter, who may choose what he wants, and reject or modify any feature to his taste, the photographer can only select. This is often a difficult problem, and it is only by patient study of his subject, and a full knowledge of what effect the photographic plate will render, that the best effect of lighting and suggestion of the idea sought to be portrayed can be obtained. The glamour of colour often leads him astray, and it is but slowly that he learns successfully to produce in monochrome the effect desired. To get the best effect, the judicious use of isochromatic plates and a yellow screen are of invaluable service in many, if not in all, subjects. Isochromatic plates and a screen help to get over one weakness of photography, the false rendering of light and shade. It seems impossible, in some subjects, particularly where sunshine is sought to be portrayed, to adequately render this effect successfully; and, though shade can be rendered more successfully, it is rarely that we see in a photograph that luminosity of shadow which is always to be seen in nature.

The question of definition, or the amount of detail which may be rendered successfully in a pictorial photograph, is one of the greatest difficulties to contend with. According to the critics, rack the lens out of focus, and it is done. Well, it sounds easy. This is the expression of opinion of those who arrogate to themselves the monopoly of truthfully rendering things as the eye sees them. Has any human eye ever seen a picture, it matters not what it be, as the topographical photograph renders it? The eye is not an inert instrument like a lens, and in looking at any subject is never even for a second at rest, and seems, without any effort of the will, to be moving more or less across the whole field of vision. The eye never sees in nature those hard outlines of the ordinary photograph which have been too readily accepted as an inherent defect of any photographic rendering of a scene. In nature there is always atmosphere present, which softens and subdues what is harsh and inartistic in a photograph pure and simple. Let us for a moment try and recall any scene we may have visited and project on our mental vision a picture of the same, and what do we find? We cannot recall the infinite detail that must have been present, we only remember the features that impressed us. This leads to the conclusion that, even from the point of view of truthfulness, as the eye sees it, excessive detail is an error, and, from the pictorial point of view, the result should approximate to a kind of compromise between the visual and mental impressions. What these critics often forget, too, is that in many subjects treated pictorially detail is almost entirely absent, and notably in atmospheric and evening effects. There occurs to my memory at the moment as an example that fine picture, *Requiem*, by Horsley Hinton, in which detail is almost entirely absent, and to have introduced detail would have been a distinct error. This picture will be familiar to most of you, having been reproduced in the *Amateur Photographer*. Even in subjects well lighted, this absence of detail is not to necessarily mean a fuzzy picture. Softness and breadth is what is aimed at, and it is not easy to obtain such. Personally I have found this desired quality so difficult to obtain with the ordinary type of lenses that, during the past year, most of the work has been done with a set of uncorrected or spectacle lenses. The results are delightful to me, at least. With such lenses soft images are obtained without perceptible blur, just a softening of outline and nothing more. Later on I hope to show you a few results on the screen.

Pictorial landscapes in which figures play a dominant part are so full of difficulties that the average photographer, with his perfunctory training in art principles, may wisely leave them alone. On the other hand, there is a wide field for figure subjects of outdoor life and work which the photographer may attempt with more success. If the landscape be made subsidiary, and the figures the point of interest, many happy subjects may be obtained. Any attempt at posing models found among scenes of rural life and work usually results in failure. Successful effects can be had but by watching and waiting, and it requires a nicety of judgment and alertness of action to decide the right moment for exposure. If the portrayal of motion be aimed at, the difficulties are increased, for the line of demarcation between a blurred image, arrested motion, and a natural action is very narrow.

Thus have a few difficulties in the pursuit of pictorial work been commented upon, and, though the difficulties are many, the pleasures are great.

Once become imbued with the love of and desire to portray nature pictorially, and photography, to the amateur at least, rises to a higher level than that of a purposeless task or the mere pursuit of a hobby. It becomes an abiding source of pleasure, and all seasons may and can furnish us with subjects for pictures. We will, by the necessity of careful observation, be brought into closer touch with nature, and much of her

phenomena which lay unseen before will be revealed to us. Thus we may not only gratify our desire after pictorial rendering of the scenes and subjects which interest and attract us, but in our pursuit find that pictorial photography, followed out on the lines demanded by the end aimed at, may become a source of education and culture as well as an abiding pleasure.

JAMES BURNS.

### PHOTOGRAVURE.

BEFORE the Kingston-on-Thames and District Photographic Society, on January 16, Mr. Horace Wallich lectured on photogravure.

The lecturer, after explaining, with the assistance of lantern illustrations, the various methods of line and half-tone engraving upon copper plates, briefly outlined the process which was the subject of his demonstration that evening. The first step, he said, is the production of a photographic negative of the subject to be reproduced, from which a transparency is printed. From this transparency a negative image is printed on a piece of carbon tissue which is squeegeed down upon a grained copper plate, developed in hot water, and dried, forming the resist. The back and margins of the copper plate are then coated with a protective black varnish, when it is ready to be etched by immersion in baths of perchloride of iron, after which the carbon resist and varnish are removed, and the plate cleaned and polished ready for a proof. Mr. Wallich then proceeded to practically demonstrate this beautiful process, elaborate arrangements for which had been previously made by the lecturer and his assistant, Messrs. W. Drewett & Sons kindly lending a copper-plate press for pulling the prints.

The method of preparing the polished copper plate with a suitable grain was first explained, a slide being exhibited on the screen, showing, on a magnified scale, the characteristic "regular irregular" manner in which the grain is distributed over the surface. The method of obtaining this grain is comparatively simple. In a rectangular box, having a door at its base, is placed a quantity of bitumen powder. By a simple contrivance the powder can be churned up in the air within the box, after which it is allowed to rest for a little while to allow the coarse grains to settle down. The polished copper plate is now inserted in the bottom of the box for about five minutes, during which time the fine particles of bitumen dust suspended in the air gradually fall upon the surface of the plate, which, upon being removed, is heated until the grain is melted, when, upon cooling, it becomes firmly adherent to the copper. A sample plate was passed round, showing the difference between the polished and grained surface. The effect of this grain is to enable the depressions of varying depth occurring in the etched plate to retain the ink which is worked into them in printing. Each little grain protects that point of copper on which it stands from the corrosive action of the etching fluid, so that innumerable little islands are formed, thus breaking up each flat depression into a number of minute hollows, which retain the ink and hand it on to the paper in the printing press.

At this point Mr. Wallich drew the attention of his audience to the fact that, as he was endeavouring to perform in a couple of hours work which should occupy as many days, it was obviously impossible to demonstrate the actual photographing of the picture and the printing of the transparency and carbon negative, but would proceed to squeegee and develop upon the copper plate a previously exposed carbon negative or resist. The tissue used for this purpose is similar to that used in the well-known carbon process, excepting that it is prepared with pigment of a special colour. Development was conducted in the manner common to the carbon process, with the result that a delicate copy of the original negative in relief remained firmly adherent to the grained copper plate. After drying the resist, black varnish is applied to the portions it is desired to protect from the action of the perchloride of iron, and the etching proceeded with. In order that this interesting operation might be the better followed by the spectators, the gas was extinguished, and the light from a limelight lantern concentrated upon the dish. On immersion in the etching fluid, the copper, being unequally protected by the relief resist, is first attacked in those parts where the gelatine is thinnest, forming the deep shadows. Then follow the thicker parts, forming the middle tones, the corrosive action of the solution finally finding its way through the thickest portions of the film, forming the lightest tones, but these are scarcely bitten at all, as the action is at this point interrupted by withdrawal from the solution and washing in cold water. The process occupied eighteen minutes, during which time the methods of preparing and testing the several baths of perchloride of iron by means of an hydrometer were fully explained. The carbon resist and protective varnish were next removed by means of benzole, and, after a thorough cleaning and polishing with precipitated chalk, the plate was handed over by Mr. Wallich to his able lieutenant, Mr. Mulliss, who performed the operation of inking up and pulling a proof on India tint paper in the press.

The plate was laid upon a hot plate, the ink worked all over and into the hollows with a "dabber" of leather by a peculiar rocking motion, the superfluous ink wiped off with coarse canvas, finishing with the palm of the hand, and the margins polished so as to print white. The amount of care that is required at this stage may be understood when it is stated that it takes from a few minutes to half an hour (according to the size of the plate) to do the inking, polishing, and putting through the press of

each copy. It is not quite like running off the copies of a daily paper. It was explained that, after the etching was done, and an "etch proof" pulled, the plate could usually be much improved in the hands of a skilled engraver, some of the engraving tools used being shown. To enable the plate to yield a large edition, its surface is protected by hard electro deposit of iron, technically known as steel facing. As soon as this iron coating showed signs of wear, it could be chemically removed without injuring the copper, and "refaced."

The proof was handed round for inspection, and excited the admiration of all present. An impression was also taken from a retouched plate of the same subject to illustrate the improvement that can be effected by some judicious work on the copper after the plate has been etched.

### THE AFFILIATION OF PHOTOGRAPHIC SOCIETIES.

THE Annual General Meeting of Delegates was held at 12, Hanover-square, London, W., on Friday, January 20, 1899, Mr. W. Thomas (Chairman) presiding.

The Chairman's report for the past year and the Treasurer's balance-sheet were read. The report with certain amendments and the balance-sheet as read were formally adopted, on the proposition of Dr. Baldwin (Rotherham), seconded by Mr. H. Snowden Ward, R.P.S.

The election of officers for the ensuing year was next proceeded with. The appointment of a Chairman in succession to Mr. Thomas (resigned) was eventually deferred until the next meeting. It was agreed that Mr. George Scamell be asked to serve again as the Treasurer of the funds, and Messrs. R. Beckett and A. Mackie were appointed the Auditors of accounts. The services of Colonel Waterhouse, as Honorary Secretary, a matter dealt with in the report, were accepted with acclamation.

It was proposed and seconded that a vote of thanks to the Treasurer and Auditors be recorded, and the same was carried unanimously.

Mr. Mackie, R.P.S., proposed that the thanks of the Committee be conveyed to the Judges of the various competition prints sent in during the past year for adjudication. Mr. Churchill (Woolwich) seconded the motion, which was carried *nem. con.*

It was agreed that a Committee be appointed to co-operate with the Sub-committee of the Council appointed to consider the relations between the two organizations. The following were appointed a Committee for the purpose: R. Beckett (Hackney), J. A. Hodges (Chiswick), E. Dockree (Brixton), J. C. S. Mummery (North Middlesex), C. H. Oakden (South London), A. F. Taylor (Ealing), and the Chairman.

It was arranged that steps be taken to revive the old lectures as occasion offered, and to replace the damaged and broken slides.

The question of the Yorkshire Exhibition was then raised, and, after some discussion, Dr. Baldwin (Rotherham) said he was at the Leeds meeting, when it was arranged that an Exhibition should take place under the auspices of the Yorkshire affiliated societies. How far its carrying out had adhered to this intention he did not wish to say, but the Rotherham Photographic Society, he wished it to be noted, had all its pictures refused. He could not believe that the work was so utterly bad, and he felt that Rotherham had just cause for complaint. As regards the proposed federation in Yorkshire, he was sure Rotherham and South Yorkshire would not join, and, in coming up to this meeting, he thought there should be some expression from the Committee on the conduct of the Exhibition. However, having raised the point, he should be satisfied if Yorkshire were left to fight it out in Yorkshire, and was confident of the result.

Further discussion ensued, and the Chairman traced the history of the movement from its inception at the Leeds meeting of delegates and secretaries through successive stages to the present time.

The correspondence that had passed between the Chairman, the Secretary, and the authorities of the Exhibition in Bradford, covering the whole ground so far as the facts in the possession of the Affiliation were concerned, was then read, from which it clearly appeared that any misunderstandings which had arisen had been entirely cleared away, to the satisfaction of the Yorkshire Committee at the time. Personally, the Chairman would welcome an opportunity of laying the whole matter open to the world, by the publication of this correspondence. It was an agreeable surprise to him, after what he had read and heard, to find, on carefully going through every letter and communication, that there appeared not one single word which he would wish unwritten.

A proposition from the Woodford Photographic Society was read, urging that meetings take place on definite dates to be determined. It was recognised, however, in the discussion that followed, that such an arrangement, which had been tried before, was inconvenient very often for the business to be done, and that the present system was preferable.

The Chairman called attention to the present of a clock which was to be handed to Mr. Child Bayley that evening, and said he had received a telegram from Mr. Bayley, regretting his inability to attend owing to a prior engagement. The Chairman said the Committee was anxious in some way to show its appreciation of his labours as the Secretary, labours which terminated with the close of last year, and it was thought that the Affiliation could best carry this intention into effect, not by individual appeals to the delegates, but as a body by voting as much as reasonably could be spared from the limited funds at their disposal.

He wished to record and express his deep obligations to Mr. Bayley for his many services, in which he knew the Committee desired to join, and he desired that the small, but he hoped sufficiently substantial, offering the Committee was making should be conveyed to him, with the best thanks, kind regards, and hearty good wishes of the Affiliation for him in whatever sphere of life he had to work.

Mr. R. Beckett felt it incumbent upon him to propose in a few words the hearty vote of thanks of this Committee to Mr. Thomas for his services as Chairman, and for the zeal and energy with which he has approached everything touching the welfare of the scheme. He was exceedingly sorry that what he hoped were only rumours had been confirmed, and that Mr. Thomas was withdrawing from their midst. He trusted that rest and change would quickly restore him to health and activity.

Mr. Fry had great pleasure, as one of the newest delegates, in seconding the motion of one of the oldest amongst them, and the vote was carried unanimously, Mr. Thomas briefly replying, and returning thanks for the valuable help which he had always received from the Committee and its individual members.

### "GRAVURA."

An ordinary meeting of the Eastbourne Photographic Society was held on Tuesday, January 17, Mr. Phillips in the chair. The business of the evening, and its chief feature, was the introduction of a new paper for printing by development. Mr. A. C. Baldwin, the representative of the Paget Prize Plate Company, attended, and said that it was about to be placed on the market under the name of "Gravura." The demonstrator briefly reviewed the various kinds of photographic printing papers which were at present used, under the names of carbon, platinotype, bromide, and the newer so-called P.O.P. He said that the course of time seemed to demand that makers of paper should always be looking out for some more or less imaginary photographic "philosopher's stone," in the shape of a paper which, by certain modifications in the treatment, would give anything and everything which the user might desire; and, although they had not perhaps reached that ideal, yet he claimed that in "Gravura" they had a paper which gave in the finished result a very wide range of colour. It was possible, by means of modification of the exposure and corresponding development, to get a rich black or a fine Bartolozzi red, with shades of brown between, simply by alteration of exposure and dilution of a standard developer. Another advantage was that the sensitiveness of the paper was so adjusted that it might be developed by ordinary gas or candle light.

In practice, magnesium ribbon was a convenient illuminant for printing purposes, from 2-inch to 4 inches burned at various distances from 1 foot to 4 feet according to colour required. Mr. Baldwin said that, though everything obtainable from a maker of repute was of good quality, yet his Company claimed in this case to have "gone one better," and met the proverbial "long-felt want" in offering to the photographic world a paper such as he described.

Its practical manipulation was then shown by exposing it under various negatives and varying conditions, producing all the colours mentioned, the reds and browns being especially clear and brilliant.

Several other dried and finished prints had been brought, and were handed to the members present for inspection.

The lecture was listened to with marked attention, none the less, perhaps, because it was delivered in a genial and conversational fashion. At its close Mr. Plomer proposed and Mr. Holloway seconded a well-deserved vote of thanks.

### DEVELOPMENT OF PRINTING-OUT PAPER.

Before the London and Provincial Photographic Association, on January 19, Mr. E. H. Bayston in the chair, Mr. T. E. H. Bullen discoursed on "The Development of Printing-out Paper." He said that he had been primarily induced to take up this particular branch of photographic printing by the fact that urgency had required the completion of certain prints in a time which was insufficient if they were to be done by print-out methods. It was desirable that they should be of the character understood as "photographic" by the general public, that is to say, bromide paper, or other similar development process, pure and simple, would not do, so he was compelled to adopt some other expedient, and that was the development of partially printed P.O.P. prints. The experiments were conducted with papers of all brands, and one thing was noticed, that it was infinitely the better course to buy direct from the factory than from the retail dealers. Staleness seemed to show itself much more when development was resorted to than in the case of printing out, and, whereas excellent results followed the course he advocated, they were indifferent with papers of any degree of staleness. He observed that there was a tendency to strive for the photographic blue tone by direct development, but he was convinced that it was just as impossible to get this tone without the aid of gold by printing out altogether as it was by a development process. Gold was essential for such a tone. Development gave exceedingly good tones, but the photographic blue produced by gold was beyond reach without the aid of gold. Published formulae all seemed to strive for the shortest possible ex-

posure of the paper that would produce a result, but in his own opinion it was necessary to have not only a visible image, but one certainly not less than a quarter or a fifth printed. This would mean that five times the number of prints otherwise possible could be produced in an equal time, which was an excellent power to have. As regards evenness of tone, the rule that holds when printing out, say, a dozen cabinets, namely, to print to the same depth, applies also in development, at any rate from a commercial point of view. Exactly the depth required must be regulated by the same rules which decide the exposure of the plate in the camera, but, above all, expose enough.

Under-exposure yields, by development, a sepia tone, which does not lend itself to after-treatment for the usual photographic tone, but correct exposure gives a red print, which is amenable to subsequent toning processes. Mr. Drinkwater finds that of thirty formulae only three are of practical value. Mr. Bullen thought Mr. Drinkwater himself was to blame for this by the shortness of his exposures and the strength of the developer he advocated. The exposure should be so great that the finished tone of the print, with a weak developer, was red. There was no difficulty in vignetting portraits by the development process, as had been inferred. In looking at the prints during exposure, of course care must be taken to shade the frame, because very little light is wanted to destroy the purity of the whites when development is resorted to.

Cleanliness of hands and utensils is still more important than for printing-out processes, the slightest thing being sufficient to mar the result. The toning of the prints may be done either by combined or separate baths; but, for practical purposes, he preferred the combined baths. As regards the statement that gallic acid, upon which Mr. Bullen's experiments were based, gave green tones, it was a question of exposure and judicious development. Mr. Bullen showed twelve prints of different tints, which were to show the effect of varying the concentration of the developer, and beyond the third there was not the slightest trace of green. All those after the fifth were open to toning to any colour, according to the bath used. Dense negatives are negotiated by the dilution of the developer, and thin negatives by using a stronger solution. The developer referred to is the Gem Meteor P.O.P. developer, and the results, which were shown by Mr. Bullen and Mr. Mayall, were such as spoke very highly of its qualities.

### ON THE PRODUCTION OF WARM TONES ON BROMIDE PAPER.

[Paper read before the West London Photographic Society, January 20, 1899.]

To the amateur, whose hours of daylight are mostly monopolised by work other than photographic, the bromide process is indispensable, and, now that such a large choice as regards surface, texture, and tint of paper is available, bromide printing and enlarging claim and receive the attention of all classes of photographers, from the beginner to the serious picture-maker and exhibitor.

I have always felt, as have hundreds of others, that the only drawback to the process was that its results were in black and white, and only in black and white. The introduction of the hot alum and hypo toning method by the Eastman Company some years ago was a great step in advance, and it emphatically holds the field as the simplest and easiest means of procuring tones ranging from a light sepia to a brownish-purple.

In some quarters the permanence of this process has been questioned; but, whether considered from the standpoint of practical experience or from a purely theoretical point of view, such doubts are quite unfounded. Numberless prints toned in this bath are in existence, and I have not as yet seen one which has undergone the slightest change. The print, in the first place, must be developed up dark, ensuring an image with the maximum of silver deposit, which, in itself, makes for permanence, and in the toning bath this deposit is converted almost, if not entirely, into one of silver sulphide, which is, undoubtedly, the most stable of all the silver salts. Furthermore, some rough experiments I have made lead me to believe that the toned image resists the action of certain destructive agents better than does the original image of metallic silver. Comparisons are made between this process and the sulphuration of gelatin-chloride and albumen prints, but such comparisons rarely go beyond the cry of "sulphur toning." In the case of bromide prints toned in the hypo-alum bath we have a chemical reaction, in which a comparatively permanent image of metallic silver is changed into an image of sulphide of silver of equally great, or possibly greater, stability. In the case of the chloride print we have totally different conditions.

We have a complex reaction between sulphur and a feeble image of various organic salts of silver, which in themselves, without any sulphuration, are generally of a somewhat fleeting character. Setting aside the indefinite organic constitution of the modern chloride image, its lack of depth is its principal weakness, as shown by the much greater permanence of old silver prints which were made in the days when paper was much more heavily salted and silvered than now, and when negatives of much greater contrast were employed.

The toning bath and the method of using it is as follows:—

Hypo.....	10 ounces.
Alum.....	1 ounce.
Water.....	70 ounces.

The hypo is first dissolved, the alum then slowly added, and the solution raised to the boiling point. A new bath frequently acts very slowly and unduly bleaches the prints, and it must therefore be ripened, which is best done by leaving a number of waste prints to soak in it for about a day. The bath must not be filtered, and the best working solution consists of equal parts of old and new bath. The prints may be developed by any developer, although metol is best, and they must be of 'somewhat greater density than usual, as they undergo a slight bleaching in the process of toning; and, in addition to this, the brown image which results is, of course, less opaque than one in black. The action will usually be completed in from fifteen to thirty minutes. The solution is kept at a temperature of from 110° to 120° F. during the process of toning. The prints must, of course, be thoroughly fixed in the first instance, and it is advisable to give them an alum bath before toning. It is best to immerse them in the solution when it is cold, and then raise it gradually to the above temperature, which must not be exceeded, else blisters will probably arise. It has been recommended to transfer the prints from the toning bath to a warm bath of alum, but I prefer to use the alum bath first, and to allow the prints to cool between the toning and final washing operations. Some deposit will probably be found adhering to the surface of the prints, which is removed by sponging with cotton wool, and they should then be well washed.

This bath may also be employed cold, in which case the toning action may take from four to twelve hours for its completion, the time depending upon the condition of the bath. Some method must be adopted to keep the prints separated from each other and entirely submerged. For instance, they may be attached to glass plates by indiarubber bands and supported in a grooved tank, or they may be suspended from corks.

Another method of producing similar tones is to employ a bath of—

Ammonium sulphide (fresh) .....	1 ounce.
Water .....	20 ounces.

This is a slow process, and, on account of the somewhat robust smell evolved, it is best to allow it to work its own sweet will in the back garden. If this process is adopted, it is evident that the fixing and washing must be very thorough, and a final wash will complete the operation.

J. BROWN.

(To be continued.)

#### HARRISON'S PRINTING FRAME FOR PROCESS WORK.

MR. HARRISON employs hollow chambers or pads, *d* (fig. 1), of indiarubber surrounded with cloth, canvas, wood, metal, or other suitable material, adapted to withstand the pressure of air or gas introduced and contained within the chambers or pads, *d*, as heretofore mentioned. The said hollow chambers or pads are secured to the lid of printing frame, *x*, or machines, say, with a suitable cement or other efficient means, and is inflated with air or gas under pressure.

He may use, for the purpose of inflating, any ordinary forcing pump

or like device, the air or gas under pressure being introduced to the interior of the hollow chamber or pad, *d*, through a small duct formed in any part of the chamber or pad, as may be found most suitable, and provided with inflating and deflating valves, *x* and *z* (fig. 2).

He further employs indiarubber strip, felt, or any other suitable material, on the rabbet, *b, b*, (fig. 1), which projects on the inside of printing frame, *a* (fig. 1); said indiarubber strip or felt is secured to the rabbet with a suitable cement or other efficient means.

When the rubber strip is fixed to the aforesaid rabbet, a resisting plate of glass, *c* (fig. 1), is laid on the rabbet, *b, b*, and on the plate glass, *c*, a negative, *i*; on the negative, sensitised paper or metal plates, *j, j* (fig. 1).

The hollow chambers or pads are secured to the lid, *x* (fig. 1), and on the lid are fixed battons, *x, x*, and *x, x* (figs. 1 and 3), the ends of battons project one inch or more over the sides of lid, *x*, and chamber, *d*; the lid and chamber are then fitted into the printing frame, *a, a*, and the battons resting on the printing frame, *a, a*, as heretofore mentioned.

Secured in the sides of said printing frame, *a, a*, are two hooked hinged lock bolts, *n, n* (figs. 1 and 3), which are turned upwards over the ends of battons; pressure is then applied.

## Our Editorial Table.

### GRIFFIN'S ACID HYPO FIXING CARTRIDGES.

Manufactured by John J. Griffin & Sons, 20-26, Sardinia-street, Lincoln's Inn-fields, W.C.

AN acid fixing bath is recommended for Velox prints, and Messrs. Griffin here supply the materials for compounding such a bath, consisting of a mixture of alum and hypo in powder and an acid solution in a small vial. Sufficient of the salts are supplied for sixpence to make twenty ounces of solution. The following are the instructions for use, it being noted that the bath is also recommended for bromide papers, dry plates and films:—Dissolve the contents of the box in one pint of ordinary water, then pour into this solution the contents of the small vial, which will be found imbedded in the powder, and the acid hypo fixing bath is ready. This bath keeps for a very long time, especially in well-stoppered bottles. It can be used repeatedly until exhausted. A sure sign of exhaustion of the bath is that the prints or dry plates fixed in it will have a sweetish taste, even after half an hour's washing in water. Furthermore, fixing will become very slow, and prints fixed in an exhausted bath will promptly turn yellow or brown in the whites when exposed to the light after they leave the fixing bath. Keep the prints or dry plates moving in the fixing bath, in order to ensure rapid and uniform fixing.

### PRACTICAL PICTORIAL PHOTOGRAPHY.—PART II.

By A. HORSLEY HINTON. London: Hazell, Watson, & Viney, 1, Creed-lane.

IN the second part of his little work on *Practical Pictorial Photography* the author devotes himself to a development of the theories enunciated in Part I., which was issued last autumn. Perhaps the best way of conveying to the reader an idea of the scope and intention of the present volume is to assign to it the character of an essay on the construction of pictorial photographs. Mr. Hinton, with all the engaging ingenuousness of the professor of leger-de-main, shows you a beautiful trick photograph, and then most conscientiously tells you how it is produced. You take a foreground and a sky, and fit the one to the other. You put in a light here and a shadow there. You block out in one place, "subdue" in another; so on, so on, and hey, presto! there is your pictorial photograph. This being in brief how it is done, can you wonder that Mr. Hinton is finding followers and imitators by the score? The shop boy or mill hand, after digesting a couple of dozen pages of Mr. Hinton's instructions in the manufacture of pictorial photographs, thinks himself as good as his master, and, to judge by what we see on the walls of the exhibitions, very often is. But we mean no offence when we say that one Hinton is quite enough. We can recommend the little book before us to all those who want to study the grammar of Mr. Hinton's characteristic style of photography, and we hope that it will make many of its readers think for themselves, and not become mere slavish imitators of its accomplished author's style of work. By the way, "pictorial photography" is not all landscape work. Is there no such thing as pictorial portraiture?

### A MANUAL OF PHOTOGRAPHY.

By A. BROTHERS, F.R.A.S.

Published by Charles Griffin & Sons, Limited, Exeter-street, Strand.

THIS is the second edition of a work which was originally published in 1892, and the author has seized the opportunity of making some important additions to it, notably as regards colour photography, radiography, and other subjects which have come into prominence during recent years. The book extends to many hundreds of pages, and in wealth of illustrative examples of phototypic reproduction processes is not surpassed by any similar work with which we are acquainted. Indeed, simply regarded as a book for the library, Mr. Brothers and the publishers are to be congratulated on issuing a very handsome and well-printed volume. But it has the far more valuable recommendation of showing on every page the work of a competent hand. Mr. Brothers' practical acquaintance with photography commenced, if we are not mistaken, some forty odd years ago, and has continued ever since, and he is thus perfectly qualified and equipped for his task. He takes the reader practically over the whole ground of his subject, and the result is a

highly informative book, which, if it suffers here and there from the necessities of compression, yet does not leave one in ignorance of any of the numerous essentials of his theme. The historical notes are especially valuable, and the illustrations are instructive, diverse, and well-executed. We can cordially recommend the volume as a worthy addition to any library. It is published at One Guinea.

#### A TREATISE ON PHOTOGRAPHIC OPTICS.

By R. S. COLE, M.A. London: Sampson Low & Co., St. Dunstan's House, Fetter-lane, E.C. Price 6s., 328 pp.

When a second edition of Mr. Cole's admirable work is called for, he will be well advised to subject the passages relating to colour photography, pinhole work, sensitometry, and some other minor sections of the book to careful revision at the hands of somebody having the advantage of a closer acquaintance with those subjects than he appears to possess. The errors into which he has fallen do not, however, call for detailed reference, inasmuch as they fail to intrude themselves into the real scope of the book. The author enters exhaustively into the optics of the photographic lens, and to that class which is qualified to follow him in the formulae and calculations with which his pages bristle this treatise will be simply invaluable. It is the only English book extant that treats in theory of photographic optics, and therefore, as a source of reference for the benefit of those who esteem a photographic objective as a mathematically calculable production, Mr. Cole's able and exhaustive treatise at once steps into a place that has long been vacant.

The book has been compiled for the information of those photographers whom the author assumes to entertain a desire to know the theoretical principles employed in lens construction, but this is a class whose smallness we fear would astonish Mr. Cole. Notwithstanding the dilution of his mathematics, the book appeals rather more to the lens-maker than it does to the lens-user. The late Mr. Traill Taylor, in his handy little book on *The Optics of Photography and Photographic Lenses*, dealt with his subject in a manner that is understood by practical photographers, and shrewdly eschewed formulae and calculations, and the consequence is, that as far as it goes his book has proved highly informative and useful to many a photographer. Monckhoven's *Optics*, too, translated and published thirty-three years ago, may in parts be read with profit and instruction to this day because, like Taylor, the author subordinated theory to practice.

There is still room for a book about lenses, on the lines followed by Monckhoven & Taylor; for it must not be overlooked that in the last thirteen years the wide variety of glasses of differing refractive and dispersive indices placed at the disposal of the optician has resulted in the production of photographic lenses having properties at one time regarded as unattainable. Those properties, as they manifest themselves in practical application, are by no means perfectly understood or appreciated by the users of "new" lenses as they are conveniently termed, so that there still remains an unbeaten track for a competent writer to traverse.

But this digression must not be understood as in any way meant to depreciate the value of Mr. Cole's book, which in its amplitude of detail and prodigality of illustration at once takes rank as a standard work of reference.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, February 1. Chat on Elementary Optics, by Rev. F. C. Lambert.

MR. J. CHROSDALE COULTAS, of Chapel-lane, Headingley, is the new Hon. Secretary of the Leeds Photographic Society, which now meets in rooms at the Philosophical Hall.

McKELLEN, LIMITED.—We understand that the shares offered to the public by Messrs. McKellen, Limited, have been very well subscribed for, and an allotment was made on Tuesday last.

FIRE.—Shortly after nine o'clock on the night of the 20th inst., a fire was found to have broken out in the photographic studio of Mr. Edward Lewis, Les Eaux, Clytha Park, Newport, Mon. The building was entirely destroyed.

The photographic dealing and picture-framing business previously carried on by Messrs. Bidwell & Co., at 36, Midland-road, Bedford, will now be carried on by Bidwell & Brown, to whom all communications, &c., should be addressed.

EASTMAN PHOTOGRAPHIC COMPANY, LIMITED.—The dividend warrants have been posted by the Eastman Photographic Materials Company, Limited, for ten per cent. on both the ordinary and preference shares, making, with the interim dividend already paid, a total dividend at the rate of twenty per cent. per annum for the year ending December 31, 1898.

THE AMER'S ANTIPATHY TO PHOTOGRAPHY.—Miss Lillian Hamilton, M.D., who for three years was physician to the Ameer at Cabul, told an audience the other day that Abdul Rahman has a great antipathy to photography. On one occasion he asked his lady doctor if she could reconcile the possession of her camera with the Scriptural injunction to make to herself neither graven image nor the likeness of anything in heaven or on earth. Miss Hamilton did not say what her answer to this poser was. We wonder if it was "negative."

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION. On Thursday, February 9, at the White Swan, Tudor-street, instead of the members meeting to discuss photographic matters there will be a supper, and Mr. Haddon will take the chair at 7.30 sharp. The Hon. Secretary hopes that a good number of members and friends will meet that evening.

CRIPPLEGATE PHOTOGRAPHIC SOCIETY.—This Society has recently been formed, with its headquarters at the Cripplegate Institute. The annual subscription is 5s., with use of dark room two nights weekly. There is no entrance fee. All those desirous of becoming members are invited to communicate with the Hon. Secretary, Mr. Alfred T. Ward, Cripplegate Institute, Golden-lane, E.C., of whom further particulars can be obtained.

THE Third Annual Dinner of the South London Photographic Society was held at the Montpelier Hotel, Peckham, on Saturday, January 21, when the President (Mr. C. H. Oakden, F.R.P.S.) was supported by about fifty members and visitors. Mr. Child Bayley gave the toast of the Society, which he congratulated on having reached a total membership of 200. The other toasts included "The Press," "The Visitors," and "The Chairman." After the speeches, which were brief, the evening was devoted to an enjoyable smoking concert.

THE CRIPPLEGATE INSTITUTE.—The Governors of this institution, which is situated in Golden-lane, E.C., include among their winter classes one for photography (for men only), which is conducted by Mr. C. W. Coe, of Messrs. M. G. Wood's. A course of seven practical lessons is given in development, printing, and toning, specially arranged for amateurs. All materials and apparatus are supplied free. The fee is 7s. 6d. per course, with no extras. The syllabus is: No. 1, Apparatus and lenses; No. 2, Plates and exposures; No. 3, Development; No. 4, Development (lessons in); No. 5, Printing; No. 6, Toning; No. 7, Negatives, their defects and remedies. The classes are held at seven p.m. on every Friday. Particulars can be obtained at the Institute.

PHOTOGRAPHIC CLUB.—The annual Ladies' Lantern and Musical Entertainment, which took place on Wednesday, January 18, under the direction of Mr. E. A. Newell, was conducted throughout in a highly creditable manner. Mr. F. A. Bridge occupied the chair, and the programme offered an admirable selection of talent, the artistes being Madame Alice Lovenez (soprano), Miss Florence Venning (contralto), Mr. Robert Dennant (baritone), Mr. W. R. Maxwell (tenor), the humourist Mr. Fred Stephens, the shadowgraph genius Mr. Frank Kennard, and Mr. R. B. Hopkins, who energetically wielded the silver bells, Mr. T. F. Noakes accompanying. At intervals lantern slides of a miscellaneous character were thrown upon the screen, and until a late hour the concert-room was crammed with a large and appreciative gathering. The result can only be gratifying to the Club, and especially to Mr. Newell, who had devoted himself very earnestly to the organization and carrying through of this the last, and probably most successful, concert yet given by the Club.

THE CHORUS LADY AND HER PHOTOGRAPHS.—An interesting case relating to the value of photographs came on for hearing, a few days ago, at the Bootle Police Court, when Mr. Vereker, of the *Aladdin* Pantomime, Royal Lancaster Theatre, Bootle, was summoned by Miss Mabel Esmond Cahill, actress and authoress, for unlawfully detaining six photographs, the property of complainant. Mr. Wall, who appeared for the complainant, stated that the photographs represented his client posing in various attitudes, which, when hung outside the theatre in which she was appearing, were calculated to advertise her. The photographs had been delivered to the defendant's agents, and, when they were applied to for them, the complainant could not get them. She was referred from one person to another, and, thinking she was being humbugged, she took out the present summons. The defendant said the complainant was for a time in his employ. He had never asked her for the photographs, as she was only appearing as a chorus lady. It was usual to display the photographs of the leading ladies only. He did not know that the photographs were in the theatre until he received the summons to deliver them up to complainant. As far as he knew, the complainant had never asked for the return of the photographs. The photographs were then produced in Court, and the defendant said it was the first time he had ever seen them. The photographs were then handed to the complainant, and the defendant was ordered to pay the costs.

RE GEORGE ALFRED WOODFIELD, formerly photographer of Week-street, Maidstone.—The public examination of the above-named debtor took place before Mr. Registrar Warner, at the Maidstone Bankruptcy Court on the 18th inst. Replying to questions, the debtor stated that he commenced business as a photographer at 38, Week-street, Maidstone, and subsequently, about five years ago, he removed to larger premises at 105, in the same street. His rent at the former place was 15*l.* per annum, and at the latter place 60*l.* per annum, in addition to rates and taxes. During the epidemic in Maidstone his trade fell off considerably, as the bulk of his customers lived in the country districts, and during the epidemic they kept clear of Maidstone. His wife claimed some of the furniture. He admitted that he had over-estimated the value of his effects, because he valued them as a going concern, instead of what they would fetch under the hammer. He valued his apparatus, &c., at 136*l.*, but his studio, which was worth 40*l.*, went for 4*l.* 6*s.*, and a background that cost him 9*l.* or 10*l.* went for 17*s.* Every creditor would have received 20*s.* in the pound, or 15*s.* in the pound at least, if his landlord had agreed to accept a tenant that witness found. This gentleman would have purchased the business as a going concern, and he would have paid 65*l.* per annum rent, but the landlord asked 85*l.* Afterwards the landlord agreed to accept 75*l.* per annum, but the customer would not pay more than 65*l.* Witness was asking 200*l.* for the business, and he was sure that he could have got 150*l.* for it. That happened about a week before the petition in bankruptcy was filed. The landlord had not yet relet, and the premises were at present empty. He had kept a cash book, but no day book or ledger. He first discovered that he was not progressing satisfactorily about two years ago. In fact, as long ago as 1896, he had a small deficiency. His household expenses had amounted to about 30*s.* per week. His large creditor had been very kind to him, and had assisted him in every way. The examination was ordered to be closed.

## Patent News.

THE following applications for Patents were made between January 9 and January 14, 1899:—

- ANIMATED PHOTOGRAPHY.**—No. 486. "Improvements in Apparatus for Taking and Projecting Animated and other Photographs." R. W. PAUL.
- LANTERN SCREENS.**—No. 481. "Improvements in or relating to Lantern Screens." T. SWINGLER, JUN., and R. HINMAN.
- ARTIFICIAL-LIGHT PHOTOGRAPHY.**—No. 601. "Improved Means for Facilitating the Taking of Photographs by Artificial Light." C. BERNHOEFT.
- ROLLABLE FILMS.**—No. 620. "Improvements in Sensitised Continuous Films for Photographic and Cinematographic Purposes." J. T. SANDELL.
- STEREOSCOPIC CAMERAS.**—No. 675. "Improvements in Stereoscopic Cameras." A. L. GRIMSHAW.
- DARK SLIDES.**—No. 783. "Improvements in or connected with Photographic Dark Slides." J. W. DEBENHAM.
- WASHERS.**—No. 808. "Washer for Photographic or other Prints, Plates, or Films." B. L. HURST and J. McCLURE.
- PHOTOGRAPHIC PROCESSES.**—No. 887. "Improvements in Photography and in Materials and Processes connected therewith." J. E. THORNTON and C. F. S. ROTHWELL.
- CAMERAS.**—No. 895. "Improvements in and relating to Photographic Cameras." G. WISHART and F. MACKENZIE.
- HALF-TONE SCREENS.**—No. 915. "Improvements in Screens or Gratings for the Half-tone Photo-mechanical Engraving Process." H. LYON.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

January.	Name of Society.	Subject.
30.....	Bradford Photo. Society .....	Members' Slides. Criticised by P. E. Newstead.
30.....	Camera Club .....	Photo G. carings. R. Dookree.
30.....	Kingston-on-Thames .....	Subject Competition.—Exhibition of Slides lent by the Royal Photographic Society.
30.....	Richmond .....	Composition and Selection of Subjects in Pictorial Photography. A. Horsley Hinton.
30, 31 .....	Southsea .....	Annual Exhibition.
31.....	Birmingham Photo. Society ..	Fourth Annual Conversazione.
31.....	Hackney .....	Hand Cameras. Jno. H. Gear.
February.		
1.....	Brentford .....	Printing, &c., P.O.P. Mr. Read.—Bro-mide. Platinotype. Messrs. Abbott and Pearce.
1.....	Croydon Camera Club .....	Council Meeting.
1.....	Leeds Camera Club.....	Gum-bichromate Process. W. J. Warren.
1.....	Photographic Club .....	Chat on Elementary Optics. Rev. F. C. Lambert.
1.....	Southsea .....	Annual General Meeting.
1.....	Woodford .....	Exposure and Development. R. Ohild Byley.
2.....	Bolton Mutual Photo. Society ..	Lecture: Amateur Photography.
2.....	Leeds Photo. Society .....	Colour and its Reproduction by Photography. E. J. Wall.
2.....	Leigh .....	Lecture: Practical Points in Exposure, Development, and Printing.
2.....	Liverpool Amateur.....	Demonstration: Enlarging and Exhibition of 1/125 Slides. William Harvey.
2.....	London and Provincial .....	Photographic Society Life. Walter D. Weir.
3.....	Croydon Microscopical .....	Conversational Meeting.
3.....	West London.....	On Hand Cameras. W. Taylor.

### ROYAL PHOTOGRAPHIC SOCIETY.

JANUARY 24,—Technical Meeting,—Mr. A. Haddon in the chair.

#### DEVELOPMENT OF GELATINO-CHLORIDE PAPER.

Mr. J. STERRY read a paper on "The Development of Gelatino-chloride Papers, and the Control of the Colour of Resulting Prints," the main object of which was the consideration of the question of the production of prints by development alone without subsequent toning. As far back as 1883 it was shown by Mr. A. Cowan that a very great variety of tone could be obtained in the development of chloride plates, and, if the same could be produced on paper choice could be made to suit the subject in hand, but in this case the difficulties were far greater. In 1892, Herr Valenta described a series of experiments in which, by means of development alone, he obtained sepias, browns, and purples, giving the following as a satisfactory formula: Pyrogallie acid,  $\frac{1}{2}$  per cent.; citric acid, 1 per cent.; sodium sulphite, 2½ per cent. The method appeared to have received some attention at the time, but to have been afterwards almost forgotten. This was followed by Dr. Liesegang, who used a saturated solution of tannin and obtained a red-brown print, but twenty minutes were required for development, and in 1893 Mr. Warnerke and Mr. H. Smith made further contributions to the subject, which then dropped until 1897, when Dr. Liesegang gave the result of a large number of experiments with various developers used

in very dilute neutral or acid solutions, from which he arrived at the conclusion that for practical purposes only gallic acid, hydroquinone, pyrogallol, par-amidophenol, and metol were of importance, the others failing because the paper was so easily stained (THE BRITISH JOURNAL OF PHOTOGRAPHY, 1897, p. 359). Last year, working upon similar lines (*idem*, 1898, p. 714), Mr. W. E. A. Drinkwater found that, with the addition of small quantities of bichromate of potash to a very dilute solution of pyrogallie acid, there was a marked increase in the rapidity of development, and that with suitable proportions a very satisfactory brown colour could be secured, the printing being carried just far enough to show the principal detail clearly. Experimenting with this method, Mr. Sterry at once found it satisfactory, both for colour and rapidity. The amount of bichromate required in the developer was stated roughly at from 1 part in 50,000 to 1 part in 600,000, excess beyond that necessary to develop a print fully in from 1½ to 2 minutes, always leading to a total change in the colour, and also to general fog. A definite quantity of developer, about 2 ounces to a quarter-plate, must be used, or the free silver present would materially affect the print; chromic acid answered as well as bichromate. When a print has been printed right out and fixed, there is a faint image on the paper support after removing the gelatine; but the small amount of exposure necessary for development does not show upon the paper at all, although after development there is a distinct image upon the support. Whilst Mr. Drinkwater's method was largely dependent upon physical development, it was not altogether so, for development could be carried out after washing the print, and, as a preliminary bath for removing all traces of free silver from the print, decomposing any combination of gelatine and silver, and removing fog, the following chemicals proved effective: hydrochloric, hydrobromic, and hydriodic acids, hydrogen peroxide, potassium permanganate, and chromic acid. The lecturer had adopted hydrochloric acid as being the simplest and most suitable for chloride papers, immersing the exposed and washed paper in a two per cent. solution for about a minute after which the print could be developed with almost any developer, although a restrainer was generally necessary to keep back all trace of fog. The colours obtained were most varied, depending upon the exposure, the retarding solution, and the developer; as with chloride plates, short exposures and strong developers gave cold colours, longer exposures and well-restrained developers giving warm tones. Of the two methods brought forward, Mr. Drinkwater's was by far the easier to work, but was practically confined to one or two shades of brown. The principal difficulties in the way of development of gelatino-chloride paper, so as to obtain a variety of colours without toning, were removed by the proposed preliminary bath of hydrochloric acid, but much additional experiment was necessary to fully determine the conditions under which the influence of the support was felt in the general colour. In conclusion, it was pointed out that, unless fairly fresh paper was used, little success was to be expected.

Mr. C. H. BOTHAMLEY remarked that, in using chromic acid, the nature of the water employed was of some importance, because any difference between bichromate of potassium and chromic acid would tend to disappear if the water contained lime salts, which would at once turn the chromic acid into a chromate. With regard to the image on the paper after the removal of the gelatine, he pointed out that ordinary gelatino-chloride paper always contained a certain quantity of soluble silver salts, and that, when the paper was coated, there was practically a plain sensitised paper behind the gelatine emulsion, and consequently upon development there would be an image similar to that which would be obtained on plain sensitised paper under similar conditions. If one was not satisfied with the red colour of some of the examples shown by Mr. Sterry, it was good to know that that was the best colour to submit to subsequent toning.

Mr. CHAPMAN JONES said the graduated prints exhibited by Mr. Sterry showed that different manufacturers succeeded, in different degrees, in avoiding the penetration of the soluble silver into the paper support. He thought the scientific interest of the paper would be greatly increased if it were possible to obtain information as to the exact nature of the papers with which the experiments were made.

Mr. T. E. H. BULLEN said he had made a number of prints very rapidly and successfully by Mr. Warnerke's method of development with gallic acid. With regard to Mr. Drinkwater's process, he did not find that bichromate of potassium answered well; he had not, however, followed the instruction to print for thirty, sixty, or ninety seconds in sunlight, because his experiments absolutely proved that it was impossible to get a developed print which would tone with such short exposures. Each paper, and each batch of paper, required different treatment.

The Rev. F. C. LAMBERT asked whether Mr. Sterry could tell him how to get pure black-and-white prints on P.O.P. by development alone.

Mr. BOTHAMLEY remarked that the gallic process, used by engineers for the reproduction of plans and drawings, gave excellent black-and-white prints, and was worthy of more attention than it received.

Mr. STERRY said he did not know how to get pure black-and-white on gelatino-chloride paper, the tendency to green in the blacks being apparently insuperable.

#### PERSULPHATE OF AMMONIUM AS A REDUCER.

Mr. ERNEST MARRIAGE showed a few slides to illustrate the action of persulphate of ammonium in the reduction of excessive density. The slides had been treated (generally when dry) in a five per cent. solution of persulphate, and the shadow detail had been well brought out without loss of detail in the high lights, the colour being changed from red to grey. The time of immersion varied from ten to fifteen minutes.

Mr. BOTHAMLEY said he had made a few experiments with persulphate and found it an exceedingly valuable reducing agent; he tried it with some under-exposed and practically useless negatives of interiors, and was a good deal surprised at the way in which it tended to wipe out the dense parts of the image while scarcely touching the fine detail. The exact strength of the solution did not much matter, as long as it was not over five per cent.; as it slowly decomposed in solution, it was advisable not to make up more than would be used within a short time.

The thanks of the Society were accorded to Mr. Sterry and Mr. Marriage.

**Croydon Camera Club.**—Australia has ever been known as of anomaly land, hence the strange and peculiar fauna depicted by Mr. W. Saville Kent at the above on Wednesday, January 18, and the often curious habits and customs described were full of matter for remark and wonderment. How the Southern bear sleeps, hunched on to a nearly perpendicular branch, how the Southern bird builds a nest thirty or forty feet in diameter, and how the Southern ants put up tenement houses for themselves twenty feet high, are just one or two samples of the kind of curiosities of animal life shown. Perhaps the most remarkable of the many natural-history specimens dwelt upon were the lizards. Thus the extraordinary thorny lizard, the bearded one, and another fearsome little specimen which, when approached by any threatening animal, opens a kind of reptilian umbrella and makes such a face that the boldest sporting dog quails and turns tail, were vastly appreciated. The chameleons—though not Australian—shown fly catching were also distinctly good, as were some snapshots of sprinting lizards, which stand up on their two hind legs and run twenty or thirty yards at a stretch. Can it possibly be that these little fellows are trying to evolve into a new type of man? If so, even the new woman will, later on, have to take a back seat. Fish which seemed like the creation of feverish nightmares, wonderful acres of coral reef, and many other captivating photographs were also shown by the lecturer, who was not only followed with much attention by a large audience, but received an enthusiastic vote of thanks at the instigation of the President (Mr. Hector Maclean).

**Hackney Photographic Society.**—January 17, Mr. W. Rawlings presiding.—The Excursion Secretary announced the result of the excursion lantern-slide competition, of which Mr. C. H. Oakden had acted as Judge, as follows: 1st, Mr. W. Selfe; 2nd, Mr. F. W. Gosling; 3rd, Mr. J. E. Hull. Mr. Gear demonstrated the method of

**DEVELOPING NEGATIVES WITHOUT A DARK ROOM,** which had been introduced by Mr. Howard Farmer. This consisted of adding to the developer a certain deep orange-coloured solution, which acted as a light-filter, and allowed a negative to be developed in the light of an ordinary room. This process would be a great convenience for testing exposures when away from home, and where, perhaps, no dark room was obtainable. To show that this method of development was applicable even with the use of energetic developers, Mr. Gear developed at the meeting two negatives with a strong solution of rodinal plus the colouring solution. The plates were developed in the full light of the meeting room, and when finished showed no signs of fogging. The coloring matter had no effect on the developer beyond staining it, and the trace of colour remaining in the film after fixation was quickly removed in the after-process of washing.

**West London Photographic Society.**—January 20, Mr. H. Selby (President) in the chair.—Mr. James Brown (Hon. Secretary) read a paper on

**THE PRODUCTION OF WARM TONES IN BROMIDE PAINTS.** [See page 57.] The hot alum and hypo process was demonstrated, and a number of enlargements toned by that method, kindly lent by the Eastman Company, were exhibited. Toning methods, in which the print is bleached and subsequently redeveloped were fully described, and numerous prints so treated were shown.

**Birmingham Photographic Society.**—January 17, Annual General Meeting.—Sir J. B. Stone, M.P., who has been President for six years, took the chair in that capacity for the last time. In moving the adoption of the report Sir Benjamin said photography had been applied to scientific and educational uses, and to a variety of forms of pleasure and enjoyment. They had seen in recent years the growth of the photographic taste and the camera in evidence in every possible quarter; but, with all the possibilities of the art, he did not think sufficient progress had been made to justify the energy and expenditure that were constantly going on in photographic materials. His parting advice to the members of the Society was that they should take the opportunity at their annual Exhibition of putting before the world the various uses to which photography can be applied, and the members might emulate each other in producing a series of scientific slides or pictures that might answer either for a public lecture or for instruction in the elementary schools. There was such a vast field still open for photographic work that he could not conceive they had exhausted their operation as leaders of public opinion. As a Birmingham Society they were proud of the Warwickshire Survey, and he was gratified beyond measure that this survey work had spread far and wide, and was being done in an excellent way throughout the country; and, whilst he had always been a strong advocate of record work, he had never had any selfish notion that the work should be confined to a particular collection or a particular locality, but, when he advocated that they might send interesting records to the British Museum, he did not withdraw his first love for doing it for their own locality first. The reasons for making photographic records increased, to his mind, the more he studied them. In past times waves of destruction had passed across this country, which had done much harm to us as a civilised nation, and they could not measure the incalculable loss, the destruction of ancient monasteries, and abbeys, and ecclesiastical memorials had been to us. In the reign of Edward VI., for instance, an act was passed to destroy and absolutely do away with all graven images and books, and that act was carried out by the public to such an extent as practically to destroy all valuable ecclesiastical work that had been erected up to that time. Greyfriars Church was filled with magnificent work of architecture and design, monuments erected to great men, but not only did the people enter the church and deface the monuments, but they were sold to an eminent alderman of the day for 50*l.*, who broke them up for road metal. How valuable would have been photographic records of the beauties of these monuments. The men of those days, he reminded them, were as cultured, as eminent, as skilful, and as thoughtful as those of the present day, and they were not to think that, because they lived in the nineteenth century, such things could not happen again. He urged them strongly to continue the work in which they had taken such an excellent lead. Mr. J. F. Hall-Edwards seconded the motion. He emphasised the importance of the scientific side of photography, and added that he would like to see a school of photography established in Birmingham. He hoped this would be one of the first movements in connexion with the Birmingham University—a university, by the

way, which was being founded on lines with which he did not altogether agree. Such a school was very badly wanted. The report was adopted. The following officers were elected:—*President:* Professor F. J. Allen (Mason College).—*Vice-Presidents:* G. F. Lyndon, J.P.; J. F. Hall-Edwards; T. W. Robinson, and E. Underwood.—*Treasurer:* Richard Haines, M.A.—*Hon. Secretary:* C. J. Fowler.

**Bradford Photographic Society.**—This organization held its Annual Meeting at the Bradford Grammar School on Monday, January 16, the President (Mr. Alex. Keighley) in the chair. There was a fair attendance. Mr. KEIGHLEY opened with a few remarks about the Society and its welfare. It had been in existence, he said, just four years, and during that period many interesting lectures and meetings had been held. He felt certain that the Society had been of great use to photographers by providing them with a means of seeing the work of others and exchanging opinions; but, had it achieved no other work than the Yorkshire Photographic Exhibition, he considered it had established a right to exist. The Exhibition had not, of course, been entirely the work of the Bradford Photographic Society, still the larger share of the work and organization had been accomplished by its members. The SECRETARY (Mr. J. Snowden) read the annual report, which showed that the Society was in a flourishing condition. The TREASURER (Mr. F. Nicholson) brought forward the balance-sheet, which showed a small amount to the credit of the Society. The following new officers were then elected:—*President:* Mr. Percy Lund.—*Vice-Presidents:* Messrs. Alex. Keighley, F.R.P.S., F. J. R. Sutcliffe, R. J. Appleton, W. Halstead, Frank Nicholson, and Oliver Nicholson.—*Committee:* Messrs. Rogerson, Liebrich, Geo. Thistlethwaite, W. A. Tetley, Wainwright, Kelsall, A. Hewitt, J. W. Bateson, and A. Hampshire.—*Hon. Lanternists:* Messrs. L. Cooper and C. W. Maw.—*Hon. Librarians:* Messrs. H. Akam and A. Hewitt.—*Hon. Treasurer:* Dr. David Stephenson.—*Hon. Recording Secretary:* Mr. F. Woodall.—*Hon. Business Secretary:* Mr. Ezra Clough. After the election Mr. PERCY LUND proposed that a very cordial vote of thanks should be given to Mr. Keighley, the retiring President, for his excellent services during the past four years. Mr. Keighley was one of the most prominent amateur photographers of Yorkshire, and he had done much, both in the Club and out of it, to encourage an interest in photography as an art. He hoped that, although Mr. Keighley was vacating the presidential chair, he would not lose interest in the Society, but would still, in spite of living at some distance from Bradford, be present at many of the meetings. Mr. GEO. THISTLETHWAITE seconded the proposal, which was carried with acclamation. An excellent series of lectures and demonstrations had been arranged for the remaining half of the season. Those interested in any branch of photography, whether ladies or gentlemen, are cordially invited to become members. The meetings are held every Monday evening at the Grammar School at eight o'clock.

JANUARY 23.—Mr. P. R. SALMON gave a lecture, entitled

#### PALESTINE AS I SAW IT,

illustrated by 150 slides. Mr. Percy Lund presided. The Chairman said they were all pleased to welcome the lecturer, an old member and friend of the Society, who needed no introduction. He was pleased to see such a large attendance and to have such a long list of new members to propose for election. He invited any one interested in photography, whether ladies or gentlemen, to join the Society, which he was pleased to say was in a very flourishing condition. Mr. Salmon, who is in the employ of Messrs. Levy et ses Fils, Paris, in commencing his lecture, stated that some of the slides were taken with a stereoscopic camera and others with a hand camera. The slides which were made by the special albumen process, for which his firm is so noted, were of excellent technical quality and great pictorial merit. Some of the principal views were of Jerusalem, including the Mosque of Omar and the Mosque El Akse, Bethany, Bethlehem, Mar Saba, Ain Karim, Nazareth, Shiloth, Nablous, Sidon, Acre, Tiberias, Magdala, and Damascus.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### PLATINOTYPE PRINTING.

To the Editors.

GENTLEMEN,—I notice that several of your readers have made inquiries as to the cause of certain peculiar lines and mealiness in platinum prints.

I myself have been so troubled, but have got a remedy at last, though what the cause is I cannot say.

To those using Platinotype Company's paper I recommend the following developer and conditions:—

Neutral oxalate.....	12 ounces.
Weak hydrochloric (3 ounces to 80 ounces of water).....	20 "
Make up with water to.....	80 "

Heat developer when using to about 70°, even hotter can be used.

The negatives should be plucky for this formula.

Your readers may think this is for hot-bath paper, but I have used it as given here on the A A paper for some time.

I should be glad to know from any who try this what success they meet with.—I am yours, &c.,

ALFRED E. BUTLER.

Ormonde Villa, Warleigh-road, Brighton, January 28, 1899.

## To the Editors.

GENTLEMEN,—Relative to meanness in prints, if "C. O. & D." does what he says he does, i.e., "pass my prints through the solution in the usual way," the meanness is accounted for. It is not advisable to save time by developing platinotype prints from the back as well as the front, and they should be merely floated, face downward, on to the surface of the developer, keeping the back of the prints dry, at least until the front is quite wet. The print may be at once picked up and held in the hands until development is complete. All this is "the usual way," but some people always know better than to follow the maker's printed instructions, and then grumble (because they get into messes inexplicable) to said makers and to every one else. Of course, "C. O. & D." may not be one of these.—I am, yours, &c.,

T. H. M.

## To the Editors.

GENTLEMEN,—I notice that three of your correspondents seem to be in some difficulty with their platinum prints, although, personally, I have been very successful with them. I think some discussion on this subject would benefit printers generally. According to C. O. & D. he has apparently used oxalate only. I think, if he used biphosphate of potash (perhaps this is not so widely known as it should be), he would be pleased with the result. I know from experience it is far better; if he added three-quarters of a pound of the biphosphate to his stated formulae, he would find his troubles disappear. I think it quite possible that he may be slightly over-printing, and stopping development directly the image appears, and thus causing the mealy appearance. If he accurately follows up the Company's instructions, he cannot fail to get good results. I think the secret of platinotypes lies in the depth to which the printing is carried; that is everything, and it is only gained by careful practice. I have used the Company's paper for the past two years, and never found it at fault. "Printer" is troubled with lines running through the print; I have seen a few of them and believe it to be something to do with his padding, as he says the lines appear before the print is half off the negative; this is how I have found it. Platinotype printers must remember that damp renders the paper useless, that they must be printed the right depth; it, of course, varies with the quality of the negative, and the temperature for the cold-bath developer should not be below 80°. I have found the D. salts superior to the ordinary oxalate developers.—I am, yours, &c.,

H. J. HEWITT.

1 Sycamore-terrace, Bootham, York, January 20, 1899.

## To the Editors.

GENTLEMEN,—Re platinotype printing troubles. My advice is, Order all required in hot bath (A) of the Platinotype Company. Judging from my own experience, all the troubles complained of will vanish.—I am, yours, &c.

ONE WHO HAS BEEN THROUGH THE MILL HIMSELF.

## MODERN FALLACIES, &amp;c.

## To the Editors.

GENTLEMEN,—I sympathise with your desire for strict accuracy, hence it is that whatever I write in the photographic and other technical press is the result of honest personal study and experience. I find it difficult to understand, therefore, why I am specially selected for the pillory.

Premising that I am not so ignorant as you appear to infer of the composition and properties of sel-d'or (nor the manner and purpose of its introduction), I should like to point out that, although the writer of the article in question has quoted me correctly, he has not attached the significance to the word "combined" that I did.

I imagine that, when M. Fizeau, to whom we are indebted for the introduction of the double salt of gold and soda, "sel-d'or," that is, called attention to its properties, the bath was made up by those who used it on the spot by mixing solutions of gold chloride and soda hyposulphite. Later on would come the tubes of sel-d'or, but many would still make it in the old way. It is easy to see that from the simple solution to one containing phosphate of soda and an excess of hypo, with the object of combining the operations, was only a step; that, as a matter of fact, the old combined bath, which figures in all old ALMANACS OF THE BRITISH JOURNAL OF PHOTOGRAPHY, is all that remains to us of the old hyposulphite of gold and soda toning bath. It was very frequently mentioned by old photographers, as I can very readily remember, as a hyposulphite toning and fixing bath, not to be recommended, however, on account, so they said, of the non-permanence of the results without an after bath of hypo, and some openly referred to it as a "sel-d'or" bath, and I am quite sure that it was a sel-d'or bath, "inasmuch as it contained a solution of gold and soda hyposulphite" "combined" with other salts.

There is no doubt, as you say, that "sel-d'or," a rather elastic term by the way, was the name given to the double salt of gold and soda introduced by M. Fizeau for the purpose of toning Daguerreotypes; but, so long as we use chloride of gold and hypo soda in a combined toning and fixing bath, we cannot forget the "salt of gold." Some people would

say that to nothing else are we so much indebted for all the faded silver prints of the years gone by. I am not anxious, of course, to defend the bath in any way; it was useful for wet-collodion slides, but prints very often displayed signs of sulphur toning.—I am, yours, &c., J. PIKE.  
Nottingham.

## THE ROYAL PHOTOGRAPHIC SOCIETY AND PROFESSIONAL PHOTOGRAPHERS.

## To the Editors.

GENTLEMEN,—As a "bread-and-butter man" I venture to write you about the R.P.S. election, the third Yorkshireman who has done so. That the R.P.S. has made mistakes in the past is admitted. Sometimes those mistakes have been made while trying to improve things. Few professionals exhibit now at the R.P.S. or anywhere else. Why? Because most of those who used to exhibit have found the game not worth the candle. Only the other day, the R.P.S., or as it was then the P.S.G.B., saw that retouching and touching up was being carried on to such an extent that the Judges at the annual examination were bothered to know which was photograph and which was paint; so they decided to encourage the exhibition of pure, that is untouched, work, as, after all, the Judges were men who knew more of photography than of painting and retouching, and to this end refused to honour any photograph, no matter how good, which showed signs of hand work on negative or print. The result was that very many of the best professional exhibitors took offence and showed no more. Not that I think the Society was wrong in putting down retouching, but I am in the minority here.

Then the R.P.S. made a mistake more recently, it began to create Fellows of the R.P.S., but was not particular what the Fellow knew of photography as long as he had two guineas in his pocket. When this honour was offered to us bread-and-butter men for a certain sum of money, we felt astonished, for the average Englishman has a sense of honour left in him, and there are certain things which he thinks should not be bought with a price, but won by hard work; and then two guineas is two guineas. Now, when we saw how certain photographers bought this honour and advertised the purchase in large gilt letters on the front of their mounts, underneath work nine-tenths of us would have been ashamed to send out, we felt more sorry than ever for the R.P.S. In fact, if a Fellow of the Royal College of Surgeons had made such a bad job of a patient as one portrait I saw lately, signed F.R.P.S., I am sure the Fellow would have been asked to resign.

There are some points in Mr. Percy Lund's letter which I think require comment. May I comment? Mr. Lund is sorry that professionals will not unite. They never will. Why? Because their ranks are continually being recruited by men who are bound by no laws or traditions. Twenty years ago—before the deluge—with the amateur such a thing might have been possible, to-day it is not. Supposing all the photographers here unanimously decided to give only two instead of three cabinets for half-a-crown, to-morrow there would be a new studio with an amateur in it doing them at the old rates.

Look at the National Association of Professional Photographers! This body found it impossible to make photographers unite, they could not even agree about the most suitable meeting places; some were thirsty, and others thought all distillers and brewers should be potted at sight.

The last paragraph but one in Mr. Lund's letter is the one I find it hard not to agree with. If I am not mistaken, the "others" have been going to the wall, according to certain writers, for years; but it does not require much observation to find that it is this class of photographers who is doing, and has done, most of the trade. For one person who is an artist and has cultivated taste there are thousands who never bother their heads with the fitness of things. To be sure, photographic dealers are greatly to blame for pressing on to photographers in the good old days impossible and abominable accessories and backgrounds, for much of the bad taste which abounds, which our patrons seem to think necessary to make up a perfect photograph, and unless we can provide an artificial palm tree, a sham terrace wall, a stuffed poodle dog, and a castellated mansion behind, people go where such things are to be had. They would rather suffer the torture of the head-rest, and be twisted into ridiculous attitudes, and be highly polished by the retoucher, than be taken naturally, and say that they never enjoyed sitting for a portrait before. When I was young, I hoped as Mr. Lund hopes yet, but hope deferred makes the heart grow sick. Excuse all this.—I am, yours, &c.,

Whitby, Yorks, January 20, 1899.

FRANK M. SUTCLIFFE.

## THE CROYDON CAMERA CLUB AND THE AFFILIATION.

## To the Editors.

GENTLEMEN,—Currency having been given to unfavourable and *ex-parte* statements which seek, by making damaging reflections upon the Club and myself, to minimise the effect of the Club's resignation of membership in the Affiliation, I ask you to give us the privilege of explaining in your widely-read JOURNAL how it happened that the Club revolted.

The combination of societies for mutual help and encouragement was,

no doubt, at the outset a very fascinating idea, full of valuable possibilities.

What has this alluring project developed into? Nothing much beyond sterility and destruction. Almost from the very beginning the Affiliation has been notoriously captured and run by a log-rolling gang, which, regardless of outsiders, has played for its own hand. Let me cite some amongst the least objectionable instances.

Take the *Judges' Regulations*. Here, instead of the main object in view being to aid and safeguard the interests of the affiliated societies, the controlling gang drew up a set of rules almost solely in the interest of what are called "Judges" and of exhibitors. All kinds of vexatious restrictions and obligations have been thereby imposed upon societies by this precious one-sided document, which it is not surprising to know has more than once been contemptuously passed over by those who possess a spark of independence.

Another impertinent inference, by the photographic equivalent of "The Three Tailors of Tooley-street," was made on behalf of certain amateurs who want to have money forced upon them for unsaleable lantern lectures. This tampering with freedom of contract, so far from being helpful, is most distinctly detrimental to the activity and welfare of photographic societies. In connexion with this point it is somewhat surprising to find that, as regards compulsory payment for lantern lectures, the Royal Photographic Society, which is the parent of the Affiliation, does not even pay "the expenses" of all those who give lantern lectures at its exhibitions, this notwithstanding that it is guilty of taking "money for admission."

Amongst other things which have riled the Club was the cynical way in which the Affiliation filched the credit derivable from a first communication of Mr. James Packham's notable researches on *gum-bichromate printing* to the Croydon Camera Club.

A paragraph in a contemporary also reminds me of the high-handed way in which the Affiliation, several years ago, took advantage of the carelessness of our then Secretary, when, in consequence of our subscription being a few weeks or so overdue, the Club was actually struck off!

This general policy on the part of the Affiliation of being as harmful and ill-tempered as possible has certainly tired out our patience. Even to the very last the Affiliation, so far from welcoming help in return for offers of aid, flings back mud. The assertion which has been made is, however, not true that I have been canvassing (*i.e.*, soliciting votes) for an Affiliation lecture. The real facts of the matter are that, reading that lectures on certain subjects were desired for circulation, I informed the Chairman that I should be pleased, if called on, to furnish one on a particular subject with which I am familiar. On his replying that the initiative rested entirely with the delegates to nominate and invite lecturers, the matter, as far as I am concerned, dropped, and I took no further steps. I was not even aware that any one but Mr. Thomas and myself knew of my offer. I suppose, in the ordinary course of business, at some meeting, the subject cropped up, and my offer thereby became known to some of the delegates, who, however, could make no better use of it than to inspire spiteful comments.

By the way, had Mr. Thomas continued the chairmanship, it is quite possible that the Club would have gone on putting up with the unpleasant ways of the Affiliation out of regard which many of our members have for the late Chairman. As it is, we sorrowfully resign the inestimable privilege of half-price exhibition tickets; and, as our members prefer to take their sleep in bed, also forego the Affiliation circulating lectures.

Other societies may find it worth while to swathe themselves in Affiliation red-tape, and feed off the photographic pap sent out, but we of Croydon prefer more freedom, and stronger, fresher meat; and so we intend to "gang our own gait," indifferent whether or not we thereby provoke another "severe indictment of the management of the Society," being quite content with our continuous growth, our financial prosperity, and with the abnormal interest taken in our meetings by the general body of members.

I should add that I took no part in the discussion at our Council meeting which decided the resignation, I was utterly unaware the question was going to be raised, and that not a voice was lifted up in favour of the Affiliation.—I am, yours, &c.,  
HECTOR MACLEAN.  
Croydon, January 24, 1899.

## THE METRIC SYSTEM.

To the Editors.

GENTLEMEN,—I have had the gratification of reading the notes on the metric system published in your issue of the 13th inst., and note with thanks your suggestion that I should send to Professor Sweet a copy of the report recently issued by this Association.

It will probably interest you to learn that there exists in the United States a society which advocates the adoption of the metric system. The President of it is Professor Mendenhall of Worcester, Mass., the writer of the accompanying pamphlet, and I am to-day writing to that gentleman, calling his attention to Professor Sweet's remarks.

I think Professor Sweet is wrong when he says the manufacturers are against the metric system. I spent twelve months in the States in 1897-8, and I found several manufacturers, or makers of machinery, who

were in favour of it; indeed, I found some who use it in their works, and I believe I could soon obtain a list of seventy firms who do so use it. They see that, if they are to send their machines to metric-using countries, they must do so.

Further, a Bill for the compulsory introduction of the system into the United States on January 1, 1901, is before Congress now, and I received a letter from the Chairman of the Committee on Coinage, Weights and Measures, at Washington, only a fortnight since, saying this Bill was very likely to pass. The fact that the Americans use the metric system in Cuba, Port Rico, and the Philippines, is helping to bring that result about.—I am, yours, &c.  
E. JOHNSON, Secretary.

The Decimal Association, Botolph House, Eastcheap, London, E.C.,  
January 20, 1899.

[The pamphlet by Professor T. C. Mendenhall, which Mr. Johnson is good enough to send us, is an able defence of the metric system in reply to some criticisms directed against it a few years ago in the *Times* by Mr. Herbert Spencer.—Eds.]

## 1899. FORTHCOMING EXHIBITIONS.

- January 27-31..... Perthshire Society of Natural Science. C. F. S. Burrows, Hon. Secretary, 16, Princes-street, Perth.  
,, 30, 31..... Southsea Amateur. F. J. Mortimer, Cornwall House, Ordnance-row, Portsea.  
February 4-25..... Edinburgh Photographic Society. Hon. Secretary, J. S. McCulloch, 2, George-street, Edinburgh.  
,, 13-18..... Photographic Society of Ireland. Hon. Secretary, 35, Dawson-street, Dublin.  
,, 21-24..... Hastings and St. Leonards. Exhibition Secretary, A. Brooker, 21A, Wellington-place, Hastings.  
,, 23-25..... Woolwich Photographic Society. Hon. Secretary, F. W. Machen, 161, Griffin-road, Plumstead, S.E.  
,, 27-March 4. Birmingham. C. J. Fowler, Court Mount, Edington, near Birmingham.  
March 4-11 ..... South London. Hon. Secretary, A. E. Allen, 27, Princes-square, Kennington Cross, S.E.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

J. Clapperton, 23, Albert-place, Galashiels, N.B.—Photograph of Dr. Wm. H. Murray, of Galashiels.

J. A. Horsburgh, 4, West Maitland-street, Edinburgh.—Photograph of The Right Hon. Lord Saltoun, of Philorth, Aberdeenshire, as Grand Master Mason of Scotland in Masonic dress.

D. K.—You have omitted your name and address; consequently, according to our rules, your question is not answered.

F. BEECH WILLIAMS.—Register the photograph forthwith and place the matter in the hands of a respectable solicitor. You will then have no difficulty about recovering.

ROBERT ROBY.—1. We should certainly recommend colour-corrected plates and a screen. 2. The Bausch and Lomb Ray-filter. 3 and 4. Edwards's Snap-shot Iso.

J. A. H.—1. Platinotype paper is usually meant, although the letters are occasionally employed to indicate collodio-chloride. 2. The papers named are *gelatino-chloride*.

J. D. G.—The Strand Engraving Company, Strand, W.C., would undertake the work. The price ranges from 6d. to 1s. 3d. per inch. You would probably be charged about 8d.

JOHN RELPH.—1. There are several solvents of celluloid which would answer your purpose; probably acetate of amyl would do best. 2. We know of no special preparation for the purpose.

X. Y. Z.—Your communication is far too personal, and too offensive for admission into our columns, even if your name, as the writer, were attached to it. Even that you have not the courage to do, it seems.

MOUNTANT.—H. GRIFFIN. Nothing beats freshly made starch paste as an all-round mountant. The mountant named is a convenient one to use, but as it is a trade preparation, and we do not know its composition, we can express no opinion as to the effect it may have on prints mounted with it one way or other.

LANTERN.—C. A. CROSS. The unevenly lighted and partially coloured disc on the screen shows that the light is not properly centered, and is not at the right distance from the condenser. First see that the light is accurately centered with regard to the axis of the optical system of lantern, then move it backward and forward till an evenly illuminated disc is obtained.

**FLASHLIGHT.**—T. LAMBERT. The composition referred to will give an excellent artistic light, and of very short duration. The "flash" is very much of a small explosion, and we should advise you to be very careful with the mixture, for fear of accidents. Better keep the ingredients separate, and then mix only just before using, employing only a strip of cardboard for the mixing. It is one of the most dangerous of the flashlight compositions.

**BURNISHER.**—WRECKED says: "My Globe enameller marks my prints in several places through minute digs in it; will you oblige in your answer to Correspondents? 1. Is there a remedy? 2. Can I get a new bar and where shall I write for it? Thanking you in anticipation."—1. If the "digs" are not too deep, they can be worked out on an oil-stone—working the bar longitudinally along the stone. 2. Those who supplied the burnisher will, doubtless, supply a new bar.

**PHOTOGRAPHIC CLUB.**—C. X. There is no difficulty whatever in gaining admission to the Photographic Club either as a member or a visitor. As the former, you have only to be proposed by a member and seconded by another. As a visitor, you will be admitted by the introduction of any of the members, or the Hon. Secretary will be pleased to send you a ticket of admission to any meeting on application. Address, W. R. Stretton, Esq., 4, Queen-street-place, E.C.

**TENANCY.**—WARWICK. As you took the tenancy on a three years' agreement and no fresh one was made, it seems to us that you have since been a yearly tenant, and subject to the six months' notice you received at Christmas. Unless there was an agreement to that effect, you cannot claim any compensation with regard to the studio you built. Surely you did not build a studio and other premises on the strength of a three-years' agreement? If you did, it was very remiss on your part.

**WINTER PHOTOGRAPHY.**—J. FROST facetiously writes: "I was much interested in your valuable hints re winter photography, and how to turn it to profitable account. It would be equally as interesting and valuable if you would tell us when we shall have a winter when we can make use of them, which I certainly shall when the opportunity occurs!"—We are afraid we must refer our facetious correspondent to the Clerk of the Weather for a reply, as it is "beyond our ken."

**CINEMATOGRAPH.**—1. Impossible to answer satisfactorily. We have seen films that have been passed through the machine hundreds of times and yet have remained in good condition. No definite guide can be given—all depends upon the care and skill of those through whose hands the films pass. 2. The subject is fully discussed in a useful little book, *Animated Photography*, by C. M. Hepworth, published by Hazell, Watson, & Viney, 1, Creed-lane, E.C., price 1s. We recommend you to procure this.

**TONING BATH.**—G. HORNE asks: "Can you, through your valuable paper, give me a formula of a thoroughly reliable toning and fixing bath combined, one that will keep for retail purposes? We should require three or four gallons at a time. It must be one solution, as the amateur likes that best. Thanking you in anticipation."—We know of no reliable combined toning and fixing bath that will keep, because in time the gold would become reduced, and, after that, what tones were obtained would be due to sulphur toning and not gold toning.

**STUDIO.**—J. M. writes: "I purpose building a new studio 30 feet by 19 feet. Light east. Would 8 feet of length, glazed on east side, as shown in sketch, give ample lighting? Would it be an advantage to have whole of east side glazed? Will it be necessary to have part of west side glazed also, in order to avoid direct sunlight in early part of day?"—Ten feet would be better, particularly for taking groups. It would also be convenient at times, say, early in the morning, if the west side were also glazed. If both sides are glazed, there will always be the option of lighting the sitter from either side.

**SPOTTY PRINTS.**—SPOTTER. "I have been greatly troubled lately by spotty prints like the enclosed; could you inform me the cause of them? I use sulphocyanide bath, hypo quarter of a pound to the quart of water, and twenty minutes fixing. The spots do not appear until the prints are mounted and dry."—Several causes will produce spots similar to those on the enclosed prints, but which of them has been the cause in this instance, when no data to form an opinion upon are given, it is impossible to say—beyond faulty work. We notice, however, that the fixing bath used is but half the strength usually employed. That may have, with other causes, contributed to the spots.

**SENSITISING BATH.**—R. SUMNER writes: "I am only an amateur, and am trying albumen paper. Having read that home-sensitised paper gives better tones than the ready-sensitised, I have been trying my hand with that, and I certainly prefer it. The bath is 60 grains to the ounce; but, after using it two or three times, it becomes a dark colour, and that with each lot I have used, which means to me a great waste."—In reply: There need be no waste whatever. All that has to be done is to add a little kaolin to the solution, then well shake for a minute or two; the solution will then, after resting a few hours, be quite discoloured and as good as at first if filtered. The kaolin may be left in the bottom of the bottle, as it does over and over again.

**STUDIO LIGHT.**—A. MARTIN says: "The studio I am working in I can only work one end, the shadow side covered in and three feet top and side, the end I work with, covered with dark curtain; please inform me the best way to light a sitter. Should I place them direct under the top light or place them nearer the background; an answer will oblige!"—The sitter should certainly not be illuminated by a direct top light. Not knowing the form of the studio or its aspect, we can offer no advice. Of course, each sitter requires a different lighting to suit the features and the effects desired. We should advise you to get a professional in your neighbourhood to give you a few lessons, as you appear to be ignorant of the subject of lighting.

**COPYRIGHT.—FAIR PLAY.** You certainly cannot prevent your competitor from showing an enlarged portrait of one you took, and selling reduced copies of that if he likes. You received "a valuable consideration"—were paid for taking the portrait, which the sitter can do as he likes with. He has given your townsman permission to do what he is doing, and why should you have any voice in the matter?

**MONIQUE SURGENS.**—1. On examination some time ago we found it useful and practicable. 2. We safely changed very rapid plates in it in the open. 3. Yes. 4. The film there mentioned is a rollable one; but we have used stout celluloid specially surfaced for focussing purposes. The fine grain is in its favour, and you do not run the risk of breakages. One lies on our table as we write this which we have had in use for years.

**WORKING HOURS.—EMPLOYÉ** writes: "What is the rule with regard to working hours? When I was engaged, the hours stated were to be from half-past eight to half-past six, with an hour for dinner. During the winter months there is nothing much to do after dark, but — & Co. will not let us leave till half-past six. Is it not usual for employés to leave off at dark?"—If there are stated hours in the agreement, they should be abided by both winter and summer. We presume the firm will not expect you to remain after half-past six in summer, though much might be done after that. When employés are allowed to leave earlier in the dark days of winter, they are expected, *quid pro quo*, to stop later in summer if there is work to be done. But an agreement is an agreement, and should be adhered to.

**STUDIO WITH SOUTH ASPECT.**—REX writes: "I seek your valuable advice in an important venture I have been contemplating. I am a young photographer, and am desirous of opening a studio of my own. I have the offer of premises in a good position at 30l. a year rental, with lease. I should have to knock the building about to get my studio, there not being sufficient yard room to erect one. When I have done this, there will be a south light. Would you advise me, all other conditions being favourable, to refuse the offer on account of the light being south? I should be very grateful if you would let me know your views in this week's JOURNAL, as the landlord is waiting for my decision."—Very successful portraits can be, and are, taken in studios with a south light. Such studios are a little more troublesome to work, at times, than those having other aspects. There is no reason why, if you are a skilful photographer, the premises, if otherwise suitable, should be rejected on account of the south aspect.

**MATT ALBUMEN PRINTS.**—F. C. writes: "Would you have the kindness to help me out of a difficulty I seem to be unable to abridge? I am endeavouring to turn out albumen prints (with a special warm tone I obtain) with a dead matt surface, collodionising the glass as for ordinary bright enamels, only on ground glass or matt opal. However, I cannot seem to meet with any success. First, the collodion film used to split, and I always find them inclined to come off the plate too soon, i.e., before dry. When they come off, the surface has not taken that of opal—only to a slight degree—and there seem frothy, bubbly marks all over, although every precaution was taken. I regret that I cannot tabulate this query into numbered questions, as I do not know exactly what to ask, but shall be very pleased if you will kindly do anything to help me to do what I am striving for. Thanking you in anticipation."—It seems to us that, in using collodion, you are increasing the gloss you are anxious to get rid of. Have you tried working without the collodion? The next thing we should suggest is to use but a lightly albumenised paper, and squeegee that while wet on to finely ground glass, or, better still, use plain salted paper or paper prepared with diluted albumen, say, one part of albumen to two of water.

**ILL EFFECTS OF METOL.**—GOLFER says: "To facilitate the turning out of my orders in these dark and unprintable lighted days, I had to go largely in for Velox papers, which I got splendid prints on, using their special portrait paper and the following developing formula, which is very near 'Barnet' formula for their bromide papers, namely: A.—Metol, 100 grains; soda sulph., 2 ounces; pot. brom., 16 grains; aqua, 20. B.—Potass. carbonate, 1 ounce; water, 20 ounces. For developer use 3 parts A to 1 part B. The only drawback has been that these chemicals have seriously affected my fingers in lifting the prints, the skin turning white, as if burned, and a dead or want of sensitiveness feeling; while there is no pain, there is a burning or itching sensation in the part affected. After a time the skin peels off, but, before this takes place, the skin cracks before the under skin has had time to grow, and exposes the flesh, and, should it be under the nails, which is often the case, a good deal of pain may take place. I may state that I have used finger stalls, but even this does not prevent it, as the stalls roll up in taking off, and in time get saturated with it on the inside, and it is then worse than ever, as the whole finger is affected. Is it the metol or potass. carbonate that is the cause? So many use Velox paper, or, I should state, metol developer, that you will be conferring a great benefit if you will kindly give, first, an antidote; or, second, another formula for Velox paper that will not cause any discomfort to the user. Thanking you in anticipation."—Metol is liable to produce trouble, such as that described, with some people, though not with others. It is very erratic in that way. If the developer recommended by the makers of the Velox paper be employed, and used with a brush as directed, no trouble will be experienced, as the fingers need scarcely come in contact with the solution. India-rubber finger stalls are a certain preventive, if ordinary care be taken that the solution does not get inside them—a very easy matter. Avoid the solution getting inside the stalls, and take the precaution to wash off the developer before the stalls are rolled off. If contact with the metol be avoided, the sores will quickly cure themselves.

\* \* Owing to exceptionally great pressure on our space, we are again compelled to hold over numerous articles, answers to correspondents, &c.

## EX CATHEDRA.

A NOTABLE addition to London studios has just been made by Messrs. Langfrier, the well-known photographers, of Glasgow. The new atelier is situated at No. 23A, Old Bond-street, and on the east side of that fashionable thoroughfare, a position that is unrivalled for the opportunity it affords of cultivating a high-class photographic business. The suites of rooms occupy two floors, and have been specially designed and built for their respective purposes. Access to them from the ground level is obtained by means of a lift, so that sitters and visitors are spared the trouble and fatigue of mounting two or three flights of stairs. We write under correction, but we believe that the new Langfrier studio is the only one in London that affords its clientele the very modern and very acceptable convenience of the elevator.

THE reception room is of noble proportions, measuring approximately fifty feet by thirty feet. It is furnished and decorated in the best taste, and the walls are covered with

a well-chosen selection of Messrs. Langfrier's very excellent portrait work, so that the visitor is made to feel that he has entered a beautiful gallery of photographs rather than the mere ante-room of a photographic studio. In respect of the dimensions of their reception-room we should not be surprised if Messrs. Langfrier had established a record; to our knowledge, there is not another as large in the country. The Langfrier studios have been in course of erection for nearly a year, and have cost several thousands of pounds. They are furnished and fitted throughout, even down to the minutiae and details of the dark rooms, printing rooms, and so forth, with the keenest regard to completeness, convenience, and good taste.

\* \* \*

SPECIAL reference is demanded by the studio; this measures about forty-five by twenty feet, with a height of twenty feet. Instead of being ridged on the glass side, the corner has been rounded off, and the glazing has been carried to the middle of the roof. One end of the studio is occupied by a perfectly built-up stage, having a raked floor, proscenium, curtains, footlights and scenery dock, all complete, for stage photography. A total candle power of 50,000 is obtainable from incandescent lamps, so that any effect of stage lighting can be secured. It is anticipated that even cinematographic pictures will be taken on this attractive little studio stage, the convenience of which to members of the theatrical profession and others must obviously be very great. When in working order, this very fine studio will allow of practically anything or everything in indoor portraiture and group photography being produced in it. The daylight is uninterrupted, and the incandescent electric light is always at hand in emergencies. The Langfrier studio starts as well equipped as enterprise and good judgment can make it, and we wish it the success it merits.

\* \* \*

WE announced some months ago that the West Surrey Photographic Society had organized for its members a novel competition, namely, the photography of fruit or vegetables. The competition has just been decided, and was very successful, thirty-seven prints having been sent in. We are pleased to learn that these prints were of such high average merit that the Judges, in addition to the guinea prize, which went to Mr.

E. W. Burch for a group of grapes, lemons, &c., with a claret jug (an ingeniously selected group, by the way), highly commended the same gentleman's group of vegetables, commended two prints sent in by Mr. Curtiss, and one sent in by Mr. Pointon. The winning prints have been submitted to us for our inspection. Mr. Burch has been wonderfully successful in his tone renderings, and, indeed, all three gentlemen show great skill in their work. We congratulate the West Surrey Society on the success of their interesting competition, which is to be followed by one for a book plate for the Society's library.

A CORRESPONDENT writes to us as follows with respect to Mr. E. Sanger Shepherd's lecture on "Photogravure" at the Camera Club: "I notice in his lecture at the Camera Club, on Thursday fortnight, Mr. Sanger Shepherd mentions Captain Abney's process for making transparencies by sensitising an ordinary unexposed gelatine bromide film with bichromate of potash, and, after drying, exposing and developing as for ordinary carbon tissue, thus producing an image composed of varying thicknesses of bromide of silver and gelatine. So far so good; but why Captain Abney's process? It was published, if I mistake not, by Mr. H. Y. E. Cotesworth twelve or thirteen years ago—at any rate, I know I tried it successfully from instructions published in the JOURNAL about that time. I can, perhaps, nearly fix the date by saying that I used Obernetter's gelatino-chloride print-out paper, which was almost new then, because ordinary gelatino-bromide films, being generally more or less 'alumed,' were, at best, uncertain in action, whereas the perfectly soluble chloride film was quite certain."

The writer goes on to say: "The paper was fluted on, or immersed in, a solution of bichromate in the ordinary way, which turned it bright red owing to the free silver, and this colouration, as pointed out in the article describing the process is rather an advantage than otherwise since it prevents the light penetrating the film too completely. If, however, it be objectionable, an equal quantity of bromide of potassium may be mixed with the bichromate, when the sensitised film will be pure yellow. In either case, when dry it was exposed until the image was fully visible, squeegeed on the glass, and developed in the ordinary way. I showed some lantern slides made in this way from Obernetter paper to the late Mr. Traill Taylor in 1886 or 1887, and I scarcely think the change from that medium to rollable celluloid films can constitute a new process." We have referred to back volumes, and find the process referred to is described by the late Mr. H. Y. E. Cotesworth in an article in our issue for March 4, 1887, p. 132.

DICKENS'S birthday, February 7, will be marked this year by a lecture on "The Real Dickens-land," given in the Assembly-room of the Bull Inn, Rochester, famous as the scene of the ball attended by Tupman, the friend of Pickwick, and the perfidious Jingle. The lecture will be in aid of the restoration fund of Rochester Cathedral, and will be delivered by Mr. H. Snowden Ward. The chair will be taken by the Dean of Rochester. We have seen many of the photographs that will be shown as lantern transparencies on this occasion; they are by Mrs. Ward, and are of remarkably good quality. We understand that Mr. and Mrs. Ward shortly leave for the United States on a lecturing tour, and we have no doubt that not the least popular of the series will be those with "Dickens-land"

for the subject. Our hearty good wishes accompany our friends on their journey.

THE very latest aspect of coupon photography is communicated by a Brisbane correspondent to an Australian contemporary. The circular that is issued reads as follows:—"Important Announcement. The Manager of the ——— Hairdressing Saloon, ——— street, will give to each customer, for Shaving or Hair-cutting, a Discount Coupon. When twelve Coupons have been issued to any customer, he will, on presenting them to Walter E. Perroux, proprietor of the Austral Photographic Studio, receive three enamelled cabinet photos of himself, mounted on Christmas cards or otherwise, and equal in finish to the best produced in Paris or Vienna. The coupons will be transferable, and the issue will be limited to twelve to each person." Coupon photography here at home is "played pretty low down," as the current phrase goes, but we doubt if it has yet reached the depth here indicated.

M. TANQUEREY, the free portrait exploiter of Paris, is irrepressible. In the last batch of literature, which the British Post Office so amiably assists him in distributing amongst people who in all probability get no opportunity of learning the real nature of the man's business, he quotes a number of what he terms "testimonials" from the English press. Extracts from our contemporaries, *Truth*, *The Morning Leader*, and *The Daily Mail* are given which are cleverly made to appear favourable to "Tanqueray." With regard to the first-named paper it is matter of common knowledge among its readers and others that Mr. Labouchere has not hesitated to emphatically denounce Tanqueray and his methods. The quotation from the *Daily Mail* is an extract from an interview with Lady Colin Campbell, who really received an enlarged portrait free of charge, and who, in return, is quoted as saying that Tanqueray "deserves every support from English people!" The lady is scarcely to be congratulated on her choice of a *protégé*. Among the quoted testimonials is the following letter to the *Yorkshire Post*: "I beg to write to say that I had SIX portraits done by Mons. Tanqueray of Paris. The crayons are most excellent and were valued by a local photographer at 80 shillings each. I am still ordering others.—Lewis Mothley, Spen-lane, Kirkstall, Leeds, November 22, 1893." Mr. Warren, the able President of the Leeds Camera Club, who contributes an interesting column on photographic topics to the *Yorkshire Post* every week, would be doing photography in the North of England a distinct service by counteracting the misleading effects such a letter as the above is calculated to have when published in so influential and widely read a paper as the *Post*.

#### DEVELOPING PRINTING-OUT PAPERS.

THE development of gelatino-chloride papers is by no means a new topic, but just recently it has again been brought prominently forward by a paper read before the Royal Photographic Society by Mr. Sterry, and previously by an article in our columns by Mr. W. E. A. Drinkwater. That good results can be produced by this method on some papers is beyond question, but whether it possesses any practical advantages over the employment of the papers specially prepared for development remains to be seen. We have just said that good results are obtainable on some papers, and we emphasise the

"some," inasmuch as many workers, especially amateurs, seem inclined to look upon "printing-out papers" as a definite article, and as being of one and the same composition, whatever the brand. As a matter of fact, there is a wide difference in the characteristics of the various printing-out papers now on the market. Hence it is obvious that the development treatment and formula that will yield good results with one make may not do so with another. Therefore experimenters in this direction should not, in the case of failure, attribute it to either the method or the formula, but rather to their not being adapted to the particular brand they have tried.

Here is another point in connexion with the development of commercial gelatino-chloride papers that should be taken into consideration. In the manufacture and handling of printing-out papers the same scrupulous exclusion of actinic light that is imperative with bromide papers for development is unnecessary; but it is manifest that, if the former are to be subsequently submitted to a developing agent, any trifling actinic action, either before or after printing, will result in more or less fogging of the lights, although it would have no effect whatever if the paper were employed for the purpose for which it was put upon the market, namely, for printing out and afterwards toning. We call attention to this matter, because it may have been the cause of some of the failures of those who have been, at one time or other, experimenting with gelatine printing-out papers and development.

### MINIATURE PAINTING.

THE Society of Miniature Painters, of which Sir William Richmond, the grandson of a miniature painter, is the President, has opened an Exhibition, not the first, at 175, New Bond-street. The Exhibition is, necessarily, not a large one, superficially, but it contains a number of works of considerable merit, which it is not our present purpose to comment upon, beyond saying that portrait photographers will do well to visit it and study the styles of colouring, with the view to the more prominent introduction, or rather reintroduction, of coloured photographic miniatures on a permanent base. There is no question that photography killed miniature painting of a class soon after its *début*. We say of a certain class, for at that time there were miniature painters and miniature painters. There were Cosways and "Miss La Creevy's," so well described by Dickens. However, it is noteworthy that one of the foremost miniature painters of their day, Sir William J. Newton, was one of the founders of the Photographic Society, now the R. P. S. At the inaugural meeting in 1853, under the presidency of the late Sir Charles Eastlake, then President of the Royal Academy, Sir William J. Newton moved the first resolution—"That a Society be now established, to be called the Photographic Society." From this it will be seen, at the first, how artists looked upon photography.

When portraits of the La Creevy type were killed, coloured photographic miniatures, Daguerreotypes, paper pictures, and glass positives came to the front—coloured and uncoloured. Brooches and lockets with portraits, sometimes with the portrait on one side and hair—arranged by "artists in hair"—on the other, were the fashion. At that time a good business was done by the best establishments with coloured miniatures at from one to ten guineas and upwards each; but they were works of art. They were also of a class to be had for

a few shillings. But fashion changed; portrait and hair jewellery went out of fashion, and a feature of coloured photographs, once a very lucrative one for the smaller sizes, was neglected when the *carte-de-visite* mania set in, and has not since been revived with any spirit. Possibly, however, the energy of the newly formed Society of Miniature Painters may give a fillip to coloured photographs, if they are made works of art—not what are now called coloured photographs, done for a few shillings each.

**A Novel Point.**—A few weeks ago we alluded to a matter that may prove an important one to photographers. It was this: In taking some snap-shots of an old inn, a well-known man in the district was included in the pictures, which were subsequently shown before a large audience at the Shettleton Camera Club. It happened that the person in the foreground had a strong objection to being photographed, and threatened legal proceedings against those concerned, and the Club in particular. It now appears that the matter will be brought to a practical issue, for it is stated that the gentleman has actually commenced proceedings, which will shortly be tried in Glasgow, he claiming 150*l.* damages on the ground that, while following his usual calling, photographs of him were taken without his knowledge or consent, and afterwards publicly exhibited. The issue of this case is an important one to photographers, for, if it succeeds, it will materially interfere with instantaneous photography, followed commercially. For example, in photographing a ceremony, as, say, in the launching of the *Oceanic*, hundreds of people must be included in the picture, and, if any one of the number can prohibit the publication of the picture, it will be an important matter; but, possibly, there is more in this particular case than we are aware of at present.

**Art in the City.**—There is shortly to be unveiled another handsome fresco to the adornment of the interior of the Royal Exchange. The new picture has just been completed, and is the work of Mr. Stanhope Forbes, A.R.A. It represents the Great Fire of London, a most appropriate subject for a City picture. The spectator is supposed to be standing by the river side in the vicinity of the old London Bridge, with crowds of excited people filling numerous boats moored to picture-que wharfs. Of course, such a subject is a difficult one to deal with, and is entirely imaginative, but the artist has proved himself equal to the occasion so far as making a fine historical picture from the meagre authentic records available. Slowly but surely the City, which is said to be devoted solely to business and money-making, is acquiring art treasures that may some day be a credit to the chief city of the world. The permanent collection of paintings now at the Guildhall is good, while the annual loan exhibitions always contain some of the finest works in the kingdom.

**Spy Mania in Spain.**—According to a Reuter's telegram, the spy mania has extended to Spain, for, according to it, from Palma, Majorca, a mysterious person, said to be an officer in the British army, is travelling about the island taking photographs. It is also added "that he is under the observation of the authorities at Mahon, and that reports upon his movements are sent every day to the prefect." Such is the report. In many countries a photographic suspect would be unceremoniously "run in," but, according to the telegram, they are more considerate in Spanish territory with regard to foreigners. However, as we have often said before, English photographers, travelling in foreign countries, should be careful where they use their cameras, because the authorities do not always, as it would seem they do in Spain, shadow the tourist, and send daily reports to the authorities, before they subject him to sometimes serious inconvenience.

## DEFECTS IN PLATINOTYPE PRINTS.

SEVERAL correspondents of THE BRITISH JOURNAL OF PHOTOGRAPHY having complained of the difficulty they experience in obtaining good vigorous and rich prints in platinotype, the following notes on the most usual causes of poor weak or "mealy" prints may be of assistance in ascertaining and removing the cause of failure, it being assumed that the paper has been kept thoroughly dry until the time of development, and that the negatives are sufficiently vigorous to give a rich print. Unless these two conditions are fulfilled, it is useless to expect good results.

The most common cause of weak prints, without any richness of tone or force, is that the developer is too cold, and it is noteworthy that two recent correspondents complain that only during the last two or three months have they been troubled with this falling off in the quality of their prints. Whatever strength of solution is used for developing, it should never be colder than about 65°. In many cases a stock solution is kept in a very cold place, and may, in addition, be diluted at time of using with water drawn from a tank so situated that its temperature is always low, and this may be an unsuspected cause of failure to obtain the same quality as similar working had given in the summer time, when the temperature of the air was much higher. Platinotype paper for cold development can be developed at almost any temperature, but from 60° to 90° may be taken as the two extremes for the best results. At 80° or 90°, the strength of solution remaining the same, a print will be more vigorous and also warmer in tone than if developed at 60° or 65°; increasing the temperature above 100° has the effect of making prints muddy and dull, while below 60° the tendency is to give a very cold tone and absence of strength.

Other causes of want of vigour are, first, too weak a developer. Whether the Platinotype Company's "developing salts" or potassium oxalate are used for developing, the most desirable strength for average work is one part stock solution and one part water; the stock solution being either one pound of potassium oxalate dissolved in fifty-four ounces of water, or half a pound of "developing salts" in fifty ounces of water. Diluting these solutions has the effect of giving a warmer tone and lessening the force and vigour of the print, for weak negatives they may be used undiluted.

Second.—Developers kept too long after diluting. The stock solutions will keep indefinitely; when diluted they deteriorate rapidly, especially if used.

Third.—Too many prints developed in a weak solution. Diluted developers should be used for a moderate number of prints only and thrown away after once using.

Fourth.—Developer, whether strong or weak, exposed to strong daylight after using and then used again, the resulting prints are muddy and flat.

If carefully kept from light, either of the stock solutions given may be used again and again, and if made up to the original bulk from time to time with fresh solution of the original strength, will remain in good working order for years. This was the usual method of working with the hot-bath process, but with the cold it has frequently a tendency to give harsh contrasts with rusty or bronzed shadows if solarisation has commenced. This bronzed effect can be always avoided by diluting the developer.

One correspondent complains of streaky markings. These may be caused by immersing the print in a small quantity of solution and allowing it to touch the bottom of the dish during development. There is no objection to immersing the print instead of floating, but it should be taken as little below the surface as possible. Or, another cause may be seen on the developer; this can be avoided by filtering the stock solutions and keeping them corked. Or, air bubbles may form on the print and not be noticed until the remainder of the print is almost developed; it is difficult in such a case to prevent markings. As soon as a print is in contact with the developer it should be raised and any air bubbles broken; any part that has not been in contact with the fluid will develop up and show no markings if the print is immediately immersed again, but not more than three or four seconds should elapse from the time that the print is first brought into contact with the developer and its second immersion.

A most instructive experiment, one that would teach more than volumes of writing, would be to take several prints, or small pieces of prints, and develop them at different temperatures varying from about 50° to 120°, and with strengths of solution ranging from undiluted stock to one part stock with five or six parts water.

Platinotype is a beautiful and exceedingly simple process; but, in order

to secure its full beauty, its capabilities require careful study, and it would appear that in many instances its simplicity prevents its receiving that careful attention to small details that is essential even in the simplest work if success is to be attained.

HENRY W. BENNETT, F.R.P.S.

## FOREIGN NEWS AND NOTES.

**The Action of Ammonium Persulphate.**—M. Hassreidter stated recently before the Association Belge de Photographie that he had found that ammonium persulphate acted quite differently to other reducers, and did not attack the shadow details, but rather the high lights, a fact which has also been noted in England. He further stated that he found that a two and half per cent. was the best strength to use, and that, as the reduction continued during washing, it was advisable to stop the action by immersing the plate in a solution of hyposulphite of soda.

**Photography in Colours.**—Before the Louvain section of the Association Belge de Photographie the process of M. Dugardin, which was briefly referred to last month in our columns, was fully described, and it turns out to be the three-colour process, and the superposition of three carbon positives, which is by no means new; but there is one point of novelty in the process, unless no less than three mistakes are made in the report. Three negatives are obtained by suitable screens and orthochromatic plates; the actual words of the report are: "L'un par les radiations jaunes, l'autre par les bleues, et le troisième par les verts, c'est-à-dire par les trois couleurs fondamentales du spectre." From these negatives bichromated gelatinised papers containing yellow, green, and violet pigments are printed and then superposed. The novel point is the use of yellow-green and violet pigments as reproduction colours. One naturally wonders how red or purple would be formed.

**Encore et Toujours la Photographie des Couleurs.**—We also referred last month to the Mathieu-Dery process, and further details are now given, and it is interesting to note that the description, which, by the bye, was given by M. Mathieu, is a marvel of inconsistencies. In the first place he claims to have made a plate sensitive to red and yellow, and *insensible to blue*, another sensitive to yellow and blue, and insensitive to red; this, judging from the plates our English makers turn out, is not a difficult job, and a third plate sensitive to red and blue but not to yellow; some few would like to know how this is done. He further claims that each of the plates is so prepared as to allow three colours to act which are wanted to act, and that they should not be affected by those which are not wanted to act, and yet he uses light filters to cut out certain colours! The following passage is very hopeful: "J'estime que le temps n'est pas loin où les écrans seront complètement mis de côté, et le triage rigoureux obtenu uniquement par les qualités spéciales des trois émulsions." This hails, we know, from the land of Ducos du Hauron and Cros; but what do some of our plate-makers say to it? The rest of this paper we may dismiss, for the author not only claims to have done what no one else has, and what is generally considered by those who have paid most attention to the subject to be impossible, but he also claims for his process of photography in colours the total abolition of that want of perspective and depth which characterises all monochrome photography.

**The Gum-bichromate Process.**—Herr Watzek points out in the *Photographisches Centralblatt* that it is always advantageous to give the paper used for gum bichromate a preliminary sizing, and he has found that chrome gelatine is the best; and, if plain gelatine is used, the colour mixture is partially and locally absorbed, and the result is that it is difficult to obtain clear high lights, and too often patchiness of the prints results. The particular strength of the chrome gelatine recommended is five per cent. of a five per cent. solution of chrome alum in a five per cent. solution of gelatine, and the mixture must be applied hot. At the suggestion of Herr Ghiglione, he had tried with success the use of decomposed gelatine; a five per cent. solution of gelatine was exposed in an open vessel till it had become mouldy on top and liquid underneath, the liquid portion was poured into a bottle, and, to every 1000 parts, from five to ten parts of formaline added and kept well corked; this can be diluted with water to any extent, and for thin papers should be diluted with about an equal quantity of water, but used full strength for drawing papers.

## ON THE PRODUCTION OF WARM TONES ON BROMIDE PAPER.\*

URANIUM toning has been discussed so copiously in the photographic press of recent years that I do not propose to touch upon it, except in passing. It yields a range of very rich red and brown tones, which, however, are freely soluble in water and of doubtful permanence. The prints must be lightly developed, as the process is one of intensification. The developer should not be ferrous oxalate. They must be thoroughly fixed and thoroughly washed, and chemical contamination in every shape avoided. In order that the solution may act uniformly, the print, if it has been dried, must be first soaked in clean water. If the colour produced is not satisfactory, the print may be restored to its original condition by immersion in a bath of three or four drops of ammonia to a pint of water, and, after further washing, may be again toned. Some improvement results from following the toning by a two per cent. solution of ammonium sulphocyanide, which also helps to get rid of the bichromate stain. Other points to be noted are, that the full force of the water from the tap must not be allowed to fall on the prints, and that they must be blotted off after washing, or some other means adopted to prevent unequal drying.

We next come to the methods of bleaching and subsequent redevelopment, which all yield warm tones. The bleaching agent may be potassium bichromate, ferric chloride, cupric chloride, mercuric chloride, or potassium ferricyanide, and, which ever we may select, it is necessary to add hydrochloric acid. The best is—

Potassium bichromate.....	5 grains.
Hydrochloric acid.....	10 minims.
Water.....	1 ounce.

The well-washed print is immersed in this and thoroughly bleached. It must then be washed to remove the bichromate stain, and it is then ready to be developed. Fifteen grains of Schlippe's salt to the ounce of water produces a Bartolozzi red, and, according to the books, an addition of a few drops of ammonia darkens the colour to a reddish-brown, a result which does not uniformly follow.

An alternative method is to darken the bleached image in a bath of from ten drops to one drachm of ammonium sulphide to twenty ounces of water. This produces tones ranging from a yellowish-red to a dark brown, a vigorous original and a stronger solution of the sulphide yielding the darker shades, and the weaker solution generally tending to produce the less attractive yellowish tones. The bleached image may be developed in the ordinary sense of the term, using any non-staining developer, and this is a capital means of saving a print which is of a bad colour. Probably, by the use of a weak and well-restrained developer and a prior exposure of the bleached print to daylight, a warm-toned image might result, but I have not had time to try this. The image may also be darkened up to full intensity by sunlight, but it takes three or four days' exposure, and the print must, in the first instance, be very vigorous and the bleaching action must be thorough. This method produces a very agreeable colour, very suitable for "misty morning" effects.

The bleaching bath may consist, as I said before, of ferric, cupric, or mercuric chlorides. As these possess no advantage over the bichromate of potash, and, on the other hand, the presence of the metal is a complication which renders it very difficult to avoid stains, and as they yield much the same tones as the bichromate method, there is nothing to recommend their use.

Whilst discussing these processes it may be remarked that the silver chloride image formed by the cupric and ferric salts may be darkened by exposure to sunlight—of course, after the copper or iron has been eliminated by the use of a weak solution of hydrochloric acid and copious washing—and the results are scarcely to be distinguished from those produced by the bichromate method. It may also be noted, with regard to the latter process, that the chromic stain may be removed very quickly and the washing much shortened by the use of a weak solution of sodium sulphite. In addition to the above bleaching agents, chlorinated soda, chlorine water, and others have been proposed; but, as their action is merely to convert the image into one of silver chloride, and as the final tone of the print is decided by its original density and the after-treatment bestowed upon it, the simplest means of producing the chloride of silver image should be selected, and this is to be found in the bichromate method.

Mercuric chloride as a bleaching agent is in some respects different to the others. The image does not darken appreciably by exposure to light, and it may be developed up to full intensity by the use of a combined fixing and toning bath, weak in hypo and strong in gold. Very good tones are produced, but mercury is not a desirable element in a photographic image, and the process is therefore better left alone.

A process recently recommended is to bleach in a five per cent. solution of potassium ferricyanide to which is added about one-tenth of its volume of hydrochloric acid (this seems unduly strong in acid). After washing, the print is developed in a weak and well-restrained developer. This is said to produce warm tones, but I have not had any opportunity of testing it.

\* Concluded from page 58.

Bromide prints may also be bleached by an aqueous solution of iodine and iodide of potassium of a dark cherry colour, and afterwards darkened by either a solution of Schlippe's salt or ammonium sulphite, the former producing reddish tones and the latter very fine browns.

This is a method which I can confidently recommend, as it is easily worked and the results are very satisfactory. In any formula involving the use of iodine the print is instantly stained a deep blue, due presumably to a combination between the iodine and the starch sizing of the paper, iodide of starch being formed. Washing in running water for half an hour, followed by a few hours' soaking, will get rid of the most obstinate case of this stain; but, by the use of a weak solution of sodium sulphite, to which a drop or two of hydrochloric acid is added, it is quickly decomposed, and a much shorter washing will then suffice. In no case, however, should the washing be hurried over, as stains may appear on the application of the sulphite solution.

Before passing from this subject, I may remark that the results produced by these various processes of bleaching and subsequent redevelopment show signs of considerable permanence. Some have been subjected to the action of a strong clearing solution of thiocarbamide, alum, and hydrochloric acid, for twenty-four hours without the slightest reduction of density, alteration of colour, or loss of detail; others have shown considerable resistance to the action of reducers, and others have been exposed to light for twelve months without any appreciable change.

The production of warm-toned prints by simple development may well form the subject of a separate paper. Some tentative experiments have been made, using various lantern-slide formulæ, with pyro as the principal agent, and I have also tried pyro-acetone, but the results have tended more to greenish-yellows than to sepia and browns. This is just as might have been expected. A formula which will yield a rich sepia in the lantern slide will almost inevitably, in the case of a paper print, produce a nondescript colour of a yellowish tint. This difference is to be accounted for by the fact that, in the one case, we are dealing with transmitted light, and, in the other, the light is reflected. Ortol and ammonia and a partly oxidised amidol developer have been recently proposed as likely to give considerable richness of tone, and I remember having produced very satisfactory prints of a brown shade some years ago by the use of eikonogen; but, beyond the fact that the production of the desired tone was very uncertain, no details remain in my memory.

And now I leave the subject, with the consciousness that I have only touched its fringe, and that it may well supply an experimentalist with a solid twelve months' work.

J. BROWN.

## LOCAL REDUCTION OF DENSITY.

We frequently find, on examining a negative, that some part, it may be large or small, would be better if rather less dense, though the rest of the plate may be right, and those who have had long experience have generally become acquainted with satisfactory means of reducing those parts, and so balancing the general effect of light and shade; but some there may be who have not yet made this a study, and their work therefore lacks that degree of refinement which others possess.

Such effects are often brought about by patches of sunlight which come through trees on an outdoor group, or some article of dress in a portrait which is too light for its position, or a flower worn in the hair may destroy the effect of light on the face. In outdoor work a gable end may receive strong sunlight, and spoil the harmony, and with an interior there may be a patch of sunlight coming through a window—or a window in the picture may be too light and require to be subdued.

It is to obviate these troubles that remedies are sought, and, fortunately for modern photography, the gelatine plate or film lends itself to various plans which in the old collodion process would have been impossible.

We will deal first with very small spots, as these are comparatively simple. To reduce small spots the plate must be quite dry, and the point of a lancet used either as a scraper or to pick the spot out; if the plate is moistened in a slight degree by the breath of the operator, too large a part may be moved in scraping. If the spot is to be reduced only slightly, it is best done by making a solution thus:—

Water .....	1 oz.
Perchloride of iron .....	$\frac{1}{2}$ "
Hydrochloric acid .....	$\frac{1}{4}$ "

Apply this with a small brush and allow a drop to cover the spot for a few seconds, then apply a few drops of the ordinary fixing bath, or put the plate into the fixing and wash well afterwards. This plan done carefully will reduce a spot very neatly and evenly.

Another easy plan with small spots or markings is to cut the end of an old spotting-brush handle to a point, and, having dipped it in methylated spirit, rub it with some firmness on the spot, and then wipe off with a rag; continue this process till enough has been removed.

When we have larger parts to treat, there are several ways of doing it. Methylated spirit rubbed over the surface with a rag, pressing firmly on the part to be reduced, is, perhaps, the easiest plan and the safest, as the effect is so easily watched, and the plate requires no treatment after the spirit, as it does after the perchloride; but it is more suited to hard edges, as, for instance, making a distant sea line show, which can easily be done

if a piece of note paper is held to the line, and the spirit applied with the rag by being rubbed hard along the top.

For the shadows under clouds, or for reducing white pillars in a church, the spirit is excellent; but, for the general reduction of the whole foreground or one side of a negative, the best plan is to wet it thoroughly, and, while still very wet, flood that part to be reduced with the perchloride of iron solution above mentioned, diluted with about five times its bulk of water, as it would be much too strong as it is; this changes some of the reduced silver in the plate into chloride of silver, which must then be dissolved away by putting the plate in the fixing bath for two or three minutes. It will then be seen how far it has been reduced, and if it is not sufficient, it must be washed well and the perchloride again applied.

There are several other solutions for this purpose, but none are so simple and certain as this. The object of wetting the plate is to prevent a hard line being formed, and to cause the solution to act evenly. Of course, care will have to be used to prevent it from running where it is not required, by slightly inclining the plate. This plan will often cause clouds to become printable, when the density of the sky had previously obscured them.

If a plate has been over-exposed, and it is found difficult to get sufficient density in the sky without over-developing the scenery, it is a good plan to continue the developing till the sky is dense enough, and then, after fixing and washing, reduce the scenery in daylight till it is thin enough to print properly, leaving the sky alone.

ALFRED SEELEY.

### ARCHITECTURAL PHOTOGRAPHY.

Before the Gospel Oak Photographic Society, on Tuesday, January 17, Mr. C. Stone delivered a lecture on "Architectural Photography." In opening, the lecturer showed how well the study of architectural photography combined with the pursuit of other hobbies. The student of sculpture would find much to engross his attention in the decoration of our large cathedrals and churches. The lover of carving could gratify his passion, and the musical and historical enthusiast would be interested in the fine old organs, and the records which were to be found in the ecclesiastical archives, and the pictures and adornments of the fabrics themselves.

Architectural photography, to be really successful, must be made a speciality of by him who undertakes it, but the care, patience, and time expended upon its study and practice would be amply repaid by the results. A young friend of his, who had become the proud possessor of a hand camera, was advised to make his initial exposures on architectural subjects because "they did not move." Now, of all things in the (photographic) world, the hand camera was the least suited to the class of work with which he was dealing. The most suitable camera, and the one he would advise if one were dealing with architecture alone, was the square bellows pattern. This was a trifle heavier than the form with taper bellows, and, should the latter be selected, care should be taken to see that the taper of the bellows was not too sharp, otherwise some portion of the image might be cut off when using short-focus lenses. The camera should be fitted with all the usual movements, such as rising, falling, and cross fronts, and, most important of all, a swing back with plenty of play, as when one wished to secure pictures in which the ceiling was introduced, it often became necessary to tilt the camera pretty considerably, and to compensate for this tilting, and to prevent distortion of the image, the back would often have to be swung considerably. Levels—circular ones were preferable—should be affixed to the camera, and one should find a place on the swing back to indicate when the plate was accurately vertical.

Distortion was the *bête noir* of the architectural photographer. In most branches a slight amount would not be apparent, but the large number of parallel lines in the frames of windows, rafters of ceilings, &c., would necessitate the greatest care to prevent a grotesque result. This reason alone would put the single lens out of court, and only such lenses as give rectilinear images should be chosen. For ordinary work a lens of average focal length will be sufficient, say five or five and a half inches for a quarter plate, but in confined situations a shorter focus, or what is called a wide-angle lens, must be employed. This latter instrument should, however, be used very sparingly, and only on occasions when the longer-focus lens prevents sufficient of the image being obtained, as it is apt to give a bad perspective.

As regards the stand, this should be as high as possible, and of the most rigid pattern procurable, as the long exposures necessary gave many opportunities for vibration.

The best plates for general use were isochromatic ones, of what is usually called "ordinary" rapidity, and these, for the prevention of halation, should be backed. The lecturer stated that he had tried backing papers for the prevention of halation, but they were not successful, owing to the difficulty of getting optical contact; but a backing medium, put up in collapsible tubes, which was now on the market, seemed to be efficacious, and, moreover, was very cheap.

Despite all attempts to prevent it, halation would occasionally make itself manifest, and the best way of removing it was by rubbing down the negative with methylated spirits, applied on a piece of wash-leather in which the tip of the finger was wrapped. Considerable force would have

to be used in this rubbing, but no fear need be felt of damaging the negative, providing it was perfectly dry before commencing operations upon it. The negative should be laid on a level surface, however, otherwise there was a danger of cracking it.

Coming to the actual subjects themselves, one would always do well in writing to the authorities for permission to photograph, more especially in the case of interiors. A politely worded letter seldom met with a refusal; in fact, the lecturer said, he had never been refused but once, and in this case the interior of a country church was the subject, the reason given was that it was against the interests of the local photographers to permit views to be taken of the edifice. There was not much in the objection, however, more especially in the light of some of the commercial views he had seen. In some places a charge was made for admission, in others a charge was made both for admission and for permission to photograph; but in the majority of instances no charge was made at all, and usually everything is done to enable the photographer to pursue his hobby in comfort. It was a very good plan to make friends with the head verger before commencing operations, as that gentleman was often able to point out objects which might otherwise pass unnoticed.

Excellent results could sometimes be obtained by photographing a cross the nave of a church or cathedral instead of straight up the centre aisle, and attention should be paid to the peculiar carvings which were sometimes to be found at the ends of the choir stalls. The chancel was generally a difficult subject, owing to the large amount of stained glass which was to be found at the back of the altar. A dull day should be chosen for the photography of stained glass windows, and a backed isochromatic plate, with a screen, should be employed. The colour of the screen would, of course, vary with the character of the subject. For one containing much red and blue a rather dark one was best, such as to necessitate the exposure being increased four or five times, being about right.

### BURNETT'S COMBINED MUSIC AND CAMERA STAND.

MR. BURNETT'S invention relates to a new or improved combined music and camera stand, the object being to construct the stand so that it may be used either as a music stand or as a camera stand. In carrying out his invention he forms the legs of the stand of suitable material, and which are connected together at the upper ends by means of a socket piece. The legs are so arranged that they may be folded together, and a cap or cover screwed upon the top socket so as to maintain them in their folded position, when the whole may be used as a walking stick. Suitable stay rods are provided for giving rigidity to the legs when extended. The music-holder or stand is formed of strips or sections, which are pivoted

together so that it may be folded or collapsed when not in use, the music stand being provided with a socket piece which fits in the socket aforesaid when required. When desired, a camera may be carried upon the socket.

Fig. 1 is a view showing the invention in use as a music stand.

Fig. 2, side elevation of the same when folded up for use as a walking stick.

Fig. 3, vertical section to enlarged scale on top of the stand.

*b* is a music stand composed of strips and pivoted together, and adapted to be folded or collapsed when required. *c* are the legs of the stand, which are pivotally secured to the socket piece, *f*, being provided when required with the struts or supports, *d*. The socket piece, *f*,

carries the sliding rod, *a*, which may carry the music stand or camera, being secured in position in the socket, *f*<sup>1</sup>, by means of the set screw, *f*, or the like. When the legs, *c*, are folded together, and the cap, *e*, placed in position by engaging with the socket piece, *f*<sup>1</sup>, they are prevented from expanding or opening, and the whole may then be used as a walking stick.

If desired, the cap, *e*, may screw on to the rod, *a*.

### ESTIMATION OF GELATINE.

[From *Comptes Rendus*.]

THE insolubilisation of gelatine by means of formaldehyde soon suggested itself to chemists as a means of quantitatively estimating gelatine in food stuffs and other commercial products, and methods which make use of this reagent, have been published. In a recent communication to the Paris Academy of Sciences, M. A. Trillat describes the practical use of formaldehyde for this purpose, and, as his paper may prove useful to photographic experimentalists, we give it as it appears in the *Comptes Rendus* for November 7:—

"Dissolve the substance in water, and separate any insoluble matter by filtration or decantation. Evaporate the liquid to a syrupy consistency; add about 1 c. c. (17 minims) of commercial formic aldehyde, and continue the evaporation till the whole is pasty. Take up the residue in boiling water, which dissolves those substances unaffected by formaldehyde. The presence of gelatine is indicated by the presence of a loam-like deposit of insoluble gelatine. Before weighing this it is necessary to remove all soluble matters mechanically retained within its pores. To filter and wash is very tedious; it is best to decant the liquid. The precipitate settles completely in twenty-four hours, or, at any rate, merely leaves the liquid slightly opalescent. The insoluble gelatine is broken up and washed with boiling water until the washings contain none of the products associated with the gelatine, as indicated by suitable tests. The precipitate is then dried over a salt bath and weighed. Two examples of the accuracy of the process are here appended:—

"A mixture was made containing 35 parts of gelatine, 20 parts of gum, and 10 parts sugar. This mixture (65 grammes) was dissolved in 500 c. c. of water and 50 c. c. of the solution used for the estimation. The gelatine estimation was made within one per cent.

"A second mixture of gum (35 grammes), gelatine (5 grammes), and sugar (5 grammes) was prepared, the gelatine in which gave a figure differing from the theoretical result by only 0.5 per cent. The method is thus accurate enough for most cases. The presence of sugar does not affect the results. The increase in weight of the gelatine by combining with the formic aldehyde is quite negligible, as the latter passes almost entirely into the washings, a dissociation due to the great difference in molecular weight between albuminoid matter and formic aldehyde.

"In order to estimate gelatine in the presence of albumen or other substances coagulated by heat, these bodies must be first separated by boiling. In all cases it is better to add the formaldehyde to the substance in a pasty condition, as no precipitate separates from the dilute solutions. Albuminoid substances which have been rendered insoluble by formaldehyde are not attacked by alkalies or dilute acids, they are completely insoluble in boiling water, alcohol, ether, and neutral liquids."

### THE PHOTO-CHEMICAL ACTION OF TURPENTINE.

[From *Chemiker Zeitung*, 1898, No. 90.]

THE interesting experiments of Becquerel on the action of various substances on the photographic plate have been continued by Russell,<sup>†</sup> who has found that oil of turpentine has a strong action on photographic plates. Arguing from his experiments, Russell inclines towards the view, put forward by Stokes, that vapours of these chemically or photo-chemically active bodies are the cause of the darkening of photographic plates. From the first this explanation has not struck me as fitting in with the facts, for two reasons: (1) Because oil of turpentine, when acting on metallic haloids, separates from them not the metal but the halogen, with absorption of metal, whilst in the case of the photographic plate the metal is separated; (2) the photo-chemical action of turpentine takes place through media which are difficultly penetrable by turpentine vapour.

In order to decide whether the results of turpentine on photographic plates were due to chemically active vapour or to chemically active rays, I repeated Russell's experiments, selecting the oil which he states to be most active.

I had constructed a three-storied rectangular frame of pieces of wood 13 mm. (= 5½ inches, about) in length, 10 mm. (= ¾ of an inch) broad, and 8 mm. (= ⅜ inch) thick. The height of the frame was 80 mm. (3 inches), its breadth 90 mm. (3½ inches), and its length 134 mm. (5¼ inches). In each story a photographic plate was placed, and on the middle plate an open porcelain basin containing turpentine. The frame was placed on a plate of glass (ground matt), and covered with a

small glass shade, so that the turpentine and the plates were together in a confined space, which was of necessity saturated with turpentine vapour. The apparatus was set up and kept in a dark room, the plates being exposed to the action of the oil for from four to five days.

**Experiment 1.**—The plates were laid film up on the first and second stories, and film down on the third. After exposure all the plates were strongly darkened, but the middle one was transparent on and immediately around the place where the porcelain basin had stood.

**Experiment 2** was arranged as the first, except that the film side of each plate was reversed in position (turned over). After a similar exposure all the plates were blackened at the edges, but otherwise transparent. In both experiments the space in which the plates were exposed was saturated with turpentine vapour, so that all parts of the sensitive films were exposed to its action. If the blackening were the result of the action of a vapour, the plates in each experiment should have been completely blackened; but, as stated above, this was not the case. If, however, the blackening be assumed to be due to the radiation of the turpentine, the results of each experiment become explicable. According to my view, turpentine gives out particularly active photo-chemical rays, which fall directly on to the plates on the third story, as well as on the inner surfaces of the glass, and are then reflected to the other plates. In the first experiment every portion, and in the second only the marginal portions, of the plate could be struck by the reflected rays. The question arises, Upon what does this property of turpentine to emit radiation depend? The answer is not far to seek. The cosmic ether fills not only empty (planetary) space, but also the intermolecular spaces of every body. The ether in a body is not in a state of rigid equilibrium, but there is a constant exchange going on between the ether of the body and the ether in its neighbourhood. The only sense in which there is equilibrium is that a body receives in a given time as much ether as it loses. The molecules of a body affect the density, elasticity, and oscillations of the ether in their neighbourhood. The ether which surrounds the molecules of turpentine, and which is emitted by the turpentine, makes oscillations under the influence of the turpentine molecule which are similar to the oscillations of ultra-violet rays, and, like them, chemically active. I will return to this question later.

DR. JOACHIM SPERBER.

### WIGHT'S APPARATUS FOR DEVELOPING, FIXING, AND WASHING PHOTOGRAPHIC FILMS.

THE principal object of Mr. Wight's invention is to treat photographic films without handling them or exposing them to the light, and without the necessity of using a dark room, but it is also useful for avoiding handling in a dark room.

The apparatus consists of a box divided into two compartments by a movable partition, each compartment being provided with a door. The upper compartment contains a drum or reel, and the lower compartment has a false bottom free to rise and fall, being mounted as a parallel ruler, or in other like way.

The mechanism for removing the partition, turning the reel, and raising and lowering the false bottom is so arranged that it can be operated from the outside without admitting light.

In using the apparatus for treating a flexible film the doors are opened, and the end of the film to be treated is drawn into the upper compartment through a slit and fixed to the reel.

The upper door is shut and the reel turned, drawing in the film through the slit. When the desired length has been wound on the reel, it is automatically secured and separated from the remainder by a knife working inside the box and operated from the outside. A tray containing the proper solution or liquid is placed on the false bottom, the lower door is shut, and the partition removed. The false bottom is then raised until the solution in the tray comes up to film on the reel. The reel is then turned so as to bring all the film in turn into contact with the solution for a sufficient time. When it is desired to change the solution, the false bottom is lowered, the partition is replaced, and the tray removed through the lower door.

Figs. 1 and 2 are vertical central sections at right angles to each other. Fig. 3 is a section on the line 3—3 (fig. 2), the case, *m*, and reel being omitted.

Figs. 4 are central sections at right angles to each other of the printing case, *o*.

Fig. 5 shows a stand for the reel.

*a* is a box provided with two doors, *a*<sup>1</sup>, *a*<sup>2</sup>, and divided into two by a sliding partition; *b* is a shaft having one end working in a bearing, *a*<sup>3</sup>, in the side of the case, and the other end in a bearing, *d*<sup>1</sup>, at the end of a spindle, *d*, working in a sleeve, *a*<sup>4</sup>, projecting inwards from the door, *a*<sup>1</sup>. The spindle, *d*, is normally pressed inwards by the spring, *d*<sup>2</sup>, keeping the bearing, *d*<sup>1</sup>, in contact with the shaft, *c*, but it can be pulled a short distance outwards to disengage it, and held in that position by causing the pin, *d*<sup>3</sup>, to enter the bayonet joint slot, *a*<sup>5</sup>, in the sleeve, *a*<sup>4</sup>. *e* is a sleeve fitting on the shaft, *c*, and revolving with it by reason of a pin, *c*<sup>1</sup>, carried by the shaft entering a notch in a flange on the sleeve. *c*<sup>2</sup> is a nut screwing on the shaft and holding the sleeve in place. The sleeve, *e*, has fixed to it a disc, *c*<sup>1</sup>, carrying bars, *c*<sup>2</sup>, whose other ends are connected by an annular plate, *c*<sup>3</sup>, the whole forming a reel. By unscrewing the

\* THE BRITISH JOURNAL OF PHOTOGRAPHY, 1895, p. 214.

† *ibid.*, 1898, p. 213.

nut,  $c^2$ , the reel can readily be removed, and the width of the box is such that wider reels than that shown can be employed to receive wider films.  $c^2$  is a worm wheel fixed to the shaft,  $c$ , and gearing with a worm,  $f$ , on a

wards, the other round the roller and backwards. The lid,  $m^1$ , is then put on and the case inserted into the hole in the box,  $a$ , the parts being in the positions shown in fig. 2. The door,  $a^1$ , is opened, and the reel is

Fig. 1.

Fig. 2.

shaft,  $f^1$ , turned by a handle,  $f^2$ , outside the box.  $g$  is a false bottom mounted on parallel links,  $g^1$ , and raised and lowered by a roller,  $h$ , bearing on its under side. The roller,  $h$ , is carried by an arm,  $h^1$ , fixed to a shaft,  $h^2$ , turned by a handle,  $h^3$ , outside the box. When raised, the arm,  $h$ , is turned slightly beyond the vertical, and rests on a stop, so remaining in that position until the handle,  $h^3$ , is turned back again. In fig. 1 the false bottom,  $g$ , is shown raised, and in fig. 2 lowered.  $j$  is a mirror fixed to the door,  $a^1$ , and going inside the reel.  $j^1 j^1$  are sight holes glazed with non-actinic glass, through which the film can be inspected either directly or by reflection. The holes,  $j^1$ , can be closed by shutters,  $j^2$ .  $k$  is a bath having a dovetailed foot,  $k^1$ , fitting in guides,  $g^2$ , on the false bottom,  $g$ .  $e^4$  is a bar having its ends fixed to the disc,  $e^1$ , and annular plates,  $e^3$ . If it is intended to treat short lengths of films, several such bars are provided in suitable places, or the bar may be movable.  $l$  are a pair of jaws pivoted to and normally pressed down on to the plate,  $e^5$  (fixed to  $e^1$  and  $e^3$ ), by the spring,  $l^1$ .  $l^2$  is a lever pivoted to the plate,  $e^5$ , which, when the parts are in the position shown, comes above the tail end of the jaws,  $l$ , and holds the jaws off the plate,  $e^5$ .  $m$  is a case and  $m^1$  its lid. This case fits into a hole in a box,  $a$ , being prevented from entering too far by the ridges,  $m^2$ . The case,  $m$ , receives a frame,  $m^3$ , carrying a roller,  $m^4$ , and bearings for a spool,  $n$ , on which is wound the film,  $n^1$ , and black paper,  $n^2$  (technically known as a cartridge).  $m^5$  is a spring arm bearing on the cartridge and preventing it from accidentally unwinding.  $m^6$  is a roller at the front of the case,  $m$ . The case,  $m$ , might be dispensed with, pivots for the cartridges being provided inside the box,  $a$ , but this arrangement is not so convenient.  $o$  (fig. 4) is a somewhat similar case fitting the same hole in the box,  $a$ , and containing a spool,  $c^1$ , of sensitive paper or film, a printing frame,  $c^2$ , and a slide,  $c^3$ . At its front end is a roller,  $c^4$ .  $p$  is a knife working in guides,  $a^6$ , in the box,  $a$  (these are omitted in fig. 1), and  $m^7 c^5$  in the cases  $m$  and  $o$ ; it is operated by a handle,  $p^1$ , from the outside of the box,  $a$ .  $a^7$  are flaps or guards to receive drips and return them into the bath.

All the openings into the box,  $a$ , and cases,  $m$  and  $o$ , are rendered light-tight in well-known ways.

When employing the apparatus for developing a cartridge film which has been exposed in a camera in the ordinary way, the procedure is as follows:—

The cartridge,  $n$ , containing the exposed film, is taken from the camera and placed in the case,  $m$ . A short length of the film,  $n^1$ , and of the black paper,  $n^2$ , are unwound, the one being led under the roller,  $m^4$ , and for-

wards, the other round the roller and backwards. The lid,  $m^1$ , is then put on and the case inserted into the hole in the box,  $a$ , the parts being in the positions shown in fig. 2. The door,  $a^1$ , is opened, and the reel is turned by the handle,  $f^2$ , to bring the bar,  $e^4$ , close to the end of the film,  $n^1$ , which projects into the box. The film is then clipped or attached in any convenient way to the bar,  $e^4$ , and the door,  $a^1$ , is shut. The reel is then turned in the direction of the arrow (fig. 2), winding the film on to it, the corresponding length of black paper being simultaneously drawn out of the rear of the case,  $m$ .

Or the cartridge box may be provided with a receiving roller to take the backing paper, which roller may either be operated by hand from outside the box or automatically; in such case the slit for the backing paper is not required, as the paper does not pass outside the box.

After a time the flange,  $e^4$ , of the plate,  $e^5$ , comes against the roller,  $m^4$ , and prevents the further movement of the reel, and simultaneously the projection,  $l^2$ , on the lever,  $l^2$ , comes against the stop,  $a^3$  (fig. 3), on the door,  $a^1$ , and the lever is turned freeing the jaws,  $l$ , which are then caused by their spring to hold the film against the plate,  $e^5$ . The knife,  $p$ , is then forced down, cutting off the length of film which remains fastened on the reel. The knife is raised and the case,  $m$ , slightly withdrawn so as to allow the reel to turn, but not sufficiently to admit light. A bath,  $k$ , containing a suitable developing solution, is next put into place on the false bottom,  $g$ , the door,  $a^1$ , is closed, the partition,  $b$ , withdrawn, and the false bottom,  $g$ , raised. The reel is then turned by the handle,  $f^2$ , until the whole of the film has been sufficiently treated. The bottom,  $g$ , is then lowered, the partition,  $b$ ,

put in, the door,  $a^1$ , opened, and the developing solution replaced by a fixing or other solution or water. The same operations are repeated and so on until the treatment of the film is complete. The door,  $a^1$ , is then opened, the nut,  $c^2$ , unscrewed, and the reel with the film on it removed.

Fig. 5.

Fig. 3.

Fig. 4.

A spindle,  $q$ , is passed through the sleeve,  $e$ , and the reel, mounted on the stand,  $r$  (fig. 5), is put under a stream of water, which causes it to revolve, and thoroughly washes the film.

In using the apparatus for printing the procedure is very similar: The end of the sensitive paper is led from the bobbin, *a*<sup>1</sup> (figs. 4), through the slots, *a*<sup>2</sup>, *a*<sup>3</sup>, into the box, *a* (which is laid on its back), its end being attached to the reel as above described. The frame, *a*<sup>4</sup>, containing the negative, *a*<sup>5</sup>, is put into place, the slide, *a*<sup>6</sup>, is withdrawn, and the frame pressed home to bring the surface of the negative into contact with the film, and the shutter, *a*<sup>7</sup>, of the frame is opened. After a sufficient exposure the shutter, *a*<sup>8</sup>, is closed, the frame, *a*<sup>9</sup>, is pulled out sufficiently to allow the paper to be drawn through, but not sufficiently to allow light to enter, the reel is turned a short distance and the frame pressed home again. A second exposure is then taken, and so on, until the reel is stopped by *a*<sup>10</sup>. The knife, *p*, is then forced down, cutting off the paper, the length on the reel being treated in a similar manner to that above described. On putting in the slide, *a*<sup>11</sup>, the frame, *a*<sup>12</sup>, may be removed and the negative changed before the whole length of film has been drawn in.

Pointers, *s*, may be provided, capable of being clamped by a nut, *s*<sup>1</sup>, to the spindle, *d*, so that they turn with the reel. These pointers can be set to indicate the position of any parts of the film requiring special treatment, and also to indicate the amount to be wound on after each exposure in the printing frame.

If a dark room be employed, the reel is placed on the stand, *r* (fig. 5), a handle being fitted to the spindle, and the film or paper, as the case may be, attached to it, the necessary baths being placed in succession under the stand. In this way the photograph may be manipulated without any handling.

### PRINTING, TONING, AND FIXING.

As far as the general public are concerned, the above are the most important of the different manipulations in photography with silver printing (as it is usually called, or, more properly, printing out in silver, for bromide is also silver printing), as it is only with the finished print that the sitter is acquainted. This is the part where the skill, or want of it, possessed by the operator comes in, as, given the same negative, paper, toning bath, and hypo, two different workers will turn out a like number of dissimilar results, and a bad worker will get a bad result, even with the best materials.

Judging by the number of queries in the photographic papers, these are (to many) operations of extreme difficulty. No hard-and-fast rules can be laid down, as tastes in photos differ so widely in tone, finish, &c., but the following general remarks, may be found useful.

The first item to consider is the printing-out paper, and it is rather an important one, as, each of the three kinds of paper requires a slightly different treatment though not a great deal, and a little attention to the details mentioned below, will give the highest class results with least trouble and uncertainty.

As albumenised paper was most generally used until the last few years, we will take that kind first. Although the results upon it are not to be compared with the results upon emulsion papers, it is still very largely used, as it stands rough and careless handling better than the finer sorts of paper. One very great objection to it is its liability to fade; and its unreliability is illustrated by the fact that several prints out of one batch will prove almost permanent, while others, done at the same time and under the same conditions, fade very quickly. I have been told by the advocates of albumen that this is the result of careless work, and, if so, should feel inclined to believe that almost all workers in albumen were careless, as nearly all batches of albumen prints suffer from the same complaint, this, to start with, is a very hard thing to believe, as many photographers are careful and conscientious workers; but, beyond that, I know some photographs which were produced by careful men, and still some have faded, while others have kept beautifully—and the best of albumen prints, if exposed to sunlight, fade very quickly.

I have heard some photographers say: "I should like to use the emulsion papers, as one gets so much better results; but, as I have to put 300 or 400 prints into the bath at once, I am afraid they would be spoiled." Well, I am not afraid—I am certain they would, as a great many of the albumen ones are. Some photographers allow their assistants a very large percentage as "wasters," and surely it must be much better, and quicker in the end, to turn out almost the whole of the prints as good ones than have to allow a large percentage of waste, merely by doing a smaller number at a time, for any one with a knowledge of the scientific part of photography knows that it is practically impossible to manage several hundred prints successfully at once with even the most remote hope of permanency or reliability. But, even granting that it is possible or necessary with albumen, there is no need to do so with the emulsion papers, as the various operations proceed so much more quickly than with albumen, which requires to be so deeply over-printed to allow for the subsequent loss. It is probable that having to form the chloride in the pores of the paper itself causes albumenised paper to take longer in the working.

Gelatino-chloride, or P.O.P., as it is generally known in the trade, has taken a very large lead in recent years, and, although not quite an ideal paper, has many advantages over albumen, as it prints, tones, fixes, and washes much quicker, and, though it reduces somewhat, not to anything

like the same extent as albumen, in addition, the prints are very vigorous, with much more detail; and a great advantage with many, especially amateurs, is the ease with which they may be glazed by squeegeeing down if the glass or ferrotype plate is properly cleaned, and French-chalked or waxed; and, although this is supposed by some people to be an "inartistic gloss," it gives the print an effect which is unattainable with any other paper, and, in spite of its defects (mostly in hot weather) I am not at all surprised that it has become so popular, for, if properly worked, it should prove more stable than albumen.

Collodio-chloride, which, although invented so far back as 1865 by the late Mr. G. Wharton Simpson, and sometimes called after him Simpson-type, has (chiefly by reason of the difficulties attending its manufacture) only come to the front during the last few years, approaches more nearly to perfection than any other printing-out paper at present in existence, as the working of it is not affected by the weather, the general results are better, the whites are purer, detail is much greater, it tones with very much less gold than the others, and, even when exposed to strong sunlight, is practically permanent.

The emulsion papers require slightly more care in manipulating than albumen, but this is amply repaid by the time saved in working; dirty fingers and dishes are the great enemies of emulsion papers, as it stands to reason that, the more sensitive the paper and the better the result, the more likely it is to be affected by dirt, and surely no photographer can find a reasonable excuse for either material or chemical dirt. Regarding the operation of printing, unless the negative is a good one, the final print can never be good; this is a point which is often overlooked, the paper and chemicals are blamed, where really the negative is at fault. In one case under my own notice, a complaint was made of inability to obtain pure whites, and of course the paper was blamed. I asked to look at the negative, and found it so thin, that it was actually printing where the high lights should have been; this thinness is often caused by the idea of being able to print so much quicker. To a certain extent this result is attained, but there is a limit which must not be exceeded. Good results are obtained by paying a little attention to the light, in printing, according to the negative, dense negatives printing best in the sun, while thin negatives come out better in the shade.

In printing, each of the above papers requires a slightly different treatment. Albumen requires to be deeply over-printed, with a decided tinge in the high lights, as it reduces so much in the subsequent operations; gelatino-chloride does not require to be printed quite so deeply, the high lights being only faintly tinged, while collodio-chloride should only be printed slightly deeper than the finished print is required, as it should lose very little in toning and fixing if the baths are in proper order.

A very common cause of failure is insufficient washing before toning; this is especially the case with the sulphocyanide bath, which is now almost entirely used for the emulsion papers.

The reason for the use of the salt bath (which is often recommended) does not seem to be understood very well, its use being where paper has not been sufficiently washed, to eliminate the free acids and silver which are nearly always present in these papers. The salt combines with the silver, forming silver chloride, which, of course, does not affect the toning bath, and is easily removed in fixing. The salt bath also tends to give a redder tone to the prints.

The toning bath should be tested for acidity, as very often commercial chloride of gold, and the acetates, tungstates, phosphates, sulphocyanides, &c., which are used as chloride absorbents, are very acid, and an acid toning bath causes a great reduction in the prints, especially with collodio-chloride. It is advisable to add a small quantity of bicarbonate of soda to the toning bath to neutralise it, more especially if, as is very often the case, the paper is insufficiently washed, to also neutralise the free acids, which otherwise would strongly acidify the bath. It may be thought too much trouble to see that the toning bath is not acid; therefore I would ask any one who thinks so to try and tone with a bath made purposely acid, place a print in, and note the great loss of density, probably spoiling it; then make the bath alkaline, place another print in, and observe the difference. I am quite sure that sensible photographers will not think it too much trouble again, as they will be able to trace the cause of many spoiled prints, should they not have already found the reason of this trouble. The time and trouble may be reduced to a minimum as follows: Most photographers, I presume, usually work with a standard-quantity bath, and if the amount of bicarbonate necessary to neutralise the average bath is once found, and a small measure (a spoon will do), holding the required quantity, is kept, all that would be required is to fill the measure with bicarbonate and empty it into the bath; not a great deal of trouble where it means the saving of prints.

Sometimes complaints are made of double toning with gelatino-chloride; this usually occurs from using a gold bath too strong, and the gold is deposited too rapidly and unevenly. Strong baths with gelatino-chloride have the advantage of toning quickly, but, as it is often at the expense of some of the prints, it is difficult to see where the advantage comes in.

The toning bath for collodio-chloride should never be very strong in gold, or great reduction in depth takes place, with poor, blue tones. I recommended an amateur to try collodio-chloride some time ago. He said he did not understand it, and asked how it was worked. I told him, the

same as working gelatino-chloride, only not to use too strong a toning bath. He said he always liked to use a strong one, which I told him was useless for collodio-chloride; however, he insisted upon using a strong bath, with, of course, the usual results of no density and blue tones, and, to make matters worse, kept adding gold, thinking to get the tone he required, where, in fact, he was getting farther away from it. He was very much disgusted with the result, which, of course, he put down to the paper, though it was entirely due to his own stupidity, for it is a well-recognised fact that collodio-chloride must *not* be toned in a strong bath.

In toning, gold deposited quickly gives blue tones, while that deposited slowly gives red ones.

The combined toning and fixing bath is an abomination which no photographer with any care for his work should tolerate, as, no matter how carefully it is worked, there is no certainty of knowing how much gold the bath contains, or if it contains any at all, as the sulphur in it will tone after all the gold is used. Fancy a combined bath made with a mixture of alum and h. po., as occasionally recommended, the chemical formulae for which are, respectively,  $\text{Al}_2\text{K}_2\text{ISO}_4 + 24\text{H}_2\text{O}$ , and  $2\text{Na}_2\text{S}_2\text{O}_3$ . What a grand chance of sulphur toning, and how would it stand for permanency? Always use distilled water in making up toning baths, it is a little more expensive to start with, but in the end is cheaper, when the spoilt prints and lost time and gold are taken into consideration.

In hot weather it is usually recommended to use an alum bath with gelatino-chloride, and, unless care is taken to thoroughly wash the alum away, trouble results. The less the hardening agents are used until the finish of the prints the better, as they tend to make the film impervious to the toning and fixing solutions.

Fixing should never be done with a freshly made solution of hypo. Firstly, because a newly made bath is very cold, therefore cannot act properly; secondly, hypo almost invariably contains some impurities, and always deposits sulphur if allowed to stand, and, should these instead be allowed to deposit upon the prints, they will tend to yellowness and fading. Unless the operator is in the habit of testing the hypo for acidity, it is advisable to add a small quantity of ammonia, as hypo is frequently acid, and many of the complaints of reduction to a large extent in fixing are generally traceable to acid hypo, besides which the acid helps the deposition of sulphur. The ammonia may be added in a similar way to that suggested for adding bicarbonate of soda to the toning bath. Always use at least one ounce of hypo to ten ounces of water, more rather than less, so as to form the soluble hyposulphite, or, more properly, thiosulphite of silver, which is easily dissolved away, instead of the insoluble one, which is obtained with very weak solutions of hypo, and do not fix too many prints with the same solution or fading is bound to ensue.

Toning and fixing proceed best when the solutions are at a temperature of about 65° Fahr. Where a little attention is paid to the above matters, I am sure that little or no trouble will be found with spoilt prints, loss of density, double toning, &c.

C. T. SUTTON.

#### WEISS'S SMOKE AND FUMES COLLECTOR FOR FLASHLIGHT PHOTOGRAPHY.

THE subject of this invention is an automatically working apparatus for collecting and enclosing the smoke and fumes generated through the igniting of the powder employed in the taking of instantaneous photographs. The essential feature of the invention is the arranging of a bag above the instantaneous light apparatus, this bag being in a collapsed state before the igniting of the flash powder, and leaving the lamp for the instantaneous lighting free, but after the ignition of the powder it unfolds automatically by means of the flame, and then encloses the instantaneous light apparatus, together with the smoke resulting from the ignition.

Figs. 1 and 2 show a form of the apparatus and its connexion with a lamp for instantaneous light, fig. 1 elevation illustrating the position of the apparatus before the igniting of the flash powder, and fig. 2 its position when actually effective, after the ignition, whilst fig. 3 is a plan view of a detail. Figs. 4 and 5 are sections of a slightly modified form of the apparatus.

The flash powder, 1, to be ignited lies on a table, 2, which is fixed on a stand, 3, 4. It is ignited, for example, by the forward motion of a carrier, 5, with a match, 6, the match being rubbed on a friction surface, which is not shown, and entering the body of the powder through an opening in the back, 7, of the table. The powder may, however, be ignited in any other manner.

To the rod, 3, of the stand, an arm, 8, is fixed. This arm carries the smoke bag, which is open below and closed above. The bag-like part, 9, is placed over a frame, 10 (plan view, fig. 3), and has sewn into it a ring, 11. To the arm, 8, levers, 12, 13, are pivoted; these levers, when in their horizontal position, support and bear the bag, 9, in the collapsed or folded state (fig. 1). To the shorter ends of the levers, cords, 14, 15, are fastened, which are kept stretched and carried through the flash powder, or, in other words, through the area of the flame. In fig. 1 the cords, 14, 15, are carried through an opening in the back, 7, of the table, then through the body of powder, 1, or, in other words, through the area of the flame, and are kept stretched in any suitable manner,

for example, by being wound around the guiding sleeve, 16, of the carrier, 5. In this condition the smoke collector apparatus is ready for use.

If the flash powder be now ignited, and at the same moment the photograph be taken, the flame produced burns through the cords, 14, 15, so that the levers, 12, 13, lose their hold, and the bag, which is loaded or charged with the ring, sliding down from the levers, unfolds. Thereby, the lamp for the instantaneous light, and the ascending smoke will be entirely surrounded, and the latter completely intercepted, this latter operation being further effected by pulling the cord, 17, which serves for contracting the bottom of the bag.

Fig. 2 shows the apparatus in this position, in which the levers, 12, 13, assume a vertical position by their own weight after the cords are burned through.

In order to make the apparatus again ready for use, the separated cords are united again, or new cords fastened to the levers, 12, 13; the arm,

8, is arranged suitably adjustable on the rod, 3, of the stand; the frame, 10, is arranged on a pin, 18, in the upper end of the arm, 8, by means of a central socket. Having regard to the fact that the table, 2, is of a suitable lengthy (or oblong) form, it is advisable to make the frame elliptical, and the bag of corresponding shape.

Figs. 4 and 5 illustrate, in section, a simplified form of the invention, from which the levers, 12, 13, are absent. The cords, 14, 15, are, in this case, fastened to hooks, 19, 20, rove through eyes or loops, 21, 22, 23, 28, 29, 30, in the bag, and eyes or loops, 24, 25, 26, 27, on the cross stay of the frame, and further on as arranged in fig. 1. Fig. 4 shows the bag, 9, in the folded state, the lower part, 9<sup>1</sup>, hanging down free. When the cords, 14, 15, are burned through, the bag unfolds through the dropping of the ring, 11 (fig. 5), whereupon the lower part, 9<sup>1</sup>, is closed by pulling the cord, 17.

#### NOTES FROM THE WEST OF SCOTLAND.

JUDGING from the experience of a few of the professional photographers in Glasgow, installations of electric lights in studios are not being attended with the happiest results. In one instance especially, where a firm of photographers have gone to a considerable outlay in fitting up an installation of arc lamps for portraiture in their studio, it has been found that the current supplied by the Glasgow Corporation was so unreliable as to quite interfere with the proper conduct of the business of the firm.

Then, again, it is no secret that on more than one important occasion the voltage that was supplied by the Glasgow Corporation was quite inadequate to feed the customary arc lamps employed in an ordinary cinematographic display in the Royal Art Institute, and in another important function held in Glasgow Chief Public Halls, where it was desired to photograph a celebrated concert party, the installation of electric arc lights could not be brought into requisition at all.

The outcome of all this is a distinct leaning on the part of a few of our leading photographers to turn their attention to a form of illumination that is more under their own personal control, such as a well-appointed installation of acetylene gas.

The introduction of acetylene gas into our studios so far has been slow, but it can be safely asserted that, in all cases where such has been introduced, the same has been attended with the most successful results, and at the present time there is a distinct inclination on the part of photographers to adopt such in preference to the uncertainty of the arc light.

Some time ago we drew our readers' attention to an important action that was likely to come before one of the law courts in Glasgow, in which a local camera club was being sued for the alleged offence of taking and exhibiting a snap-shot of a dealer. This cause has now been brought into Court, and of which the following is a condensed report of the grievance alleged:—

"ACTION AGAINST A CAMERA CLUB.—A rather curious action is pending against the Shettleston Camera Club. A case has been intimated by Mr. Charles McKerracher, dealer, Gray-street, Shettleston, against the Shettleston Camera Club (Robert Anderson, M.D., President; William Gordon, Vice-President; J. S. Wilson, Secretary; and H. Gray, Treasurer, of the said Club). Pursuer alleges that some of the members of the Club took three snap shots of him while in the pursuance of his calling in the Old Edinburgh-road, and that said photographs were exhibited at a lantern entertainment given recently by the Club. He further alleges that through this cause he has suffered much loss of business and personal inconvenience. The sum of 150*l.* as damages is claimed as compensation. The Club have had a meeting, and agreed to defend the action."

A very interesting series of photographic demonstrations was recently given before the Glasgow and West of Scotland Amateur Association, by Mr. T. N. Armstrong. These, among other minor items, included some valuable hints on the application of the flashlight to ordinary daylight exposure, as well as what must be termed an exceedingly simple method of making lantern slides from large-sized negatives by reduction through the camera with the aid of an ordinary paraffin lamp. In these demonstrations Mr. Armstrong used, in connexion with the turning of magnesium powder, a novel form of lamp for which he claimed an illumination of any extent up to ten thousand candle power, according to the quantity of powder used. It certainly was a surprise to the large audience that assembled on the occasion to witness the wonderful light that was produced.

The chief points of interest in connexion with the production of lantern slides by reduction through the camera, when merely an ordinary paraffin lamp was used, seemed to lay in the employment of a portrait combination of lenses, in conjunction with a more than rapid grade of lantern plate which enabled a very brief exposure to suffice. Mr. Armstrong explained that he was indebted to Messrs. Cadett & Neall for supplying him with these excellent plates. The results achieved before a crowded meeting were certainly strikingly successful, for, with an ordinary tissue paper, diffusing screen exposures of three minutes yielded most exquisite results.

The developer used was plain pyro and ammonia, which was mixed in the presence of the audience.

Mr. Willie Anderson of Partick also showed his method of making vignettied bromide prints, and in this he used his newly designed vignetter which is most portable and effectual. Mr. Anderson not only exposed a large number of prints, but developed the same in the presence of the meeting, and was most successful throughout the entire series of demonstrations.

#### YORKSHIRE PHOTOGRAPHIC SOCIETIES: PROPOSED UNION.

A SPECIAL Meeting, convened by circular issued at the instance of the Secretary of the Bradford Photographic Society, was held at the Grammar School, Bradford, on Friday evening last, at 7.30 p.m., to consider the desirability of establishing a Union of Yorkshire photographers and photographic societies.

The meeting was the outcome of the success which has been attained by the Bradford Exhibition and to the friction which has of late arisen between the Yorkshire societies and the affiliation with the Royal Photographic Society.

In response to the invitation the following gentlemen attended the meeting for the respective societies:—

Bradford Photographic Society, Messrs. B. J. Appleton, J. Akam, J. Woodall, W. A. Bell, P. Lund, F. Nicholson, H. G. Rogerson, G. Thistlethwaite, and E. Clough (Secretary *pro tem.*).

Halifax Camera Club, Messrs. J. W. Holland, C. Foster, G. Bower, and J. Abbey.

Leeds Photographic Society, Messrs. J. C. Coultas, T. Carter, A. W. Atkinson, H. B. Buckley, and John Woolf.

Yeadon and District Photographic Society, Mr. — Coupland.

Batley Photographic Club, Messrs. P. Sheard (President) and W. H. Atkinson (Secretary).

Heckmondwike Photographic Club, Messrs. A. Senior and T. W. Rhodes.

Keighley Photographic Club, Messrs. Thomas Heaps, J. W. Gill, and S. Bairstow.

Leeds Camera Club, Messrs. J. H. Gash (Secretary), W. J. Warren (President), R. Bourke (Vice-President), W. Rust (Vice-President), and J. Skilbeck (Committee).

Rodley Photographic Club, Mr. J. F. Ashley.

Huddersfield Photographic Society, Mr. W. A. Beevers.

Wakefield Photographic Society, Mr. W. Woodhead.

Hull Photographic Society, Messrs. J. Hollingworth and — Johnson.

Sheffield Photographic Society, Mr. George W. Blackwell.

Mr. Clough at the outset remarked that they must not consider that at all in the light of a formal meeting; it was practically in the nature of an experiment.

On the motion of Mr. Appleton, seconded by Mr. Frank Nicholson, Mr. Lund (Bradford) was voted to the chair.

Mr. Lund, on taking the chair, said it seemed to him that some sort of union amongst the various associations in Yorkshire was desirable, and was clearly indicated by the representative attendance that evening. Of course, there were adverse views on the subject, and he called upon

Mr. Clough, who read a letter from the Rotherham Photographic Society, which was to the effect that that organization considered that the advantages to be gained by such a movement as they had now under consideration were no greater than those already provided by the Royal Photographic Society, at the same time it was necessary. He should say he had received a large number of letters, in which approval was expressed of the scheme. Of course, those letters simply expressed the opinion of various hon. secretaries, and was not binding at all upon the various associations.

Mr. Warren insisted that it was of vital interest the meeting should know what associations expressed approval of the scheme.

Mr. Clough intimated that ten secretaries or officials had expressed approval of such a union as was contemplated by the circular.

On the suggestion of the Chairman, Mr. Clough undertook to explain the objects for which the meeting had been called. There had, he said, for some time past been a desire among various societies in Yorkshire to exchange opinions as to the desirability of a sort of federation amongst the various societies in Yorkshire; and, so far as he could see, the feeling was spreading every day. The Yorkshire district was so wide, that it was felt an impossibility to proceed until a small informal committee took the matter in hand, and, with this end in view, eight gentlemen had taken the matter in hand. The whole object of the Committee had been to bring, if possible, the matter to a head. They, of course, had drawn up a scheme, but it must not be taken that any preference should be given to that as compared with the suggestions of any individual. The desire had been to found a basis on which discussion might take place. The Committee that had been engaged on the preliminary work consisted of Messrs. Appleton, Thistlethwaite, Akam, F. Nicholson, H. G. Rogerson, P. Lund, and A. E. Clough.

Mr. Clough then submitted the following draft scheme, as recommended by the Committee:—

#### YORKSHIRE PHOTOGRAPHIC UNION.

##### PROBABLE FACILITIES GAINED BY UNION.

1. Intercourse and exchange of opinion between one society and another.
2. United action for the purpose of exhibitions or dealing with any question of importance to photographers in the county.
3. Interchange of prints and lantern slides.
4. Interchange of lecturers and lectures.
5. Annual excursion.
6. Annual meeting to be held at different centres.
7. Special railway fares.
8. Competitions in different branches of photography.

The interchange of prints could be achieved by means of a circulating portfolio under the control of a special committee. The interchange of slides might be effected conveniently in the following manner:—

Each society to send to headquarters no less than a given number of slides. These are submitted to a selection committee, who make up from them one or more sets for circulation in the usual manner.

These slides, when the circuit is completed, to be returned to their owners. All breakages are paid for by individual societies. The interchange of lecturers might advantageously be carried out on the following lines:—

By the establishment of, first, a voluntary lecturing and demonstrating staff composed of men who would come and give (a) three evenings each season; (b) six evenings each season; (c) nine evenings each season. To these voluntary lectures no charge shall be made for admission. The society engaging a lecturer shall pay his travelling expenses, and, if circumstances render it necessary, his hotel expenses also, provided hospitality is not offered. Some such arrangement as the following should be established in order to regulate the demand and supply of voluntary lectures: All societies in the Union to be allowed two voluntary lectures each season, and, in addition to that fixed number, one extra lecture for each approved lecture placed by that society at the disposal of the Union.

Secondly, a paid lecturing staff, comprising duly approved and selected lecturers, residing either in Yorkshire or elsewhere, whom the Union consider desirable to have on their books, and who allow a special commission to the Union on all engagements.

As to the interchange of lectures, the Union might purchase each season one or more written lectures from qualified writers, which would be circulated among the societies in the Union in the usual manner.

9. Juries of selection.

10. A meeting of officials for exchange of lectures.

That questions of principle be taken up by the Union with railway companies.

That the Union arrange, if desired, and when possible, for privileges for working in private places of interest, i.e., places not open to the general public.

#### CONSTITUTION.

A President, six Vice-Presidents, Recording Secretary, Business Secretary, Committee, Treasurer, members, and associates.

Members may be either individuals who have joined the Union by paying a subscription of 5s. per annum, or delegate members elected by societies as their representatives.

All members of the Society who have joined the Union become associates, and are entitled to attend the annual excursion and the General Meeting. Photographers not members of any club may become associates on payment of 1s. per annum, or members on payment of 10s. 6d. per annum. Societies can enjoy the privileges of the Union on the following terms: Those having a membership roll of fifty or less, 10s. per annum; 15s. for those having 100 or less; and 20s. for all above that number.

These societies shall be allowed to send to the General Committee one, two, or three member delegates.

**General Committee.**—The individual or unattached members and the delegates members shall form the General Committee of the Union. The General Committee shall elect twenty-five of its number to form a Managing Committee. The Managing Committee shall be nominated a month prior to the General Meeting, and elected by voting papers sent to every member by post, to be returned five clear days prior to the annual meeting. The whole of the officers and Managing Committee shall retire annually, but be eligible for re-election. Associates have no vote. The Managing Committee shall elect the officers.

The Chairman pointed out that it was at the option of the members to revise the suggested scheme in every respect. Of course, if they decided on any scheme, a meeting would have to follow for the election of officers, &c.

Mr. W. Rust (Leeds) thought some reason should be given for the formation of the proposed combination.

Mr. Bourke (Leeds) was under the impression that there was already in Yorkshire a sort of society carrying out similar objects to those it was proposed the new organization should devote itself.

Mr. Hollingsworth (Hull) thought that their best plan would be to accept the draft scheme, and each delegate submit it to his Association for consideration. At a subsequent meeting they would have something definite to go upon.

The Chairman asked that some one should suggest that some such a Union as had been suggested was desirable; of course, if the meeting was against the proposal altogether, the whole thing fell to the ground.

Mr. Hollingsworth moved—"That the formation of a Union of Yorkshire Photographic Societies is desirable."

This was seconded by Mr. Carter (Leeds), and carried without opposition.

The Chairman thought it would be advisable to take the various items in the scheme *seriatim*.

Mr. Sheard (Batley) thought they had gone as far as they could that night, and suggested that the scheme as propounded by the Committee should be put in the possession of all the societies in Yorkshire, so that it might be duly considered. Of course, the expense of the circulation could be arranged amongst themselves. He moved a resolution to the effect.

Mr. T. Heaps (Keighley) seconded this.

It was agreed to defer the motion.

Mr. Rust again expressed his inability to discover any reasons which had been put forward for bringing the Union into existence.

The Chairman pointed out that the reasons were embodied in the draft scheme, and it seemed to him there was a general feeling in favour of it.

Mr. Bourke (Leeds) maintained that there was a body already existing in Yorkshire devoted to similar objects as suggested that night. In connexion with the affair a meeting was duly held in Leeds last year.

Mr. Appleton thought that the matter referred to by Mr. Bourke did not interfere with the present scheme at all.

Mr. Warren agreed with this view, maintaining there was a need for the proposed Union.

After further discussion, clauses 1, 2, 3, 4, 5, of the draft scheme were agreed to.

As to the Annual Meetings it was agreed to add to No. 6, "To be held in April at different centres."

Clause No. 7, as to special railway fares, brought about some discussion, the idea being that the resolution carried should allow members of the proposed Union, on production of cards of membership, to travel at reduced fares, such as maintained with regard to the Yorkshire Naturalists' Union and other similar societies.

As to No. 8, "Competitions with different branches of photography."

The Chairman remarked that it was impossible to foresee how far this

would go. Special awards might be given in connexion with important exhibitions.

Mr. Warren thought, in connexion with No. 9, the scheme might include an arrangement for registering Judges, so that in club competitions they would know where to apply.

The meeting considered Mr. Warren's idea a valuable one, the existence of something after the nature of a "judicial bench" being desirable, and it was decided to add to the item, "Election of a Judicial Bench."

No. 10 gave rise to considerable debate, and it was resolved to add to that item, "That questions of principle be taken up by the Union with railway companies."

As to the exchange of lectures, the Chairman said the idea was that the Union would have under its control all grades of lecturers, many of whom might be acceptable in small societies, but at the same time not able to take up a position at societies such as Leeds and Bradford. The best plan would be for each society to place its programme before the Central Committee.

Mr. Warren asked if it was seriously intended that no society, however influential, should have more than three representatives present at any committee meeting?

The Chairman said that was certainly the idea. It was not intended that the larger societies should dominate over the smaller ones.

It was ultimately decided to add the following items to the draft scheme:—

"Juries of Selection."

"A meeting of officials for exchange of lectures."

"That questions of principle be taken up by the Union with railway companies."

"That the Union arrange, if desired, and when possible, for privileges for working in private places of interest, i.e., places not open to the general public."

It was proposed by Mr. Sheard, and carried *nem. con.*—That an association with the title of the Yorkshire Photographic Union be formed, and that the provisional scheme as revised and approved be printed, and forwarded to the secretaries of every society in Yorkshire.

Mr. Warren was appointed Hon. Treasurer *pro tem.*, and the meeting adjourned to February 9.

#### PERTSHIRE SOCIETY OF NATURAL SCIENCE (PHOTOGRAPHIC SECTION) EXHIBITION.

For a first Exhibition by a young Society, or rather by a newly re-suscitated branch of an old Society, this Exhibition, opened on Wednesday, January 25, is a very creditable one. The manner in which the members have contributed to the confined classes shows an unusual amount of enthusiasm; to be critical, we might in some cases say their zeal had over-run their discretion, but it is so comforting to find so much whole-hearted enthusiasm that criticism on this point is stilled. In five members' classes we have 176 entries, the most popular naturally being the landscape, which totals sixty-nine entries, including many good things. The best work in the various members' classes is submitted by Messrs. W. Ellison and A. S. Nicol, the latter taking the silver medal for the best print exhibited in the members' classes with a photographic joke, entitled *A Study for a Saint*; the "saint," it may be stated, stripped of his surroundings, is simply a bare-footed youngster, staring benignly at the spectator. A few members have yet to learn that a white, blank sky is not true to nature, but the Exhibition should teach this. As might be expected from a sub section of a Society with the above title, scientific work is more *en evidence* than is usual at photographic exhibitions. Mr. R. Kidstone shows a number of micro photographs, clear in detail and of perfect technique; Mr. Charles Kirk has a series of views of birds' nests, some of which might well compare with those of Mr. Kearton; and Mr. A. S. Reid, M.A., exhibits some very good photographs of geological formation that will form a valuable help to geological students. *A Stencil Pattern by Photography*, by Mr. A. S. Nicol, is at once, suggestive and useful.

In the Open Classes the local men exhibit largely, but there are also entries from a wider area. Mr. W. Louis Primrose, Glasgow, in the Landscape and Seascape Class wins the silver medal with *The Brook*, a photograph which, while obeying the canons of composition, is wanting in some point of interest. Second place is taken by Mr. E. S. Lyttel, Glenalmond, with *Evening*, a rather indifferent interpretation of a hackneyed subject, a photograph with a similar title by Mr. W. F. Slater, Camberwell, being thought by many superior to the bronze medal print, but we understand the Judges were unanimous in their verdict.

In the Portraits, Figure, and Animal Studies, pride of place is taken by a local professional, Mr. John Spark, Perth, with *Faith*. The photograph may not, perhaps, quite carry out the title—the subject is an ambitious and difficult one—but it shows that even in the provinces there are professionals with a real love for their profession and a desire for some better than "the usual thing." A sunning down of the light on the drapery and the removal of an obtrusive arm would improve this photograph, while a quieter frame would considerably aid in securing the harmony of the whole. The bronze medal is awarded to *Pointers at Work*, by Mr. W. J. Croall, Edinburgh, a picture that secured much attention at the Glasgow International Exhibition of 1897 under the title of

*Sporting Dogs at Work.* In this class Dr. Fergusson, Cheltenham, shows a beautiful series of *Kitten Studies*, some of which figure in the catalogue as *Kitty Study*. Mr. W. F. Slater, Camberwell, shows his well-known *Pelican*, Mr. Alex. Geekie, Coupar Angus, has a really good thing in *Study of a Head* and *A Little Girl's Head*—a camera sketch is sufficiently away from "the usual thing" to be noticeable. Messrs. W. M. Warneuke and J. Craig Annan show a selection of their well-known works, and exhibits are forwarded from Messrs. G. H. J. Burrows and John Spark, Perth; Mr. A. F. Mackenzie; and the Art Photographic Company, Perth. The work of Mr. Mackenzie contains portraits of prominent men like Sir John Millais, Mr. W. E. Gladstone, &c., and should be seen by all who value first-class technique with a pleasing and artistic arrangement of the subject.

We ought to mention that admission to the Exhibition, which is held in one of Perth's best modern buildings, the Sandeman Free Library, is free, and the Exhibition should be a valuable education to the citizens of "the fair city," who are taking full advantage of the privilege offered.

Appended is the prize list. Judges: Messrs. W. M. Warneuke, Glasgow; J. Cox Cox, Loches; and William Fraser, Perth.

#### MEMBERS' COMPETITIONS.

*Landscapes and Seascapes, with or without Figures.*—Bronze medal, Mr. Henry Shields, *Evening, Loch Fyne*; certificate, Mr. William Ellison, *Autumn Scene*.

*Portrait, Figure, and Animal Studies.*—Bronze medal, Mr. William Ellison, *The Stocking-knitter*; certificate, Mr. Henry Shields, *Tommy*.

*Instantaneous Work.*—Bronze medal, Mr. A. S. Read, M.A., *Hurdle Race*.

*Architecture, interior or exterior.*—Bronze medal, *Interior of St. Paul's, Antwerp*; certificate, Miss M. Thomas, *Balmerino Abbey*.

*Flower Studies, Statuary, &c.*—Bronze medal, Mr. Charles Kirk, *Nest of Willow Wren*; certificate, Mr. A. W. Brown, *Grapes*.

*Lantern Slides.*—Bronze medal, Mr. Henry Shields; certificate, Mr. Harry Coates.

Silver medal for best in above classes.—Mr. A. S. Nicol, *A Design for a Saint*.

#### OPEN CLASSES.

*Landscape and Seascape.*—Silver medal, W. Louis Primrose, Glasgow, *The Brook*. Bronze medal, G. S. Lyttel, Glenalmond, *Evening*.

*Portrait, Figure, and Animal Studies.*—Silver medal, John Spark, Perth, *Faith*; bronze medal, W. J. Croall, Edinburgh, *Pointers at Work*.

*Lantern Slides.*—Silver medal, E. R. Bull, London; bronze medal, Graystone Bird, Bath.

*Apparatus.*—Silver medal, J. Lizars, Glasgow; bronze medal, C. F. S. Burrows, Perth.

At the opening *Conversations* Mr. Henry Coates (President) presided, and Mr. Charles Reid, Wishaw, delivered a lecture illustrated with his famous lantern slides. The Secretaries (Colonel Campbell and Mr. C. F. S. Burrows), with their Committee, deserve all credit for the successful outcome of their labours.

#### THE INTERNATIONAL PHOTOGRAPHIC EXHIBITION AT BIRMINGHAM.

We have received a proof prospectus from Mr. Welford of this Exhibition, which is to form part of the National Trades and Industrial Exhibition at Bingley Hall, Birmingham, from March 20 to May 13. Amongst the various classes we note one for beginners, and another for amateurs who have not previously gained awards. Ladies too are catered for, there being one class reserved to them, and, in addition, a special silver medal for the best work by a lady in any class. Although previously medalled work is not debarred, there is a Champion Class, but it is on new lines. The three best pictures in the whole Exhibition receive the champion medals first, then they are debarred from medals in the classes for which they may be entered. Mr. Welford believes this to be the first time that this has been done. All pictures, however, remain eligible for the special prizes, which are numerous, and consist of medals, hand cameras, and five cash prizes ranging from 5l. 5s. to 1l. 1s. The rules and regulations are very complete, and things are defined that are often left open to question. All the competitions except two are open to amateurs and professionals alike. The Judges are Messrs. Harold Baker, B. Child Bayley, and A. Horsley Hinton. In order to assist exhibitors as much as possible, Mr. Welford will arrange for the transfer of frames from the Birmingham Society's Exhibition, which closes on March 4, to Bingley Hall. He will also receive exhibits from the South London Exhibition, which closes on March 11, up to Tuesday night, March 14, provided their exhibitors can arrange for their being dispatched on the Monday from London. All other exhibits must reach him on the 11th. For the benefit of London exhibitors, he will accept frames unpacked at his offices in Chancery-lane up to Wednesday night, March 8; these will be taken to Birmingham, and returned to his offices at the close of the Exhibition at a charge of 6d. per frame. They must not, however, be packed in cases or boxes. As these conveniences must entail considerable extra work for Mr. Welford, we trust they will be

appreciated. In view of recent complaints as to receiving notice of awards, he also guarantees that a printed list of awards shall be posted to every exhibitor at the earliest possible moment. Full particulars are now ready, and may be obtained from Mr. Walter D. Welford, 19, Southampton-buildings, Chancery-lane, London, W.C.

#### KODAK, LIMITED.

THE First Ordinary Meeting of the shareholders of the above-named Company was held at Winchester House, Old Broad-street, E.C., on January 26, under the presidency of Sir James Pender, Bart., M.P., Chairman of Directors.

After the Secretary had read out the notice convening the meeting, the Chairman said that this was only the formal meeting required by the statute, and, as the Company had been so recently formed, they had no definite business to put before the meeting. The Company was registered on November 14, and, although they had until March 13 to hold the statutory meeting, the Directors thought it advisable to meet the shareholders as soon as they were in a position to report the completion of the purchase, and to give some information of the progress and prospects of the business. The purchase was completed on January 20, and, in anticipation of the completion, notices of the meeting were sent out. The Company was now in entire possession of the undertaking of the English Company, and the businesses in France and Germany, as well as of ninety-eight per cent. of the shares in the American Company. With regard to the issue of shares in November last, it was probably a matter of common knowledge that, although no part of the capital was underwritten or guaranteed, the shares issued to the public, when the Company was brought out, were largely over-subscribed. Shareholders would naturally desire to know how the combined businesses have prospered, and those who were also shareholders in the Eastman's Photographic Materials Company, Limited, have already been notified of the progress of the Company to the end of last September. He was now glad to state that the rate of increase in the sales for the first nine months of 1898 have been maintained throughout, and, further, that the profits for the whole year have been of an eminently satisfactory nature. Although the audit for 1898 was not yet completed, the accounts have been made up by the Company's accountants on the principle laid down by Messrs. Price, Waterhouse, & Company, and showed a profit of over 230,000l. For purposes of comparison, it might be stated that the profits for the year 1897 were 185,232l. That showed a very marked increase, and they would observe that it was a continuation of the steady increase that has been shown for several years. The sales and the profits have been annually increasing, and, with regard to the current year (1899) it would be seen, on the basis of those figures, that there would remain, after payment of the preference dividend, sufficient to pay a handsome dividend on the ordinary shares, and still leave a large sum for the reserve fund. With regard to last year's profits, they took the profits of the whole year in respect of the businesses in England, France, and Germany, subject to payment of twenty per cent. per annum to the shareholders in the English Company. The margin on that was greatly in favour of their Company. They were also entitled to ninety-eight per cent. of the profits of the American Company from October 1 last. With regard to 1899, he might inform them that it has been arranged that the dividends on Kodak, Limited, should accrue from January 1, 1899. Assuming that the profits for the present year were as good as those of 1897 and 1898, they proposed, as has been the custom in America, to pay dividends quarterly, so that they might expect the first interim dividend in April next. It was an engagement in the prospectus that was issued that the cash in hand and at the banks of the combined businesses on January 1, 1899, should not be less than 150,000l. As a matter of fact, the cash balances at the date mentioned exceeded 165,000l. An application has been made to the London Stock Exchange for a settlement and a quotation of the ordinary and the preference shares. Their business in every country where organized was doing well and increasing, and they still have enormous territory and fields to exploit. They have excellent new goods for 1899, to meet a keep ahead of every demand, and they were also opening new depôts, in fact one has been opened at Brussels. He could not conclude his statement without referring to the death of his colleague, Mr. George Dickman. Many of them would have been acquainted with him, and would know of his fine qualities without any word from the chair. As the most prominent officer of the old Company on this side, and one who did much to establish the business on a firm and sound basis, they must all pay Mr. Dickman's memory the tribute of their sincere esteem and admiration.

#### Our Editorial Table.

MESSRS. MORLEY & COOPER, of 70, Upper-street, Islington, N., are issuing a special list devoted to hand cameras, of which there are several illustrated and described. The three latest Kodaks are also mentioned in the list.

## THE BARNET EXTRA RAPID PLATES.

Manufactured by Elliott &amp; Son, Barnet, N.

Messrs. ELLIOTT have recently increased the rapidity of their favourite brand of Extra-Rapid dry plates, and, taking advantage of the dull weather experienced at the commencement of the present week, we sought the opportunity to subject the plates to practical trial in circumstances analogous to those prevailing in studio work. In other words we tried the plates on home portrait subjects and interiors, giving what we should regard as very short exposures. We were convinced from our experiments that the Barnet Extra-rapid plates possess a very high degree of rapidity indeed, and we have no hesitation in endorsing Messrs. Elliott's recommendation of them for photographing interiors and badly illuminated subjects. In the studio, too, they should prove invaluable. Under stress of purposely forced development the plates resisted any tendency to fog, and a careful examination of the deposit showed it to be singularly fine in the grain. Thus the Barnet Extra-rapid plates have a combination of good qualities which should ensure them a good run amongst all classes of photographers.

## DEUTSCHER PHOTOGRAPHEN-KALENDER, 1899.

Verlag der Deutschen Photographen Zeitung, Weimar.

This excellent publication will soon attain its majority, being now in its eighteenth year, and its usefulness has been considerably increased by dividing the present issue into two volumes. The first, in the form of a pocket-book, contains a diary, a collection of formulæ, tables, and other statistical information, selected with care to meet the wants of the professional photographer. The second volume is a directory, comprising lists of the German photographic societies, officers of foreign photographic societies, and a list of photographic dealers throughout Germany. The book should be on the shelves of every German photographer.

## CATALOGUES RECEIVED.

G. W. Wilson &amp; Co., Limited, 2, St. Swithin-street, Aberdeen.

From the renowned house of G. W. Wilson, of Aberdeen, we have received their latest issued descriptive list of sets of lantern slides. The number extends to several hundred, and for subjects there are cathedral, historical, castles, picturesque old towns, both at home and abroad, scenery, Bible history, science themes, and others too numerous for mention. The list should be in the possession of all those who appreciate a beautiful lantern slide. For providing such, Messrs. Wilson's name has long been a household word wherever the optical lantern is used. In a prefatory note Messrs. Wilson & Co. say they supply good slides and expect a fair price. They do not supply job lots; they do not make their slides from cheap magazine or newspaper woodcuts; and they do not pirate other makers' slides. Such a business policy deserves the utmost encouragement.

In view of stocktaking, Messrs. George Houghton & Son, of 89, High Holborn, are issuing a list of a few new and second-hand lenses, which are to be cleared at greatly reduced prices. This list will be forwarded to any of our readers on application.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, February 8, at eight o'clock. Members' Open Night.

LEEDS CAMERA CLUB CONVERSATION.—The Leeds Camera Club had their Annual Conversations, on Wednesday evening, January 25, at the Alexandra Hall, about 250 of the members and their friends being present. A reception was held by the President (Mr. W. J. Warren) and Mrs. Warren, and Mrs. Warren afterwards distributed the prize medals to the various winners. The winning prints were on view during the evening. Among the numerous attractions provided by the Committee was the Kromskop, exhibited by Mr. Fox; a series of microscopical exhibits by Messrs. Gash, Birch and Fox; a demonstration of flashlight photography by Mr. Homburg and Mr. Morfitt; a Röntgen demonstration by Mr. J. H. Gash, lantern and cinematograph by Mr. R. Burke, interspersed with songs and music, under the arrangement of Mr. Palliser. Mr. Eastman gave a display of telephonic apparatus, a very enjoyable evening concluding with a Christmas tree distribution to every child present, under the arrangement of Mr. and Mrs. J. H. Gash.

THE NORTHAMPTON PHOTOGRAPHIC EXHIBITION.—This Exhibition will be held in the Assembly Rooms, Town Hall, Northampton, from Thursday, February 16, to Thursday, February 23, 1899. The Open classes are: (a) Open to professional and amateur photographers residing in the town and county of Northampton only:—Not previously medalled: 1. Portraiture and Figure Studies, including Animals; 2. Landscape, Seascape, and River Scenery; 3. Architecture, interior and exterior; 4. Hand-camera Work (direct pictures only); 5. Lantern Slides (sets of four). (b) Open Classes:—6. Champion Class, Pictures which have previously received an award at any exhibition. Not previously medalled: 7. Portraiture and Genre Studies and Animals; 8. Architecture, interior and exterior; 9. Hand-camera Work (direct pictures only); 10. Landscape, Seascape, and River Scenery; 11. Lantern slides (sets of four). Entry forms and further information can be obtained from the Hon. Secretaries, Messrs. E. J. Felce, 53 Adams' Avenue, Northampton, and E. G. Holt, 35, Ivy-road, Northampton. The date for receiving entry forms has been extended to February 6.

RÖNTGEN SOCIETY.—The next General Meeting will take place on Tuesday, February 7, at eight p.m., at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Mr. C. W. Mansell-Moullin, M.D., Oxon, F.R.C.S. Mr. Wilson Noble will read a paper on a modified form of Toepler mercury pump. There will be a discussion on the Röntgen-ray photography of soft tissues, introduced by the President.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION ANNUAL EXHIBITION.—At the Grand Assembly Rooms, Barras Bridge, Newcastle, an Exhibition of photographic work, was held on Monday week, the exhibits comprising the work of members sent in for the competitions of the Newcastle and Northern Counties Photographic Association, and a loan collection by the principal workers of the day. The standard of work shown was high, pictorial merit and technical skill being very conspicuously combined in most cases. The list of awards for the members' competitions is as follows:—Set of three landscapes, bronze medal, Mr. W. S. Corder, North Shields. Set of three architectural subjects, bronze medal, Mr. A. Cowling, South Shields. Set of hand-camera pictures, bronze medal, Mr. J. Rhagg, Newcastle. Set of lantern slides, bronze medal, Mr. G. B. Bainbridge, Newcastle. Enlargements, silver medal, Mr. A. B. Gardner, Newcastle; bronze medal, Mr. Burton Graham, Whiteby. Portraiture, silver medal, Mr. Andrew Peddie, Durham. Stereoscopic pictures, silver medal, Mr. H. G. Ridgway, Sunderland; bronze medal, Mr. W. H. Nixon, Newcastle. Messrs. P. M. Law, Newcastle, and R. Hauxwell, Durham, were the Judges. At the opening ceremony Mr. J. P. Gibson presided, and amongst those present were the Rev. Principal Gurney, Mr. Edgar Lee (President of the Association), Mr. Fred. Park, Mr. Cowan, Mr. J. S. B. Bell, Mr. John Watson, and the Hon. Secretaries, Mr. W. Thompson and Mr. Parker Brewis.

## Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

February.	Name of Society.	Subject.
6.....	Barnet and District .....	Demonstration: Development, &c. T. McWalter.
6.....	Kingston-on-Thames .....	Lecture. Rev. F. C. Lambert, M.A.
6.....	Putney .....	Development and Toning Solis Paper. The Eastman Company.

10.....	Leeds Photo. Society .....	Annual Dinner.
10.....	Plymouth .....	Members' Lantern Night.

## LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 26.—Mr. J. S. Teape in the chair.

Mr. T. E. H. BULLEN, referring to his paper on development of printing-out paper, delivered last week, said the question had been raised as to the possibility of getting uniformity of tone by development. He now showed several cards bearing, some of them, six prints of the same negative, and others three prints, made by the development process, all of which were particularly uniform in tone and depth of printing, indeed superior in these respects to much of the ordinary professional work. While these prints showed the possibility of securing them a uniform batch, an important factor in the attempt was the use of one brand of paper and one developer for the different prints which it was desired should resemble one another. Any toning formula, Mr. Bullen had reason to believe, would answer with prints developed by the method described, provided that a thorough washing in water followed the salt bath to which the prints were subjected after development.

Mr. LEWIS MEDLAND brought up a number of slides, taken in the pre-kina-matographic days, to show the many diverse phases of movement in horse racing, leaping, sports, the flight of birds, &c. The exposures in many instances were so short as one five-hundredth of a second, effected with Newman & Guardia's Celeritas shutter, and the several pictures brought before the members evoked a large share of appreciative remarks.

Mr. T. E. FRESHWATER exhibited a series of slides from photographs of the stuffed birds and animals in the collection at the Natural History Museum at South Kensington. All the specimens had to be photographed through the glass sides of the cases, and the success of Mr. Freshwater's efforts to avoid reflections in so doing was the subject of some comment. He said that the

photographer attempting this class of work was confronted with difficulties which exercised all the skill of the operator. There were many bright points to be avoided, reflections from the lens mount, bright screws on the camera, &c., and surrounding objects. He made use of a large black cloth (with an aperture for the lens to poke through), which he carried right up on some support to keep off these reflections. The background was a plain tinted grey brown material, with a white back, giving one the option of two surfaces. There was plenty of light, which sometimes had to be moderated by drawing the blinds. The exposures, with a lens stopped down somewhat, ran very often into minutes. A few of the slides were tinted, and all of them very interesting.

Mr. and Mrs. Welford and Mr. Bullen also contributed a selection of work—Convention pictures, landscapes and flowers.

#### PHOTOGRAPHIC CLUB.

JANUARY 25.—Mr. Lewis Medland in the chair.

Mr. R. CHILD BAYLEY gave a lantern lecture, entitled

#### THE HAND CAMERA AT HOME AND ABROAD,

in his usual bright and humorous way. Particularly interesting, on account of their present rarity, were the pictures of Spitzbergen, visited the year before last, which gave a very good idea of the features of this island, although to be able to appreciate the degree of colouring in the icebergs and glaciers nothing short of a visit would suffice. The remaining pictures covered the Norwegian coast between Bergen and Hammerfest as seen on a trip amongst the fjords, and included the results of a trip up the Rhine and Moselle, whilst the home subjects centered in the shipping at Ramsgate and the neighbouring district. The lecture was fully appreciated.

**Croydon Microscopical and Natural History Club, and Photographic Section.**—At the Twenty-ninth Annual General Meeting of this Club, held on January 17 last, William Whitaker, Esq., F.R.S., P.G.S., was elected President, and the following gentlemen form the general Committee, i.e., Messrs. J. H. Baldock, F.C.S.; J. Epps, jun., F.Z.S.; H. D. Gower; A. J. Hogg; G. E. Newby; E. J. Platts; E. Pierce, and N. F. Roberts, F.G.S. *Hon. Secretary:* R. F. Grundy. *Librarian:* A. Roods, F.S.I. The Photographic Committee comprise the following members: Messrs. J. H. Baldock (Lanternist and Recorder), H. D. Gower, E. Pierce (Hon. Secretary), E. J. Platts, A. Roods, C. J. L. Russell, and A. Weightman. The outgoing President, Dr. Hobson, then read the annual address, reviewing the work done by the Club, and its various sections during the past year, and which will be published in the *Transactions of the Club*.

**Birmingham Photographic Society.**—January 24.—Mr. HAROLD BAKER gave a demonstration of

#### BROMIDE PRINTING.

In his opening remarks Mr. Baker expressed surprise that bromide paper was not used more, as the variety of papers now upon the market made it possible to produce good prints from almost any kind of negative, and a variety of tones could be produced by soaking in a hot solution of alum and hypo, and other methods. The great cause of failure, he considered, was due to using a deep ruby light to develop by instead of a plentiful supply of yellow or orange. In some cases it was advantageous to judge of the necessary amount of development required by looking through the print in the same way as in development of negatives. It was advisable to cover the front of the printing frame with tissue paper in order to diffuse the light, and so prevent any small scratches or bits of dust that may be on the back of the negative showing as white marks upon the resulting print. With small prints it was advisable not to soak the paper in water before developing, but to put straight into the developer. If prints are previously soaked in water it very often leads to uneven development. Referring to warm tones, Mr. Baker preferred to dry his prints before putting them into the hot alum and hypo toning bath, as the risk of frilling was much reduced by so doing.

## Patent News.

THE following applications for Patents were made between January 16 and January 21, 1899:—

**PHOTOGRAPHY IN NATURAL COLOURS.**—No. 944. "An Improved and Simplified Method of taking Photographs in Natural Colours." A. LANDER. **PRINT AND PLATE-WASHER.**—No. 959. "Photographic Print and Plate-washer." G. A. CARRUTHERS.

**OPTICAL PROJECTION.**—No. 993. "Improvements in or relating to Optical Projection Apparatus for Advertising and Other Purposes." W. L. CAMPBELL.

**DEVELOPING AND FIXING APPARATUS.**—No. 1015. "Apparatus for Developing and Fixing Photographic Films and Plates." Communicated by R. Fleischer. A. M. CLARK.

**PRINTING.**—No. 1129. "Improvements in Printing by Photography." A. M. BARNES and E. COWPER.

**CAMERAS AND ENLARGING LANTERNS.**—No. 1130. "Improvements in Cameras and Enlarging Lanterns." A. M. BARNES and E. COWPER.

**PROJECTION APPARATUS.**—No. 1132. "Improvements in connection with Photographic Enlarging or Projection Apparatus." A. M. BARNES and E. COWPER.

**FINDERS.**—No. 1162. "Improvements in Photographic Finders or View-meters." J. E. THORNTON and C. F. S. ROTHWELL.

**FLASHLIGHT.**—No. 1388. "Producing Flashlight for Photographic Purposes." F. W. EMUSS and M. P. PROUT.

**CAMERAS.**—No. 1471. "Improvements in or relating to Photographic Cameras." G. W. BASE.

#### FORTHCOMING EXHIBITIONS.

1899.

- February 4-25 ..... Edinburgh Photographic Society. Hon. Secretary, J. S. McCulloch, 2, George-street, Edinburgh.  
 ,, 13-18 ..... Photographic Society of Ireland. Hon. Secretary, 35, Dawson-street, Dublin.  
 ,, 16-23 ..... Northampton. E. J. Felse, 53, Adams-avenue, Northampton.  
 ,, 21-24 ..... Hastings and St. Leonards. Exhibition Secretary, A. Brooker, 21a, Wellington-place, Hastings.  
 ,, 23-25 ..... Woolwich Photographic Society. Hon. Secretary, F. W. Machen, 161, Griffin-road, Plumstead, S.E.  
 ,, 27-March 4. Birmingham. C. J. Fowler, Court Mount, Erdington, near Birmingham.  
 March 4-11 ..... South London. Hon. Secretary, A. E. Allen, 27, Princes-square, Kennington Cross, S.E.  
 ,, 20-May 13 ... National Trades and Industrial Exhibition, Bingley Hall, Birmingham. George Stanley, Manager.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### PLATINOTYPE PRINTING.

To the EDITORS.

GENTLEMEN,—In reply to Tom Reveley and others, re platinotype printing, having had many years' experience, I am of opinion that all difficulties with respect to mealiness, lines, &c., will be surmounted by using distilled, not merely boiled, water. This is only necessary for making developer, and can be procured at any decent chemist's establishment.—I am, yours, &c.,

W. COLES.

Grasmere, Acock's-green, Birmingham, January 24, 1899.

To the EDITORS.

GENTLEMEN,—I have noticed correspondents' complaints in the last two issues of the JOURNAL re the platinotype paper. Having had many years' experience with the platinotype process, I think that I shall not be out of place in giving my opinion. At different times I have had much trouble with the different papers supplied by the Platinotype Company, but, by thorough investigation, have found the cause of the trouble, and almost invariably have found it faulty manipulation on my part. Printers are, as a rule, only too ready to blame the Company for supplying bad paper when they are really themselves at fault. Employers are also often just as ready to blame the printer; but there are, undoubtedly, occasions when paper is to blame for the faulty result, and in such case it is hard that the printer should suffer.

My belief is that the mischief may occur either in the sensitiser, or, most probably, in the dressing of the paper before sensitising. Several printers, to my knowledge, are having the same trouble with the paper that your correspondents complain of; in fact, only a few days ago I had a print given me with exactly the same marks and lines, &c., as described by correspondents.

I enclose a piece of platinotype paper, that you may see for yourself the result.—I am, yours, &c.,

H. ANDREW.

166-8, Strand, London, January 24, 1899.

[At page 68 of the present number of the JOURNAL there is a short article by Mr. H. W. Bennett, one of our leading photographers, who has had a long experience in platinotype printing, which draws attention to the most probable causes of the failures with that process of which our correspondents have been complaining during the last few weeks.—EDS.]

#### ABOLISHING THE DARK ROOM.

To the EDITORS.

GENTLEMEN,—I among many others, doubtless, was much interested in Mr. Howard Farmer's account, published in your issue of January 20, of his method of illuminating a dark room.

He has, however, left out the cream of the whole matter, namely, the composition of the liquid light filter, and the illustration is not as clear as it might be.

Is the lamp, A, shaded on three sides, and only throwing light down through the light filter?

If so, why not put a gas flame immediately over the light filter, C, with a ventilated cover over it?

If you could give more information on these points in an early issue, you would much oblige.—I am, yours, &c.,  
January 26, 1899. A GROPER IN DARK-ROOM DARKNESS.

In the discussion that followed the reading of his paper Mr. Farmer stated that at present he could not divulge the nature of the colour-filter solution. The construction of the lamp is as our correspondent describes it. As to his suggestion to place the flame over the light filter, possibly he had better address Mr. Farmer, at 209, Regent-street, on the subject. He may have some reason not given in his paper for the particular form of construction adopted.—[Eds.]

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

E. F. Field, 5, Albion-place, Maid's-tone.—Photograph of Eleanor Marx Ave'ing.

W. H. Dodgson, 16, Henry-street, Blackburn.—Photograph of "Big Sea Breaking on Poard."

Lovell, 27, Wellington-row, Whitehaven.—Two Photographs of J. Blinkin'op, Postman, Whitehaven.

F. Coghlan, 31, Carlisle-road, Londonderry.—Three Photographs of Count Arthur Moore, Unionist Candidate for Derry City.

RECEIVED.—X. Y. Z.; C. B.; F. J. WRIGHT. These and others in our next. STUART.—The first-named.

PYRO.—We are sorry to say we have not retained the address.

C. H. CHASE.—We believe so; but you had better make further inquiries through a commercial channel.

WEST RIDING PHOTO-ENGRAVING COMPANY.—Messrs. Morgan & Kidd, of Richmond, S.W., undertake such work.

PLATINO.—Thanks for your letter. What has been published in this and our previous issue sufficiently meets the case, we think.

A. E. S.—We should be inclined to think that the water you use is slightly contaminated with iron. That would produce the markings.

UNO.—We do not think the firm named would be likely to receive a pupil. Possibly the London Stereoscopic Company, 54, Cheapside, E.C., would.

R. RICHMOND.—The Science and Practice of Photography, by Mr. Chapman Jones, published by Messrs. Hiffe, St. Bride-street, E.C., would meet your case. It could be carried in the coat pocket.

W. S. WALTERS.—1. Dissolve one ounce of potassium bromide in nine ounces one drachm of water, and you have it. Messrs. Percy Lund & Co., Bradford, publish a little book on the subject by Mr. Bool.

GAS BAGS.—B. EVAN. If the gas bags have been lying by for many years and become so very hard, and, when softened before the fire, show many leakages, we should say they are perished and cannot be effectually repaired. Though the price asked for them is low, we are inclined to say, from the description, that they would be dear at any price at all.

CRYSTOLEUM.—A. M. SMYTHE says: "I should be much obliged if you will kindly inform me where I can obtain paints and instructions for crystoleum painting."—There used to be a Crystoleum Company in Regent-street that taught that kind of colouring, and supplied the necessary materials, but whether it is in existence now or not we are unable to say. The so-called crystoleum painting practically died out some time ago, and we doubt if any one practises it now. Ordinary colours, as supplied by artists' colourmen, are all that are necessary. The method has frequently been described in our back volumes and ALMANACS.

STEAMING SLIDES.—R. NORRIS complains that he is troubled with his slide becoming covered with moisture when put into the lantern. He says: "I hired a number of fine slides to show at an evening party, and directly one was put into the lantern it became covered with dew and quite spoilt the show. I have never seen this at public entertainments. How is it avoided?"—The reason was that the slides were cold, and the moisture in the room, heated by the lantern, condensed upon them. If the slides are kept in a warm place for a few hours before the show, so that they become warm, no moisture will condense upon them; thus the trouble will be avoided in the future.

PLATINOTYPE.—H. B. COLLIS asks: "Can you tell me what is the matter with enclosed platinum print? It was finished and produced in the usual manner, as far as we know, and has since been in a frame, and has become, as you will observe, very much eaten away in some manner. Can you account for it in any way?"—We cannot, as we have never seen the like before. It looks very much, however, as if moisture had been in the frame, and the print pressed on the glass and then become dry and cemented to it, so that, when separated, portions adhered to the glass. That is the only suggestion we can make, and it is noteworthy that the paper where there is no image is also affected.

SPOTTY PRINTS.—T. J. writes: "Enclosed you will find two photographs, which I shall be pleased to have your opinion in reference to the fading of one. This has been done about four years. I have prints done at the same time on other mounts, and not mounted quite as good as the one sent just done. Do you think it is the cause of the mount, or the fault in the fixing and washing? I have photographs done by me twenty-five years ago, as good now as when they went out. I shall be obliged if you will give me your opinion."—It is impossible to say definitely the cause, but it looks more as if the fault lay with the fixing than with either the mounts or the washing. We form this opinion from the appearance of the small spots and the general fading of the image.

GRANULARITY IN ENLARGEMENTS; FORMULÆ.—ARGUS S. CROYLE asks: "1. Will you be good enough to inform me of the best means of avoiding the appearance of 'grain' when making enlarged negatives? I find that using photo-mechanical plates for the transparencies and ordinary plates for the enlarged negatives the grain is very conspicuous. 2. Also would you be good enough to inform me where I can find Mr. Wellington's formula for developing, intensifying, and fixing in one operation; and what proportions of silver solution, hypo, and bromide to use in making Mr. Bolton's developer for the same purpose?"—1. There should be no conspicuous grain shown in this method of working beyond that existing in the original negative. If that be granular, of course the grain will be magnified in the enlargement, and the greater that is the more conspicuous it will become. It may, however, be somewhat mitigated by making the enlarged negative very slightly out of focus. 2. See Mr. Bolton's article in last week's JOURNAL.

VARIOUS.—ROBERT J. BENGHIAT (Smyrna).—As I find "Correspondence" the most important article in THE BRITISH JOURNAL OF PHOTOGRAPHY, I beg you to give me some hints on the following: 1. What must I do to prevent the cracks caused to albumen prints, when covered with water colours and dried? 2. To what does the index on the sixth page of the SUPPLEMENT TO THE BRITISH JOURNAL OF PHOTOGRAPHY of the second number refer? 3. What is the easiest way to prepare "flexible supports" for using as collotype plate? How to make the film? And please tell me the proportions for the preparation in Continental Weight System? 4. What is the use of the formula under the name of "Dusting-on Process" mentioned on page 180 of the ALMANAC?—In reply. 1. Use less gum with the colours. 2. The index to the volume for last year. 3. Parchment paper is sometimes used as a flexible support in the collotype process. We should advise you to get Schnaus's work on the collotype process, which you can obtain from Penrose & Co., Upper Baker-street, W.C., as space is too limited to describe processes. 4. To produce pictures by the dusting-on or powder process.

CARBON C.C.—J.A.H. says: "Thanks for reply in answer to my query in your Answers to Correspondents' column. I wish to ask you a few other questions, if you don't mind answering them in the same manner, viz:—1. I have printed a lot of carbons from Elliott's tissue single transfer process without the safe-edge, and I have had no frilling at all, nor any signs of any. Can you explain this, as the makers say it is imperative you should have it? Would it have made any difference if it had been double transfer? 2. There was an advertisement in your paper the other week which ran: 'Wanted, printer, to print C.C. and platinum.' In this instance what would C.C. mean, as it could not mean platino-type paper? 3. What is the difference between gelatino-chloride paper and collodio-chloride paper. 4. Give me the names of some collodio-chloride papers and makers' names?"—1. You were fortunate, but probably there were too deep shadows at the margins of the prints. Had you been working by the double transfer method, the result might, however, have been different. 2. Collodio-chloride paper was meant. 3. In the one case gelatine is the vehicle holding the silver chloride; in the other it is gelatine. 4. The Paget Dry Plate Company, and some comes from Germany.

REVERSED NEGATIVES.—DUDLEY KIDD says: "I am sorry that I did not give you my name and address last week, but it was unintentional and the result of an oversight. To save you the trouble of turning to my previous letter, I may state that I wanted to know where I had gone wrong in trying to get reversed negatives according to the plan suggested, I believe, by Bolas. I have taken ordinary dry plates and sensitised them in bichromate of potash solution of strength varying from one ounce to the pint down to half a drachm to the pint, and, after drying in the dark, have exposed these plates under a negative of medium printing density to light. The exposure has varied from a few minutes in the shade to hours in sunshine, in all cases seeing that an image was visible at the back of plate. In some cases only a faint image was produced, in others a deep effect. The bichromate was washed out under the tap for a few minutes, and in some cases even up to twenty-four hours' washing was given in frequent changes of water. The washed plates were then exposed to light, in some cases after drying and in other cases without a preliminary drying. The exposure was varied from a few seconds up to hours. The developer used after this was pyro-soda, pyro-ammonia, rodinal, and metol. Yet in no single case could I get sufficient density without a veiling of the parts of the negative which should have been clear. In no case could I get a printable negative. I forgot to mention that the plates were soaked in the bichromate solution for a period varying from a minute to five minutes. Would you kindly let me know (1) where I have gone wrong; (2) where I can get a full account of the process?"—1. You seem to have exposed the plates to light after the image was printed, and also not partially removed the bichromate before drying as directed by the author of the method. 2. Mr. Bolas described the process in a paper he read before the Photographic Society, June 8, 1880, which will be found on page 376 of our volume for that year.

## EX CATHEDRÂ.

THE Annual General Meeting of the Royal Photographic Society will be held at the Society's Rooms at eight p.m., on Tuesday, February 14, 1899, when the Report of the Council and the Treasurer's accounts will be submitted to the members, and the result of the ballot for the election of officers and Council will be announced. General business also will be transacted.

\* \* \*

THE balloting paper for the election of officers and Council of the Royal Photographic Society for 1899–1900 was issued last week. As it reached us simply in right of membership of the Society, we do not feel justified in publishing it *in extenso*, and we trust to find that we are not alone in treating the document as a private one. Many things concerning the internal management of the Society have from time to time found their way into print, and not only has this failed to operate to the advantage of the Society, but offence has been given by the publication of proceedings which have been rightly looked upon at the time as inadmissible for mention in the columns of

the press. For these reasons we simply content ourselves with a repetition of the recommendation, already given for the guidance of members at a distance, to vote for those of the old Council who are standing for re-election plus those nominees who, of the remaining candidates, have received the largest number of nominations.

\* \* \*

A GLASGOW correspondent informs us that there is considerable local dissatisfaction with the arrangements for the Photographic Section of the Glasgow International Exhibition of 1901. The constitution of the Photographic Committee, we learn, is giving widespread dissatisfaction, and already the West of Scotland Amateur Photographic Association have decided to have nothing to do with the Exhibition. It looks, adds our correspondent, as if there were going to be too much "Linked Ring" about the Exhibition, and he is of opinion that a mistake was made in appointing a professional photographer as Convener of the Committee—a post which ought, he thinks, to be given to a non-professional photographer, as was the case in 1888. There is already a distinct feeling, he tells us, that any one desirous of photographing inside the Exhibition buildings should be allowed to do so on payment of a nominal fee for the privilege, and that no sole right should be let to any one in particular, and in his opinion this will be a sore and difficult point to settle. It is to be regretted that dissatisfaction with the proposed arrangements for the Photographic Section has manifested itself; on the other hand, the circumstance that two years have to pass before the Exhibition will be opened supplies plenty of time and opportunities for the removal of all causes of local discontent. It is to be hoped, in the interests of the adequate representation of photography at what promises to be a great Exhibition, that harmony of feeling on the subject will shortly prevail.

\* \* \*

WE are informed that a meeting is to be held on Tuesday, February 21, at four o'clock, at the Midland Grand Hotel, St. Pancras, of a few friends who are interested in the ancient and decaying buildings in and around London, with a view to discussing informally the possibilities and best methods of securing pictorial photographic records of these objects of historical interest (which are constantly changing and dis-

appearing) to add to the National Photographic Record collection at the British Museum. Sir J. Benjamin Stone will be in the chair.

\* \* \*

Two more serious accidents have to be placed to the debit account of acetylene. The first occurred on the 31st ult. at a colliery near Ashby-de-la-Zouch, where, as the result of an explosion, the roof of the building containing the gas plant was blown out and the place wrecked, the man in charge of the gas plant being instantly killed. The second accident occurred on Thursday, February 3, at the brickworks of Messrs. C. J. Sanders & Co., near Chesterfield, and by which Mr. W. F. Richmond, M.I.M.E., of the firm of Richmond, Stockton, & Co., Staffs, and a workman were injured. It appears that, for the purpose of working night shifts, a large acetylene gas-making plant was being installed by Messrs. Richmond. On Thursday night an awful explosion occurred within the gas-holder, the great iron apparatus being hurled aloft, tearing away in its course the whole of the roof and iron-work above. The huge iron tank, roof, and other portions of the machine and building were blown thirty feet into the air. Mr. Richmond and a workman were buried beneath the fallen ruins, sustaining injuries to the head and shoulders, not, however, of a serious nature. Eight or ten other persons had narrow escapes. The accident is described as a remarkable one, as the gas-holder had been emptied as far as practicable, and the view of the vast column of white flame extending skywards, accompanied by the falling *débris* and water, is described as a beautiful though terrible sight. The new illuminant has already exacted a heavy toll in lives since its introduction a few years ago, and the accidents it has caused probably outnumber those from the use of compressed gases, which have been employed for a variety of purposes for a much longer period.

\* \* \*

WITH reference to our remark last week that the new Langfrier studio in Bond-street was probably the only one in London having a lift for the convenience of sitters, Mr. Fall, the well-known photographer of Baker-street, kindly writes to remind us that there are several London photographers having elevators on their premises—The London Stereoscopic Company, Regent-street; Messrs. Barraud; Messrs. Walery. Mr. Fall adds the interesting item of information that, generally speaking, visitors prefer stairs to lifts.

\* \* \*

MESSRS. ELLIOTT & SON, of Barnet, inform us that they have just completed some very extensive enlargements and improvements at their works to meet the increasing demand for carbon tissue. These include a large new coating room, fitted with the most complete machinery for coating and cutting tissue, grinding pigments, &c. With these additions and improvements Messrs. Elliott will now be able to more than double their present output of tissue. For months past their men have been working almost night and day, while, as regards the carbon enlarging department, the last month has been the busiest January Messrs. Elliott have ever had. We congratulate Messrs. Elliott on their enterprise and the success with which it is meeting—a sure sign of the firm hold which the beautiful and stable process of pigment printing has obtained upon photographers and the public.

WE are informed that the Tella film camera having proved such a great success, Messrs. Adams & Co. have sold the patent rights to the Tella Camera Company, Limited, who will shortly open convenient premises at 110, Shaftesbury-avenue, with a full stock. Agents will also be appointed throughout the country, and other steps will be taken to further popularise this well-known and ingenious instrument. The cameras will also, of course, be obtainable through Messrs. Adams & Co. as usual.

\* \* \*

THOMPSON & LEE, Close Works, Newcastle-on-Tyne, is the name and address of a newly established firm of technical photographers, who propose undertaking every description of photography for trade purposes—architecture, machinery, shipping, photo-mechanical printing for book and catalogue illustration, stereoscopic, lantern, and general work. They will make a speciality of producing photographs for reproduction as advertisement and catalogue illustrations. The firm starts with a well-equipped plant and every facility for making high-class photographs. Both partners are well-known members of the Newcastle Photographic Association, and have between them secured over fifty medals and awards; in particular, the name of Edgar G. Lee is of world-wide celebrity in connexion with excellence of photographic production. The young firm has our best wishes for its success; there is always room for good workers in photography.

\* \* \*

WE are sorry to read in the last issue of *Process Work and the Printer* that its publishers have deemed it advisable to terminate its existence with the present number. The reason given for this step is that it is felt that the trade comprised in the term "process work," to which the journal has chiefly appealed, is not sufficiently large to support a well-got-up journal with its incidental expenses. *Process Work and the Printer* was always a helpful and delightful publication. The articles were invariably judiciously chosen, and these with the very fine illustrations combined to make the publication of the highest use to those interested in phototypic reproduction processes. We are pleased to learn that *Process Work*, formerly issued by Messrs. Penrose, and which was merged into the defunct publication, will again make its appearance under the skilful direction of Mr. William Gamble.

#### THE PURIFICATION OF BENZOLE AND METHYLATED-SPIRITS WITH POTASSIUM PERMANGANATE.

WE quoted in our recent issue from a Continental source a method of deodorising benzole in which permanganate of potash is utilised, and some years ago we are reminded that a similar process was published in one of the English chemical journals for the purification of ordinary methylated spirits, while, on the introduction of the "mineralised" spirit, our contributor, Mr. W. B. Bolton, attempted similar means for rendering that preparation fit for ordinary photographic purposes. On that subject Mr. Bolton writes as follows:—

"Referring to the paragraph in the JOURNAL on the deodorisation of benzole by means of permanganate of potash, I should like to ask some of our qualified chemists whether what remains after such treatment is benzole, pure and simple. I have not tried the experiment in pure benzole, and am just now

not in a position to do so, but, just before the Excise blessed us with mineralised methylated spirit, I applied that treatment to mixtures of ordinary spirit with common benzoline, and also to benzoline alone, and, while it certainly improves the smell, I question whether it leaves the liquid otherwise as it found it. If half a teaspoonful of crystal of permanganate and a little water be mixed with benzoline and well shaken at intervals, a brown jelly-like precipitate is formed, and in time the whole lot becomes semi-solid, and acquires a rather pleasant smell in place of the original 'stink.' Very many years ago, when we used indiarubber solution as a substratum for dry-collodion plates, there were two solvents in general use, both of which were sold for glove-cleaning and general grease-removing purposes, namely, 'benzine collas' and 'Sherwoodale.' The former possessed all the nauseous pungency of the strongest mineral naphtha, the latter had a rather pleasant smell, not unlike that produced by permanganate; but the point I want to specially note now is that the presumably 'purified' sample did not possess half the solvent power of the others."

With regard to the action of permanganate on alcohol, Mr. Bolton further says: "So far as methylated spirits is concerned, there is not the least doubt that treatment with permanganate of potash converts it slowly, and not very slowly, into a variety of other substances, of which aldehyde and acetone are probably the principal, and as soon as I have a chance I mean to try if I can't develop a plate with 'methylated' so converted. I once recommended that treatment for purifying methylated spirit (not mineralised) for emulsion work, but I forgot that I applied a further process, namely, 'sunning,' in the presence of a small quantity of silver nitrate. If the purest alcohol obtainable be treated with permanganate, and then submitted to the test of boiling with nitrate of silver, as in sensitising a collodion emulsion, it will blacken most hideously, whereas before that treatment it would remain quite clear. Permanganate may be a grand 'purifier' for some purposes, but I think its functions, when applied to some substances, do not stop there."

#### UNANSWERABLE QUESTIONS.

THOSE of our readers who look through the column devoted to Answers to Correspondents must often be impressed with the number of queries that are put in reference to spots, stains on, and rapid fading of, silver prints, and also the apparently indefinite replies sometimes given. We say indefinite, for it is absolutely impossible, from the data usually furnished, to give anything else. Frequently the query is simply worded, "Kindly tell me in your next the cause of the spots on enclosed prints. Thanking you in anticipation." In another it may, in addition, be, "Is it the paper or the mount?" "I use So-and-So's paper and such-and-such a toning bath, and my printers tell me they take every care." "Do you think my boy neglects the washing?" "Is it the fault of the hypo?" &c. From such meagre information it is utterly impossible, in eight cases out of ten, to locate the precise cause of the trouble, because there may be half a dozen or more sources of it, while the results will be similar in appearance.

We could, however, generally give a definite reply in a single word, "Carelessness," which might, however, often be qualified by saying, "or lack of knowledge of the theory of the reactions that take place in the different operations in producing silver prints." Either reply, directly given, would,

no doubt, be, though true, unpleasant to the querist. Of course, if we, or any one else having the requisite knowledge, were to see the prints produced, we should at once be able to explain the cause of the trouble.

It is a curious fact that the larger majority of these queries are received from professional photographers, who, one would have thought, could, by overlooking the work while in progress, detect the cause of the trouble much better than any one else could by merely looking at a finished print or two. If they cannot, or do not, there seem to be only two reasons why. Either they do not possess the requisite knowledge, or that they are too negligent of their own interests to do so, for it must be obvious that spotty and fading prints, with the photographer's name attached to them, are by no means a desirable advertisement.

Oftentimes prints are sent with yellow stains upon them and the cause asked for, while it is obvious that they arise from the prints being allowed to stick together while in the fixing bath, the impress of other prints being palpable upon them. Yet the cause does not seem apparent to the querist. In such a case as this a definite answer can be given, and the precise reason located; but, if there is no definite impress of other prints, and similar stains may be caused by such things as the use of too weak a fixing solution, too weak to begin with, or exhausted by too many prints being fixed in it, being too cold, the prints being removed too soon, &c., the case is different. Therefore, how is it possible to say, by simply looking at the finished and mounted prints, which is the precise origin of the stain or its after-appearance when mounted. The only definite answer that can be given is "Carelessness."

With regard to spots, there are still more causes that may bring them about, all of which are avoidable with a knowledge of the principles involved and care in the manipulations. The most generally suspected cause of spots, stains, fading, &c., is the mount, the real cause, the manipulations, rarely being questioned. Even were the mounts in fault, the word "carelessness" would apply, because it behoves every photographer who values his reputation to take care that the mounts he uses will have no deleterious effect upon the prints mounted upon them. We should test them before taking them into use. It is a very simple matter, requires no chemical knowledge, and the method of doing it has, over and over again, been described in the JOURNAL, as well as in the ALMANACS.

Frequently nowadays the printing is intrusted to inexperienced lads and girls, often taken as apprentices, with a premium, or for a term without salary, while the master himself often has not the requisite theoretical knowledge to teach them the principles involved in producing satisfactory and lasting results. At one time photographic printers had a sound and well-grounded knowledge of their work, and were paid good salaries. Now the chief qualification of a printer, in many cases, seems to be simply the number of prints of good—at the present—appearance he can produce per day at a low wage. Hence the work is nowadays relegated, as we have just said, to lads and girls who are totally ignorant even of the fundamental principles involved in the work, and without the supervision of any one who is better informed. In these circumstances there is little surprise that trouble arises.

A few weeks back, it will be remembered, we directed attention to the difference there was between the robust constitution of the silver print of old and the more delicate ones of to-day by reason of the conditions prevailing. Here it

may be mentioned that in the old days the printing was looked upon as a very important part of photography; but, now that, by reason of the conditions prevailing, we have a more tender image to deal with, which requires greater knowledge to enhance its stability, the work seems to be mostly intrusted to inexperienced hands.

In this article we have spoken somewhat plainly, possibly unpleasantly, to some, though we hope not, but we have done so in the interests of our readers and of photography, for the impression is rapidly gaining ground that all photographs necessarily fade after a few years, and, unfortunately, it is in many cases only too true.

### AN ILLUSION AND ITS CAUSE.

An article by Mr. R. McCreary, in "Popular Astronomy" (THE BRITISH JOURNAL OF PHOTOGRAPHY, p. 40), seems to have excited a considerable amount of interest, judging from the frequency with which it has been copied into various periodicals. Briefly stated, he saw the sun set behind a building some distance away, which building he knew to be fifty feet long, yet it did not hide the sun. Why should it? The sun was further off certainly, but it is equally certainly more than fifty feet across. It is a simple question of relative appearance, which is, as all experience teaches us, most liable to erroneous conceptions. The whole question is an old one, and has a special interest to photographers, for there are few who make cloud studies who, in putting in a sun or a moon, do not make egregious errors in this very direction. The moon or the setting sun is almost always represented on too large a scale.

It is true that the moon, seeing that the angular measurements of sun and moon are practically identical,—one orb answers as well as the other,—always appears larger when near the horizon; but the effect is physiological, and not optical, and it at once disappears if the orb be viewed through a piece of paper rolled-up telescope wise. It would be an excellent object-lesson for any photographer contemplating putting a moon into a lantern-slide picture, for example, to wait till he next saw a full moon, then to hold at arm's length some circular object just large enough to cover the moon and hide it. It will surprise most of our readers to know that such object is not, as would be generally supposed, a dinner plate, but a good-sized seed pea! Slide-makers, take note.

**Secco Films.**—Under this name a recently formed Company, in Berlin have placed on the market a new film, which, from all accounts, is a bromide emulsion, coated on paper which has been previously coated with collodion. The films are treated in the ordinary way, but to the last washing water a few drops of glycerine are added, and the film soaked in this and then brought into contact with a "strengthening film," which is also soaked in the water and glycerine; the two are squeezed into contact and dried, and the papers stripped off. The strengthening film is nothing more than paper coated with collodion, so that the final result is the image-bearing film, enclosed between two films of collodion. They are said to be twenty-five per cent. cheaper than plates and fifty per cent. cheaper than colluloid films.

**Uranium Toning.**—M. L. P. Clerc recently read a paper before the Société Française de Photographie in which he states that there are two ferrocyanides of uranium and potassium, one of which is quite soluble in water and which only precipitates after standing some considerable time; the other insoluble in water, but

soluble in alkaline carbonate, sulphocyanides, and alkaline ferridcyanides. When a silver print or negative is placed in a mixture of ferridcyanide and a uranium salt, ferrocyanides of silver and uranium are formed; the former is white and opaque, and the latter coloured, and, if the uranium salt is in excess, the colour of the latter is brown; but, if the ferridcyanide is in excess the colour is red. In order to obtain the brown image, solutions of ferridcyanide of potassium and nitrate or acetate of uranium should be made up of equal strength and mixed in the proportion of ferridcyanide 50 parts, acetate 75 parts, or nitrate 90 parts. If the red colour is wanted, then the proportions should be ferridcyanide 50 parts, acetate 60 parts, or nitrate 70 parts. Sepia tones may be obtained with great ease by merely weakening the bath, and M. Clerc states that in all cases one per cent. of the salt is the best strength. It is always advisable to wash in water acidulated with about  $\frac{1}{20}$  acetic acid, and, should on drying the whites of the print become stained, this stain can be instantly removed by plunging the print into water heated to 60°, which will instantly dissolve the gelatine where there is no image, but leave the image intact.

**Dr. Burckhalter's Device for Photographing the Corona.**—The astronomer who writes in the *English Mechanic* over the signature "A Fellow of the Royal Astronomical Society" gives an account in a recent issue of the complete success attending the use of Dr. Burckhalter's mode of photographing the whole of the corona at one operation. The principle of the device consists in so graduating the exposure, during the stage when the sun's disc is wholly covered by the moon, that the various zones of the corona, with their differing degrees of actinic intensity, should be so alternately screened and exposed, in the exact proportion of their brightness, that in the completed exposure no part should be either over or under-exposed. Dr. Burckhalter writes that his method was tried by the Pierson expedition to Wangi in the Deccan during the total eclipse last year, and the result was a perfect negative. "As I write there lies before me a beautiful photograph of the solar corona with most delicate hair-like rays visible even in the paper print. I have no doubt that in the original negative there must be a marvellous amount of detail shown." So writes the F. R. A. S.

**Liquid Hydrogen and Crookes' Tubes.**—Professor Dewar, in his lecture at the Royal Institution last Friday fortnight, again showed the advantages of liquid gases for the ready production of a vacuum suitable for, if not, indeed, of too great tenuity, the ready making of Crookes' tubes. A closed tube is immersed in liquid hydrogen, and immediately the air solidifies and falls to the bottom; if the tube were so arranged that the part containing the accumulation of solid air could be sealed off, the other portion would, according to Sir William Crookes, have a vacuum of only one ten-millionth of an atmosphere.

**The Constitution of Incandescent Gas Mantles.**—All experienced in the use of gas mantles are aware of their different quality at the present time compared with that of a few years ago. This is largely owing to the different proportions of the rare earths employed in making the mantles. The translation of a paper by Herr E. Hintz on the subject is given in a recent number of the *Chemical News*, and from it we learn that the proportion giving the highest light effect is as follows: Thorium-cerium (99 per cent. thorium, 1 per cent. cerium oxides), 95 parts; 5 parts didymium. In recommending the use of incandescent gas burners for photographic purposes, one most important quality of their light, though familiar enough to those who have used the light for any length of time, is quite lost sight of by photographic writers. We allude to the fact that, with a given rate of pressure of gas, the luminosity exhibits a gradual, continuous falling off. The extent of this is referred to in the article we quote from. Thus a certain mantle giving 17 Hefner units at first, with a consumption of 115 litres per hour, gave, after 800 hours' burning, no more than 7.5 units at virtually the same rate of gas consumption. Another

mantle, of different composition, gave a drop from 40 to 27 units in 400 hours, and to 22 units in 800 hours; and a third gave 54, 38, and 32 units. It is quite evident that, with such conditions as these obtaining, the assertions as to the so-called certainty of exposures will have to be modified.

ANOTHER point in the use of gas mantles may be referred to. This is that, except in the very newest pattern of chimneyless burners, the pressure of gas at the burner must be adjusted with the utmost nicety. The least excess of pressure, and the light is diminished greatly.

**Making Wood Fireproof.**—Dr. C. J. Hexamer recently read a paper before the Franklin Institute describing a simple method of carrying out this object, which should be of the greatest use for those interested in the construction of photographic studios. The method was designed for the purpose of being utilised for the woodwork of vessels of war, but it is evident that it would be equally useful for any other place where fireproof woodwork was desirable, and in none would it be more useful than in studios, which, under existing rules, have to be weighted with such extravagantly heavy premiums for fire insurance. Stripped of explanatory context, Dr. Hexamer's method is very simple. The wood is first dried in a specially strong and tight chamber, which is afterwards exhausted of air; after this a solution of water glass is sprayed into the chamber, which causes a thorough impregnation of the pores of the wood. Finally, a solution of chloride of ammonium is injected into the cylinder, and a pressure of ten atmospheres applied. The result is the deposition in the innermost pores of the wood of gelatinous silica, which causes almost a petrification, and renders the wood as unflammable as stone.

**The Properties of Aluminium.**—M. A. Ditté, at the Paris Academy of Sciences, recently referred to the belief that aluminium is a metal which resists the greater number of chemical reagents. M. Ditté finds it otherwise. When the metal is placed in dilute acid, it dissolves rapidly at first, but a layer of gas is deposited on the surface, which resists further action. This layer adheres with the utmost firmness to the metal, but, when got rid of by reducing the atmospheric pressure or otherwise, the metal dissolves entirely. A solution of common salt acts at first, but produces an insoluble deposit of  $\text{Al}_2\text{O}_3$ , which arrests further action. The same thing occurs with salts of the alkaline earths—in fact, M. Ditté's experiments go to show that almost all chemical agents have an action on aluminium.

**Death of Herr Müller.**—It is with regret that we have to record the death of Herr Max Müller, Professor at the Technical High School at Brunswick and author of a well-known book on photography with magnesium.

#### ON THE DETERMINATION OF THE FOCAL LENGTH OF A COMPOUND LENS.

THE recent Traill-Taylor lecture, with its description of the focometer invented by Mr. Dallmeyer, have led one of your correspondents to make inquiries about getting one of these instruments for use; I think it may therefore be desirable to consider the question which heads this paper from the practical point of view of a working photographer.

To begin with, I may at once say that it does not seem to me that any practical want of a photographer involves an accurate knowledge of the focal length of his lenses; and that, however ingenious an apparatus may be, it is of little use to him unless the cost be very moderate and the facility in use be very great. A photographer rarely needs to determine the focal length of a lens for himself, and an expensive apparatus is valueless to him; valueless because the cost would have to be added on to that of the few lenses for which he would use it, and still more because a familiarity with the apparatus, and its being in working order, are essential to obtain good measures. To ensure these preliminary

conditions for good determinations will require an expenditure of labour and thought quite out of proportion to the results. It is a common delusion that by purchasing refined apparatus an untrained person can at once obtain results of great accuracy. It would be as reasonable to expect that, by supplying a ship with all the best navigating appliances, one could ensure a safe voyage with a crew of landmen. The truth is, that a trained man with the simplest means produces better results than the most refined means would give in unskilled hands. From this cause Mr. Dallmeyer's focometer is not a suitable apparatus for the photographer, whether he be amateur or professional. It is meant for the optician, and its especial province is to determine focal length in certain cases where other previous instruments failed. The practical photographer has only to deal with one case, which is manageable by well-known methods, that is, the determination of the focal length of such lenses as are used in the camera. Such lenses, from the very nature of things, are, as a whole (and it is only as a whole that the photographer has to do with them), what are called by opticians *positive lenses*, and it is quite possible to acquire such a knowledge of their focal length as is needed for ordinary purposes, without any apparatus more elaborate than a pair of compasses and a divided scale.

First, there is the method sketched out by Mr. Welborne Piper in your ALMANAC for this year. As he only gives the formula, perhaps I may be allowed to describe the determination of the focal length of a Cooke lens as an example of the actual working.

Having fixed my lens on the camera, I focussed carefully on the spire of a distant church at the centre of the ground glass (the axis of the lens having been adjusted to coincide with this centre), and a scratch was made on the fixed part of the baseboard where it was crossed by an appendage of the movable portion; this mark may be distinguished as A. A printed card was then clamped between the top and bottom of a box, and the camera so placed that, when the image of a letter was brought into focus on the ground glass in two positions, at different distances from the lens, it would occupy the same place on the ground glass. This is done by making the height of the camera, when level, suitable, and then choosing the letter to be focussed at both positions. If the camera be firmly clamped, the two positions of the object will necessarily be in

the line of the axis, and the two positions were marked, and also the corresponding places of the focus as shown in the same way as for mark A. Calling these two marks B and C, I proceeded to measure the distances, AB and AC, with compasses and a well-divided scale, and found them to be 4.290 inches and 1.812 inches, also the distance between the two marked positions of the card was 570.3 millimetres = 22.46 inches.

$$\text{Hence } F = \frac{22.46 \times 4.290 \times 1.812}{2.478} = 8.39 \text{ in.}$$

I would now offer some remarks for the benefit of the tyro. It will be seen that I have made use of two units in my scales for measurement. This has simply been because the shorter distance could be more accurately compared with a scale in my box of instruments, whereas the longer distance was most readily determined by the use of a tape divided in metric measure. The object in each case is to get each measure accurately, but slightly more error can be tolerated in the longer distance; how much must be left to the discretion of the operator. Generally it will be found that a decimally divided scale will be most convenient for use, and that, of such, one metrically divided will be more convenient than the inch and its fractions. I should mention that this

procedure is available only in cameras where the focussing is done by moving the back. If the front carrying the lens is moved, the extent of motion,  $n c$ , must be added to the interval between the positions of the object.

Then, as regards focussing, probably every photographer thinks he knows all about it; but in this matter, when examining a lens of large aperture it will be seen that some precautions are not out of place. First, since no screen is perfectly flat, it is necessary to focus on the same part of it, and this is near the centre, where the axis of the lens should cut it. Next, a magnifying glass should be used, of a pattern which admits of the position being fixed when the grain of the ground glass is clearly defined and sharp. With the lenses of large aperture, now so general, and a well-lighted and defined object, it will sometimes be found that, when the eye is traversed before the magnifying glass, the image of the object seems to move slightly if compared with any recognisable grain of the glass. This is due to the image not being on the screen, and the error should be corrected by the usual means till the image remains fixed on the screen. Of course, care must be taken that any mark used for this purpose is on the ground surface of the screen, and is not merely attached to it.

I proceed now to describe another way of obtaining the desired end, which was recommended some years ago by, I believe, Mr. Dallmeyer himself. Make two marks on the ground glass of the camera screen, at the same height as its centre, and near the edges, but so as to admit of the focussing glass being used to examine them (on my half-plate camera I find that about 5 inches is suitable). They may be conveniently made on a strip of paper and fixed temporarily at the proper height, as this will allow of their being easily measured on the paper being withdrawn.

On a table put a large sheet of paper, and set it in front of a window commanding a view of some object in the horizon at a distance which is sharply defined, and focus it carefully in the centre of the screen. If there be no suitable object near the horizon, then the support of the paper and camera must be tilted till some suitable object can be brought into the centre for focussing and fixed in that position. Now, without altering the focus, move the camera round till the image of the selected object comes on one of the marks, and fix the position of the camera by a pencil line on the paper drawn along one of its edges, or preferably along a straight-edge carefully placed in contact with a side of the baseboard; then turn the camera, being very careful not to shift the paper, till the image coincides with the other mark, and again draw a line as before. In order to do this so as to have the lines conveniently placed on the paper, it may, and will generally, be desirable to move the camera bodily. This is unobjectionable if the object of reference be far enough off. The desirable positions for the lines is when they intersect near one end of the sheet, and can be made of some length.

We shall now have a sheet of paper with two lines on it, which by their inclination measure the angle through which the camera has been moved. Call the point of intersection  $c$ , and along the two lines set off equal distances,  $CA$  and  $CB$ ; join  $AB$ , and bisect it by a perpendicular from  $c$  to  $D$ , the centre point. Measure  $AB$  and  $CD$  carefully. Then  $f = a \frac{CD}{AB}$ , where  $a$  represents the distance between the two marks on the ground glass.

With the same lens as before, two marks were made on the ground glass of the camera, whose distance was found to be 4.93 inches. The distances,  $CA$  and  $CB$ , were each set off 300 mm., and  $AB$  was measured 167.1 mm., and  $CD = 288.3$  mm.

$$\text{Hence } f = \frac{288.3}{167.1} \times 4.93 = 8.50 \text{ in.}$$

It does not matter what the unit of measurement of  $AC$  and  $CD$  is, as we are only concerned with their proportion.

It may be thought that the difference of values I have found for the focal length of this lens is excessive, considering that the fixing of an object in focus is liable to far smaller errors than one-tenth of an inch, but it is to be remembered that only one end of the length is so determined, the other has to be deducted from the observations, and the errors inevitable in the measurements are multiplied in these cases, as in all such. It will take a good deal of care to get even such good results as above.

An apparatus like the focometer might be, with advantage, used with Mr. Piper's method, and would give more accurate results; but those above are good enough for the purposes of a photographer, who would do well, in case he wants better, to apply to some competent optician who has the needful apparatus and th to use it. J. F. T.

## THE THEORY OF THE GUM BICHROMATE PROCESS.

HERR BEHRENS publishes in the *Photographische Mittheilungen* an interesting paper on this subject. He first tried why it was not possible to use ordinary carbon tissue like bi-gum, that is to say, without transfer, and he ascribes it to the thickness of the film, which in the ordinary tissue is about 1.1 mm. thick, whilst in the gum-bichromate film it is only 0.025 mm. The ratio between the two is therefore about 400 : 9. The thick film cannot be therefore printed right through without the surface becoming tanned and insoluble, whilst, with the thin film, the half-tones even print right through, and thus adhere to the paper. An interesting experiment was made by Herr Behrens, as follows: He sensitised a sheet of bi-gum paper, and, after drying, folded it in half, so that the two films were in contact, and then made the upper paper transparent, and printed under a sensitometer. The light penetrated right through to the second film, and, on development, this showed only a few numbers below the upper film, so that enough light penetrated the first film to produce an image on the second. When the same experiment was made with a negative, two pictures could be obtained. He also noted that, during exposure, brown chromic oxide, which has strong tanning powers, was first formed, but that on longer exposure this was reduced to green chromous oxide, which has not such a strong tanning action; and, if the exposure was still further extended, a negative was obtained instead of a positive.

## ORTHOCHROMATIC PHOTOGRAPHY.

[A Paper read before the Sutton Photographic Club, on Thursday, February 2.]

ORTHOCHROMATIC, from *Orthos*, right, and *chroma*, colour; or *Isochromatic* from *Isos*, equal, and *chroma*, colour, as this particular process of photography is somewhat indiscriminately called, is so far misleading, in that colour, as such, does not enter into the matter at all; such terms would be more strictly applicable to that which scientists all over the world are striving to obtain, i.e., "Photography in Natural Colours." What is really meant, however, by these terms as at present applied, is a more exact, more true, rendering in monochrome of the colours of nature. Unfortunately it so happens that the colours which have the greatest effect on the eye have the least effect on the photographic plate, and the object of orthochromatic photography is, to quote Professor Meldola, "to bring visual intensity and photographic intensity into harmony." The coloured objects in nature, such as flowers, &c., and artificially coloured objects, such as paintings, coloured paper, &c., show in their different colours because they are only capable of reflecting certain portions of white light, and, if viewed by any other than white light, their colour appears to us to be altered. Thus, I have here a card on which are pasted four very distinct colours as we see them in daylight; but now, if I throw on to this card a sodium flame, the colours no longer appear to be the same as they were before, with the exception of the yellow, because there does not exist in this monochromatic flame any light vibrations to which they are capable of responding. Let me illustrate these light vibrations or wave-lengths in another way. I have here what is called a wave-slide (which I made for quite another purpose, but which will serve to illustrate this point), and you will see that, as it is moved along, a lot of waves in apparently progressive motion appear on the screen. You will also notice that one wave, which we may call the violet, appears to move twice as fast as the other wave, which we may call the red. In reality these waves do not progress at all, it is only an up-and-down motion, as you will notice by the coloured dots, the other effect being merely an optical one; but you will also see why the violet end of the spectrum is more active than the red end, the wave-lengths are much shorter and more rapid at the one end than at the other.

## HISTORICAL NOTES.

From this it is obvious that the problem we have to solve is not an easy one. In 1873 Professor H. W. Vogel, of Berlin, whose loss the scientific world has so lately had to deplore, made the first step in this much-desired direction, and, since then, numerous experimenters in England, America, Germany, France, and Russia have been continuing the investigation, among whom may be mentioned Captain Abney, Professor Bothamley, Dr. Eder, Mr. Ives, Mr. Cadett, Mr. Sanger Shepherd, Mr. L. Warnerke, MM. Lumière, and others. Those interested in the subject will find numerous articles relating thereto in *THE BRITISH JOURNAL OF PHOTOGRAPHY* and its *ALMANAC*, also in *Photography Annual*, where also may be found references to a great number of foreign papers, published in Germany and elsewhere. I give the following extracts in order to indicate what has been done in recent years with regard to this most interesting subject. In May, 1894, Professor W. K. Burton recommended a screen of gelatine (twenty grains to the ounce), stained with ammonium picrate; and, in November, 1895, the same author made some further observations on picrated gelatine for use as screens, and also for a safe dark-room light, but both he and Mr. Spiller pointed out that such a screen was not very reliable, owing to the action of the light

on the pierate. In May and June, 1894, Mr. E. J. Wall delivered two valuable lectures on Colour Photography at the Cordwainers' Hall, which were published in THE BRITISH JOURNAL OF PHOTOGRAPHY; he also made a translation of Dr. Eder's German work, which appeared in the pages of the *Amateur Photographer*. There is, unfortunately, no corresponding work in English. In November, 1894, M. Leon Warnerke read a paper on Chromatic Photography, referring specially to the plates issued about that time by the MM. Lumière, and which consisted of three series—i.e., A, sensitive to yellow and green; B, sensitive to yellow and red; and C, also known as "panchromatic," sensitive to yellow, red, and green. The author used a screen; the form to which he gave preference was a liquid filter (similar to the one I show you, and which I made for a demonstration given by myself to the Croydon Microscopical and Natural History Club in February, 1895) placed at the back of the lens. But that was not what the author considered the best way of using a light-filter, which was to place the filter in front of the source of light, be that daylight or artificial light, and to illuminate the subject itself with monochromatic light. In November, 1894, Captain Houdaille published a paper in the *Bulletin de la Société Française* on "Orthochromatism in Photography," in which he tested the sensitiveness of plates (he seems to have used Lumière's) to various reflected colours, preferentially to those given by a prism. He made preliminary experiments on the orthochromatism of the human eye, from which he deduces that white and yellow produce the same impression on the eye, green is more feeble, and red still more so. Taking 100 as the aggregate of the four colours, he found that the sensitiveness of the eye to the colours was as follows: white, 29; green, 22; yellow, 29; and red, 20. In testing plates he employed four varieties of light, i.e., sunlight and magnesium (which were similar in their action), petroleum flame, and flash powders. In conclusion, this author considers that it is quite possible to exaggerate the importance of orthochromatic emulsions, and states that an ordinary plate used with a screen is equal to series A plate without a screen. That an ordinary plate with four times the normal exposure is about equal to series B normally exposed; and that an ordinary plate exposed to a petroleum flame is nearly identical with series A exposed to diffused light. What some of our writers of the present day would say to such statements I do not know, but I doubt if they would be allowed to pass unchallenged.

In March, 1895, Mr. J. W. Gifford in a communication on "The Correct Values of Colours in Photography," remarks that pure spectrum colours differ materially from those seen around us in nature, and that hence, in order to do correct work, while the pure spectrum colours are absolutely essential, these must be supplemented by such other colours as we find in nature, in painting, in chromo-lithographs, and in coloured charts. He then proceeds to say that plates have been prepared which are not only sensitive to the blue and violet, but also to the green, yellow, and red, but still leave a gap in the green (we shall see presently how Mr. Cadett has attempted to supply this deficiency in his spectrum plate). To fill up this gap in the green, either a plate must be made which is sensitive to this particular region of the spectrum, or a screen or light-filter must be used to exalt the sensitiveness of the green and red, by weakening the effect of the other colours.

#### ABNEY'S "ORTHOCHROMATICS."

We now come to a very important point in the history of our subject, for, in June, 1895, Captain Abney, whose name is inseparable from orthochromatic photography, published a long and most valuable paper on "Orthochromatics." This paper was read before the Photographic Society of Great Britain (now the Royal) and printed in its *Transactions*, and is constantly quoted by writers on the subject. In this paper he points out that the problem is to obtain a negative which shall give to a monochrome print as correct values for colour and its shades as it will give in a reproduction of a black-and-white subject. Taking a chart consisting of the colours red, yellow, green, and blue, he proceeds to show what the luminosities of these colours are, and that it varies in a very marked manner according to the lighting. Again, these are not pure spectrum colours, inasmuch as they reflect other colours besides the red, yellow, green, and blue. Thus a complicated task is provided for us, and what we have to do is to find a suitable plate and screens which will give in a print these relative luminosities. Captain Abney then proceeds to work out these problems in a way that but very few could hope to imitate, and I must therefore refer you to his original paper. He, however, repeated and emphasised Mr. Cadett's remark in the discussion which followed the reading of the paper, as to the great importance of having carefully selected colour screens, and he thought that makers of orthochromatic plates should in future send with them a proper screen, as certainly the plate and screen must go hand in hand.

#### THE CADETT PLATES.

We now come to November, 1895, when Mr. James Cadett read a paper (which was published in February, 1896) on "Colour-correct Photography and a New Plate," in which, after referring to the work done by Captain Abney, Mr. Gifford and the MM. Lumière, he described his new plate, and showed, by means of slides on the screen, what its capabilities were both with and without a colour-filter. Replying to a question as to how

such plates were to be developed, Mr. Cadett stated that, having ascertained about the correct exposure, the plates could be taken out of, as they were put into, the slides in total darkness, and developed by time, and, if then it should be found that the density was too great, they could afterwards be reduced. Since Mr. Cadett read this paper, his firm have issued a "Safelight" by which inspection of the plates in course of development may be carried out; this glass only passed rays at the extreme A or red end of the spectrum, and was always tested before being sent out. Referring to the fact that MM. Lumière advised the use of a faint green light, Mr. Cadett stated that their plates were deficient in that very green light which was recommended. In the volume of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for this year (1899) will be found an article by Mr. Alfred Watkins on the development of these plates by time, using his eikonometer for the purpose. Mr. Cadett, replying to another question as to whether his plates were perfect without a screen said, No, the blue was still too great, but with a light yellow screen, such as an alkaline solution of potassium chromate, there was a practically perfect range throughout. In June, 1897, Mr. H. T. Malby read a very interesting and practical paper on "The Correct Rendering of the Colours of Flowers," and this gentleman has also prepared an Affiliation lecture, illustrated by lantern slides, on the same subject, so that those societies which have joined the Affiliation will be able to have the benefit of it. Mr. Malby, judging from his paper, does not appear to have gone aside to make screens, &c., but used the Ilford and Edwards plates, and the light and dark screens issued by them, and also the Burchett screen, with such flowers as daffodils, wild roses, narcissi, iris, and some orchids, so that, with such materials easily to hand, any one could repeat, and possibly extend, the observations made by him. In July, 1898, we have an important paper by Mr. Sanger Shepherd on "The Scientific Translation of Colour into Monochrome," in which the author, after stating what the object of orthochromatic photography is, goes on to say that the difficulties may be overcome in three ways, i.e., 1. To have a plate sensitive to the various colours. 2. To employ coloured screens. 3. To use a combination of both these methods. I shall have occasion to refer to both of these papers again presently.

#### SENSITISING PLATES.

I fear I have somewhat tired you by what I may call the chronological history of the subject, and so will pass on to more practical matters. Now, as you all know, there are plenty of plates on the market which are sensitised for the various colours. Edwards, Ilford, Lumière (who, by the way, have recently made a colour-sensitive film) and Cadett, are names familiar to you all. There are two methods of sensitising a plate, i.e., 1. To add the dyestuffs to the emulsion previous to coating; 2. To dip the ordinary plate into a solution of the dyestuff and drying it in the dark. The last operation could, without any great difficulty, be performed by the amateur experimentalist. What the precise nature of the action of these dyestuffs on the silver haloids is cannot at present be accurately stated. According to one theory (the physical) the light vibrations absorbed by the dyes are transferred to the silver salt, thus rendering it sensitive in the region of absorption; but, according to the other theory, the chemical, which has been made the subject of many experiments, notably by Dr. Eder and Captain Abney, there exists a sort of weak chemical union between the dye-stuff and the silver salt, and that this compound, whatever its nature may be, is decomposed by the action of light (Eder); or that the colouring matter undergoes photo-chemical decomposition, giving rise to products which act as reducing agents on the silver haloids; and, seeing the highly complicated molecules possessed by these dyes, it is not to be wondered at that, among the products of their decomposition, substances of a reducing nature should be formed (Abney). The chemical hypothesis of orthochromatic action rests upon the fact that the best special sensitisers are the most fugitive dyes. In this connexion it is interesting to note the special action of the spectrum colours on the silver chloride, which was noticed by Seebeck in 1810, Sir John Herschell in 1840, Becquerel in 1847 and 1855, and other observers, but quite recently by Carey Lea, whose work in this direction, in close connexion with that greatest of all photographic problems, i.e., photography in natural colours, was very ably reviewed by the Editor in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for this year (1899).

#### SCREENS.

Passing from plates to screens, which still appear necessary for obtaining the best results, we find that no less than five different kinds of screens are made or suggested, thus (1) a gelatine film with which has been incorporated the colouring matter to be employed; (2) a plain gelatine film which is soaked in a solution of the colouring matter, raised and dried; (3) a stained collodion film; (4) screens of coloured glass; (5) a liquid light-filter contained in a glass cell. I show you specimens of all five of these varieties; with the three first it is best to varnish them with a mastic benzole (sixty grains to the ounce answers very well). The dyestuffs employed are several, and consist mainly of the aniline colours, which are, as you know, derived from coal tar. Con-

sult Benedikt's "Chemistry of the Coal-tar Colours." I show you some of them from which the screens are prepared, i.e., aniline yellow, naphthol yellow, brilliant yellow, multiple yellow, aurine, chrisoidine, aurantia, malachite green and naphthol green; then there are two inorganic substances, i.e., the chromate and dichromate of potassium, together with picric acid, or its ammonium salt, which, however, as previously stated, is not altogether reliable if exposed much to the action of light. Now, when we get one of these dyestuffs, the first point to ascertain is what it is soluble in; if in water, it may be used either for colouring the gelatine previous to coating the glass, or for soaking the already coated glass in, and here I may state that either micro-cover glass, patent plate or thin lantern plates may be used, if flat and they do not distort the image; if the latter, fix, wash, and dry unexposed plates, and then soak them in the colour. With a water soluble dye, screens of various strengths of colour are easily obtained by taking several pieces of the gelatine-coated glass, putting them into a dish with the dye solution, and removing them at intervals, say of 1, 2, 4, 6, 8, 10, and 15 minutes. The specimens I have here are partly produced in that way, but most of them were made by taking a sheet of patent plate which was quite flat and almost colourless, carefully levelling it, flowing it with a warm solution of gelatine (twenty grains to the ounce answers well), previously filtered bright by the aid of a hot-water funnel, and covering it over with a large sheet of glass supported at some distance (three or four inches) above it, to keep off dust, &c., and allowing it to dry; when quite dry, it may be cut up into squares like these. These squares may be used in three ways, i.e., (1) the gelatine may be soaked in the coloured solution (gelatine has a great affinity for these colours); (2) the gelatine surface may be flowed over with a coloured collodion; or, (3) a combination of these two may be used, that is, the gelatine may be stained one colour, and, when dry, flowed over with a collodion of a different colour. Two such compound pieces I have here which, if bound together like a lantern slide, form a very safe dark-room light (Sanger Shepherd). If, however, the dye is not soluble in water, but soluble in spirit, then a collodion must be made of it, by dissolving it in a mixture of one part strong alcohol and two parts of highly rectified ether, filtering if necessary, and then dissolving a structureless gun-cotton (high-temperature cotton answers well) in the proportion of six grains to the ounce. The coloured collodion thus obtained, several samples of which I have here, may be flowed over the gelatinised plate, (thus), and, when dry, varnished with the mastic-benzole varnish (thus). Then we have screens of coloured glass, and these undoubtedly would be the most convenient if we could obtain glass of the requisite colour, which unfortunately we cannot at present. Several glass screens are, however, on the market, such as Ilford, Edwards, Carbutt, Burchett, &c., these last are made by Dallmeyer, and consist of two glasses, one a very light amber or orange yellow, and the other a light green; but Mr. Burchett states that the deeper the yellow the better the result, although, of course, the exposure has to be prolonged. Finally, there are the liquid, or ray filters, as they are called; one of these I show you made by myself in February, 1895, in illustration of a paper I read on "Orthochromatic Photography" before the Croydon Microscopical and Natural History Club, and which any one can easily construct for himself; and the Bausch & Lomb filter, in which a similar idea is carried out in a more complete and very much more expensive way. These filters can be used for any of the water soluble dyes (they must not be used for spirit soluble dyes), and Bausch & Lomb issue with theirs a solution of dichromate of potash; Mr. Cadett recommends a neutral or slightly alkaline solution of the chromate. A specimen of this filter I also show you. This class of filter, especially my simple, cheap, and easily made one, is convenient, because a number of liquid dyes can be rapidly experimented upon. I also show you a handy contrivance for fixing them in front of the lens, where they can be readily got at, and for the rapid changing of the cells. With regard to the strength of the solutions, either in water or collodion, so much depends on the intensity of the dye and the sensitiveness of the plate, but somewhere about from half (or even less) to two per cent. of the dye will probably be found to give satisfactory results.

In conclusion, the points to be remembered for the best rendering of colour values in photography are: 1. Use an orthochromatic plate; 2. Back the plate, if possible; 3. Use a colour screen or light-filter, which will generally be of a yellow or greenish-yellow colour; 4. Adapt the screen to the work in hand, that is, if a subject, such as flowers, is all one colour, say all red, or blue, or yellow, there will be little, if any, advantage in using a screen; but, if it be blue and red, or blue and yellow, or a mixture of all three colours, then a screen becomes necessary for suppressing the blue, and so giving the red and yellow time to act on the plate; 5. Give always a full exposure, by preference in a subdued light rather than sunlight; and 6. Develop in a solution weak in pyro, but strong in alkali (for some subjects half a grain of pyro to the ounce is ample), and so obtain a soft negative, full of detail, but with no harsh contrasts. I do not pretend to be in any way an authority on this subject, but have found much pleasure during some weeks in working at it, and give you my results simply in the hope that you may find as much interest in the matter as I have done. I will now put a few comparison slides (not beautiful pictures) on the screen, from which you will be able to form an opinion on the merits of orthochromatic over ordinary plates.

J. H. BALDOCK.

## PHOTOGRAPHIC SOCIETY LIFE.

BEFORE the London and Provincial Photographic Association, on February 2, Mr. Walter D. Welford read a paper upon "Photographic Society Life." He stated at the outset that his remarks were intended to be of a criticising nature, but in no way offensive, and the criticism was aimed at what he considered as possibly the worst phases of society meetings. He was of opinion that there were many things capable of improvement, and that without destroying the sociability of some or the business qualities of other societies, but for all that he felt that, the more our meetings tended towards the social nature, the greater the danger of abuses creeping in. To take the question of attendance; who made the Society or helped it along? he asked, replying that it was the regular attender. And yet the very fact of his being regular brought him very often within the scope of the proverb, "Familiarity breeds contempt;" for after a while people began to think less of him, as they got accustomed to his sayings. But let a member turn up who had not been seen for some time, and everybody wanted to know what he had to say. Instead of being received with open arms he should rather be fined for neglecting his duties, and yet he is often the man who, putting in an appearance after an absence of six months, is put in the chair. On the face of it he was hardly an efficient Chairman, although well and good if the Chairman be only a figurative expression. However, even such a man made a better Chairman than the one who argues for the whole meeting. The first, knowing nothing through long absence, says nothing if he be wise, but the other makes a point of arguing with each speaker, with the result that the meeting is a one-man show. Proceeding to another point, much has been said of late that lantern lecturing was on the decline. The reason was—photographic societies. To see the slides, and to hear upon what plate it was made, and how developed, was all they asked. Leave the descriptive matter to the missions, but show us slides. Personally, the lecturer was heartily tired of the way slides were pushed through the carrier one after another as fast as they would go, with a couple of words to describe them. In a word, he maintained that, although all slide displays need not be accompanied by a lecture, the further we got away from the disgraceful scramble, now so prevalent, the better for everybody.

Mr. Welford next emphasised the importance of absolute impartiality in the management of a Society. Everybody should be under one code of rules, whether he be President, Secretary, or an ordinary member. This is more felt when certain few members practically run the Society. This is often called a clique, but wrongly, he thought. However, in the sense in which the word was often interpreted, in many cases a clique was a positive boon. So long as it worked for the benefit of the Society, the clique was admissible; but, when it got at loggerheads with the membership, it became the very reverse. Mr. Welford then criticised the poor treatment only too often meted out to lecturers, especially in London. A provincial man, with perhaps a few friends of his own in the place, is left to find his way to the meeting-place alone, he receives a hearty vote of thanks for his trouble, the members file off home, and he waits about by himself for his train home. The speaker considered this a scandalous state of things, and that somebody should be deputed to look after the comfort of such lecturers, who, often at considerable inconvenience, made very long journeys to instruct a thoughtless class of men.

Mr. W. T. Wilkinson said that, as regards the latter part of the remarks, it was well known that Yorkshire treated its lecturers in a first-class manner, and he should like to see the practice extended more generally.

Mr. H. Vivian Hyde noticed that no mention was made of the treatment accorded to beginners in many of our London societies. He felt that this was a branch of the membership which should be catered for. The future of societies depended upon the influx of new members, and a little more encouragement extended to this class was highly to be desired.

Mr. Philip Everitt thought that, in the case of the plea for more descriptive matter at lantern displays, it should not be forgotten that very often it is the question of the development or exposure of the photograph shown that interests the members most, and he should never condemn a man for passing through his slides and stating the particulars he mentioned, or any other point of technical interest. As regards the status of the beginner, this Association, he thought, was in a very advanced position. The old custom of pouncing upon the raw beginner and holding him up to ridicule had happily died out. In a sense he thought there was more to be learnt from faulty work than perfect pictures. Cliques, he thought, were bound to occur, but he saw no objection to them as long as they were employed for good.

Mr. Mackie spoke to the effect that the treatment accorded to beginners was to a large extent dependent upon the attitude they assumed. To show a bad result for admiration was a sure means to invite ridicule, but he thought the beginner who brought forward his work with a view to acquiring better knowledge stood in no fear of such treatment.

Mr. Rapson, as a beginner, received much valuable help from criticism of his work in days gone by, and other speakers testified to the same effect. The discussion was a long and interesting one, though being almost wholly confined to the question of the beginner, a point not touched upon in the paper.

# ELEMENTARY OPHTHALMICS.

At the meeting of the Photographic Club on February 1, the Rev. F. C. Lambert gave a lecture upon "Elementary Ophthalmics."

Ophthalmics, he said, was a useful term to include those curious phenomena of the eye which are out of the domain of the surgeon or physician, and not essentially within the knowledge of the scientific optician. The subject was an interesting one to all people who took a reasonable interest in the world outside them; and in the use of their own eyes, and for the purposes of the lecture, he would assume that nobody present had knowledge of the subject, or at least had given it no attention. He regarded the eye merely as a dark chamber with a lens in front, and at the back a sensitive surface. The first thing that struck one was the well-known but little-realised fact that things were seen upside down. Proof of this could be had by performing a simple experiment in the following manner: A piece of brown paper, doubled to ensure opacity, should be pierced with a pin and held by one hand a short distance from the face in a line drawn between the eye and a lamp. With the free hand a pin, head up, is brought close in front of the eye, and, when it intercepts the beam of light, the shadow (not the image) is seen to be inverted.

Every eye, so far as is known, has a blind spot. This fact is one that is not so little known as how it happens and how to find it. If we were to examine an eye, we should find that exactly opposite the axis of the lens on the retina there was a depression. To one side of this—always on the side nearest the nose—enters the optic nerve, and it might well be imagined that the most intense sensations of vision would be where the nerve enters the eye; but, so far from that being the case, the point where the supply of nerve fibres enters the eye is the blind spot, caused by the presence of the artery which supplies the extremely fine blood vessels of the eye with blood. The region of acute vision is the depression mentioned, and it is this little spot with which we really see, the other portions receiving only a vague sensation of anything before the eye; in other words, the eye has to be directed full upon the object to bring it within critical vision. A practical method of showing the presence of a blind spot in the eye was to take a piece of paper, with two marks placed horizontally, two or three inches apart. Closing, say, the left eye, the left mark on the paper is brought opposite to the right eye, and the paper moved to and away from the face until the second mark disappears from sight, which will be when its image falls exactly upon the spot where the optic nerve enters the eye.

That there is an absolute physical limit to the size of an image which is visible is not common knowledge, but it is a fact, proved by independent experimenters, that the smallest image discernible by the retina never measures less than .001 of a millimetre. It at once occurs to you to ask how a distant star is recognised, in face of this rule; and the explanation is that the size of all luminous objects appears far greater than it should, caused by a kind of diffusion in the eye. Mr. Lambert then explained how the eye accommodated itself at will to the different planes before it. In a camera the accommodation is effected by altering the distance between the focusing screen and the image-forming lens. In the eye this is not the case, but the same effect is produced by the muscles of the eye, which flatten or thicken the lens, altering its curves and at the same time the point at which objects at a given distance come to a focus. That this was so was experimentally illustrated. In the course of the lecture many more phenomena were referred to—irradiation and other errors of judgment perpetrated by the eye—closing with a description of a simple device for reproducing Dalmayer's focometer, the practicability of which was there and then demonstrated.

# THE GUM-BICHROMATE PROCESS.

Mr. W. J. WARREN, President of the Leeds Camera Club, gave a lecture to the members on Wednesday, February 1, on "The Gum-bichromate Process of Printing."

Commencing by pointing out that this method of printing was suggested about 1850, Mr. Warren said it was allowed to fall into disuse, and some five or six years ago was revived by different workers, but chiefly by Messieurs Lefèvre, of Tours, and Demachy, of Paris. Its advantages were next dealt with, the power of control and of modification over results being emphasised. An ordinary drawing paper was sensitised with potassium bichromate, dried, coated with a mixture of gum and water-colour paint evenly on its surface, dried again, exposed to daylight under the negative, and then developed in warm water; the tissue not hardened by the action of the light washed away. By using a brush, any part of the image might be removed, or, by refraining from developing any section, it would be left in shadow. The processes of coating were demonstrated, and subsequently the lecturer developed several prints, using various means to modify the results at will. Afterwards some of the members tried their hands at development, and their efforts created an appreciation of the unique possibilities of the process. The lecturer then explained various modifications possible by the use of different papers by sizing with gelatine, starch, or arrowroot, and by various applications during development, and detailed the process of clearing and fixing, by first drying the print and then immersing in a five per

cent. solution of alum. Subsequently a number of prints, showing different results, with the same negatives, by M. Demachy, of Paris, lent, with his permission, by the editor of the *Amateur Photographer*, were handed round, and a number of questions answered. Mr. Warren finally pointed out that, whether the process he had explained be exclusively adopted by any worker or not, experiments with it would be an education on light and shade and true tone values, two subjects most important to monochrome workers in general and photographers in particular.

# LEVY-LAJEUNESSE APPARATUS FOR USING MAGNESIUM.

FIG. 1 is an elevation of the face of the apparatus shown open.

Fig. 2 is a transverse section following the line A—B of fig. 1, showing the arrangement of the apparatus on a suitably shaped foot which enables it to be adjusted at the height and inclination desired for the projection of the light upon the subject it is desired to photograph.

Fig. 3 is a transverse section following the line C—D of fig. 1.

Fig. 4 is a section similar to that of fig. 2, the apparatus being closed, that is to say, the shutters and the hammers occupy the positions which they take up when thrown out of gear and after the taking of the negative.

Fig. 5 is a fragment in plan, showing on a larger scale one of the cups for the reception of the magnesium powder.

The apparatus consists principally of a drum of cylindrical or other suitable shape in which there are placed small cups or bowls for burning the magnesium. The posterior end of this drum forms a reflector; the whole of the front face, which is uncovered before the operation, is formed of two movable shutters, which act as an obturator directly the flash is produced.

The combustion of the magnesium is effected by exploding caps by the aid of strikers the stroke of which is delivered simultaneously with the closing of the shutters and by means of one and the same disengagement or releasing mechanism. The said mechanism is actuated by the pressure transmitted to a spring by means of a simple pneumatic rubber ball which, if desired, could be made to control the shutter of the objective at the same time.

The fixed drum, 1, made of aluminium or other material—the inner surface being polished, plated, or coated so as to form a reflector—engages by means of the slides, 2, with the feet or branches, 3, of a tripod or stand which may be adjusted at the desired inclination at the head of the central supporting leg, 4, which slides into the tripod or support of the apparatus.

5 is the lower shutter, 6 the upper shutter, 7 is a cylindrical tube supported at its ends by two pivots, 8, attached to the side walls of the drum, 1—these walls forming the two bases closing the apparatus at its ends. The tube, 7, may be made to revolve with hard friction on its pivots; it carries fixed on to it, following one of its stops, a certain number of cups, 9 (shown in longitudinal elevation in fig. 1 and in plan in fig. 5). These cups are intended to receive the magnesium powder, and have in the centre a depression and points, 10, upon which a cap can be fixed.

In the centre of the tube carrying the cups there is fixed the end of a coiled spring, 11, wound round a rod, 12, placed parallel with the tube, 7, and on this there are fixed the hammers, 13, arranged opposite or over the cups, 9.

The said rod, 12, pivots on two small supports, 14, fixed to the tube, 7. The end of the recoil spring, 11, is fixed to this rod, which constantly tends to throw the hammers on to the cups, 9.

The lower shutter, 5, is governed from top to bottom by two springs, 15 and 15', fixed respectively at 16 and 16' of one of their ends to the lateral wall, corresponding to them, of the fixed drum, 1, and by their other ends to the arms, 5<sup>1</sup> and 5<sup>2</sup>, which form the lateral end walls of the shutter. These arms pivot around the shafts, 17, 17', fixed to the lateral walls of the drum, 1.

The upper shutter, 6, is governed from top to bottom by the springs, 18, 18', fixed respectively by one of their ends at 19 and 19' to the lateral walls of the drum, 1, and by their other end to the lateral walls, 6<sup>1</sup>, 6<sup>2</sup>, of the said shutter.

The shutter, 5, is engaged at one end by a staple, 20, and at the other by a hasp, 20', fixed to one wall. The upper shutter, 6, in the same way is engaged on one side by a staple and on the other by a hasp, 21', fixed to the other, 6<sup>2</sup>.

The said staples, 20 and 21, are retained respectively by the arms, 1<sup>1</sup>, 1<sup>2</sup>, of a three-armed lever, one arm, 1<sup>1</sup>, of which is fixed to one of the arms, 1<sup>2</sup>, of the spring, 11, which commands simultaneously the throwing out of gear of the shutters and that of the rod, 12, which carries the percussion hammers.

The hasps, 20' and 21', are retained by the curved branches, 1<sup>2</sup>, 1<sup>2</sup>, of another three-armed lever, *m m m'*. The arm, *m*, pivots at both of its ends around the two trunnions, *t t'*, fixed to the lateral wall of the drum, 1. On the lever, *u*, fixed to the arm, *m*, there rests the transmission shaft, 22, on which the arm, 1<sup>1</sup>, of the governing spring acts, and a recoil spring, *u'*, rests against the said lever, *u*.

The rod, 12, on which the hammers are supported is thrown out of

gear by means of an arm, 12<sup>1</sup> (fig. 3), the end of which carries a snug, which engages against the arm, 21, fixed to the coiled spring, 2.

The action of the apparatus is as follows:—

The apparatus being in normal or out of gear position, the shutters, 6 and 5, are thrown into gear successively by placing them, by means of the knobs, 24 and 25, in a suitable position. By means of the arm, 23, the rod, 12, is made to revolve; the spring, 11, is thus stretched and the shaft being thrown into gear cocks the hammers. The shutters and shaft carrying the hammers being thrown into gear, and the apparatus placed at the desired inclination, the pneumatic ball, 26, is pressed; the current of air actuates the governing spring, which is forced in the

posterior direction of the apparatus, arrow, *f* (fig. 1), and pushes the arm, 21, in the same direction, and also the levers, *v*, *l*<sup>1</sup>, and the shaft, 22.

The shutters and percussion hammers are thus thrown simultaneously out of gear. The shutters then bear against the leather guards, *b*, which deaden the shock.

Thus it will be seen that the more essential features of the invention are the three-armed springs, *r*, *b*, *r*<sup>1</sup>, the central arm of which is actuated by a current of air and carries an arm, 21, to throw the shaft carrying the percussion hammers out of gear; the arm, *u*, of this spring actuates a lever, *l*, *v*, *l*<sup>1</sup>, to disengage the shutters at one of their ends, and the arm, *r*<sup>1</sup>, is connected with a shaft, 22, bearing on the arm, *u*, of the lever with three arms, *m*, *x*, *m*<sup>1</sup>, which revolves so as to throw the shutters out of gear at their opposite end.

#### NOTES FROM THE WEST OF SCOTLAND.

THE visit of Mr. Harold Baker to Glasgow was looked forward to with much interest by several of Glasgow's local professionals, especially those more particularly engaged in the portraiture branch of photography.

Mr. Baker was brought to Glasgow under the auspices of the Glasgow Photographic Society (the parent of all the newer associations that have been formed during the last fifteen years). As the increase of amateur photography in the west of Scotland set in, it is noticeable that a distinct decline ensued in the popularity of the old parent Society, an association which has always been more or less under the governing hand of local professionals. Quite recently, the attendance at their regular monthly meetings may be said to have reached the vanishing point.

It was, no doubt, in the hope of giving a fillip to the existing state of affairs that the Council of the Glasgow Photographic Society sent an invitation to Mr. Baker to come north, for a pretty wide circle of invitations were sent out for the occasion, so that a warm and well-attended meeting might welcome that gentleman on Thursday night last. The large hall of the Philosophical Society was specially engaged also for the occasion, as showing the expectancy of those who had made the arrangements for the event, but unfortunately "The best-laid schemes o' mice and men gang aft a-gley," for, notwithstanding all the attempts that were made, only a mere handful turned up to welcome the popular portraitist, probably not more than twenty putting in an appearance. Those, however, that did attend had no reason to regret it, for Mr. Baker gave a most interesting lecture on several points connected with portraiture that were greatly appreciated by the professionals that it was specially applicable to.

It seems strange that there should not have been a better response on the part of both amateurs and professionals in and around Glasgow to an event of this description. Had any of our local popular lecturers been

billed to give a mere limelight lecture, it is a certainty the large hall would have been full to overflowing, and evidently technical lectures at the moment at least, so far as the west of Scotland is concerned, are not appreciated by professionals. On the other hand, with our amateur societies overflowing houses are the order of the day when any of our prominent local professionals give their demonstrations, to wit, the last meeting of the Glasgow and West of Scotland Amateur Association. Do professionals think they are above being taught, or has that common course of cliquism entered into photographic circles in Glasgow?

Already those interested in the forthcoming International Exhibition in Glasgow are beginning to discuss the matter of any monopoly being accorded for the right of photography inside the Exhibition. It is felt that, should any sole rights be given to any one firm in the matter, a great injustice would be done to the thousands upon thousands of tourists who will visit Glasgow during the run of this great function. On the last occasion monopolies were granted; but since then the hand camera has been instituted, and if every lady or gentleman who possesses a hand camera, and is desirous of using the same during their visit to the show, should be debarred in this respect, then a great injustice would be done to photographers generally throughout the entire world. It is hoped that the Council of the Exhibition will see that no such monopoly be given to any one, but some arrangement be come to—such as, for the payment of a mere nominal fee, any one can acquire permission to photograph on any one day within the precincts of the Exhibition. It is to be regretted that already a very strong expression of feeling has been made against the constitution of the Photographic Section of the Fine Arts Committee connected with this Exhibition, there not being a single

member of importance connected with the Glasgow and West of Scotland Amateur Association upon the same, and gentlemen who did so much for the welfare of photography and the Exhibition on the last occasion have been distinctly slighted and passed over for the coming fixture. The outcome of this will undoubtedly be the holding aloof from the undertaking by a number of those who have done so much in the past, and are capable of still doing so much in the future, to make or mar an event of such importance.

#### SCHUCKERT'S CIRCULAR SHUTTER FOR OPTICAL REFLECTORS, PROJECTING LANTERNS, AND ANALOGOUS APPLIANCES.

THE special applications of reflectors, electrical projecting lanterns, and analogous appliances render it desirable to provide devices for rapidly and completely obscuring or intercepting the conical bundle of rays emanating from the same, so that they may be set out of action without extinguishing the source of light or breaking the electric current which produces it. The devices hitherto employed for this purpose suffer from the defect that they allow light to pass through, or that they are injured by the heat rays concentrated upon them.

The present invention has for its object to provide an obscuring or intercepting device for circular openings, especially those of reflectors, which device has some resemblance to the well-known iris shutters of photographic cameras, and which, besides fulfilling the requirements mentioned above, can be handled with ease, rapidity, and certainty, and is therefore suitable as a signalling device.

Figs. 1 to 3 are diagrams of the improved shutter in different stages of operation, and fig. 4 is an axial section of the same on a larger scale, so as to show the details of construction.

The shutter chiefly comprises an annular frame, *a*, of such a size that it can be mounted in the opening to be obscured; a set of sickle-shaped segments, *b*<sub>1</sub>, *b*<sub>2</sub>, *b*<sub>3</sub>, *b*<sub>4</sub>, *b*<sub>5</sub>, of sheet metal or other suitable material, arranged round the inner circumference of the said frame, each segment being pivoted at one end on a stud, *c*, and connected at the other end by a short link or guide bar, *d*<sub>1</sub>, *d*<sub>2</sub> to *d*<sub>5</sub>, to a ring, *e*, adapted to turn on the axis of the frame; *a*, a ring, *e*, as mentioned above, mounted on balls, *f*, and provided with a handle, *g*, for turning it; a roller, *h*, fixed in the centre of the ring, *e*, and coaxial with the same, said ring being provided with a deep circumferential groove, *k*, and secured in its position by three suspension wires, *i*, placed at 120° to each other, or by other suitable means.

The width of the groove, *k*, increases from the centre towards the circumference of the roller, as shown in fig. 4.

When the shutter is fully open, as represented by fig. 1, the segments, *b*<sub>1</sub> to *b*<sub>5</sub>, partly overlap each other, and form a ring composed of several layers, because the entire circumference of the frame, *a*, is

provided with such segments. If the ring, *c*, connected with the segments,  $d_1$  to  $d_5$ , by the links, *d*, is turned in the direction of the arrow, the various segments are forced to approach the axis of the frame, *a* (fig. 2). During this time the circular opening formed by the segments is gradually getting smaller, until the segments slide into the groove, *k*, formed by the roller, *h*, and abut against the axle or core of the same, while they are firmly pressed against each other (fig. 3). As the various segments overlap each other, without forming any clearance, this opening of the frame, *a*, is completely obscured. In the case of electrical

reflector lamps, the roller, *h*, in the axis of the reflector, has little or no effect on the optical effect, because the central part is already inoperative, owing to the shadow of the negative carbon falling upon the same.

In cases, however, where the loss of light in the axis of the shutter must be avoided, the stationary roller, *h*, may be replaced by a movable roller fixed to the centre of one of the segments, *b*. For opening or closing the shutter, the ring, *c*, need not be turned more than 90°, as shown by experience, but the same effect may be obtained by turning the ring, *c*, only 45°, if the frame, *a*, carrying the pivots of the segments, is adapted to turn also, and in a direction opposite to that of the ring, *c*.

#### EDINBURGH PHOTOGRAPHIC SOCIETY'S ANNUAL EXHIBITION.

On February 4, the Annual Exhibition of the above Society was opened in their rooms, 38, Castle-street, by the Lord Provost of the City of Edinburgh, when there was a large attendance. The Lord Provost expressed his pleased surprise at the high artistic quality of the work shown, and highly commended the members for arranging such an Exhibition. An attractive musical programme, arranged by Mr. J. C. Lennie, was submitted and received with approval.

The Exhibition, which will remain open until February 25, contains 310 exhibits, a slight increase on last year; but the quality also shows a decided advance, and we think the Society may congratulate itself on having surpassed themselves this year. It might also be mentioned, *en passant*, that the membership of the Society is steadily on the increase, seventy members having been elected since October 1. Three gold medals have been offered this year against one last year, and in spite of the large increase in the number of non-members competing in the open classes, these gold medals (one was confined to members) have been carried off by members. The Judges were Messrs. Alexander Roche, A.R.S.A., Craig Annan, F.R.P.S., and W. M. Warneke, F.R.P.S., and while it would not be correct to say their verdict had given universal satisfaction—that is impossible—still, on the whole, the grumbling is only slight.

The Landscape, Seascape, and Architecture (open to all) classes contains fifty-eight exhibits. Here James Patrick, Edinburgh, an ex-President of the Society, gains the gold medal, with a beautiful view of Swanson, famous in the annals of Robert Louis Stevenson, whose haunts, as we mentioned in *Before the Convention*, Mr. Patrick had so fully illustrated.

The photograph, like its title—*A stilly hame! home, that viss with an earthly paradise*—is poetic in treatment, and perfect in technique; perhaps fault might be found with the mount and frame, but it is a thoroughly good photograph, and Mr. Patrick well deserves his win. The silver medal goes to Ernest G. Boon, Allassis, for *On the Lagoons*, a pretty example of Mr. Boon's well-known Venetian work; mounted on rough white paper, it almost looks like an old and well-preserved engraving. *Evening on the Chase*, which takes third place, would at once be recognised as one of W. Smedley Aston's work, quiet and restful in tone; it is a picture that

can be returned to again and again. In this class also might be mentioned, although no certificates have been awarded, *Ceiling at Thulestone Castle, Lander, A.D. 1675*, by Viscount Maitland. This is an almost perfect example of photographic technique. A very large example of F. H. Worsley Benison's work, with a poetic title, is in No. 2, but the enlargement is evidently too much, for the flying foam more resembles wool than water. *A rift in the Clouds* comes all the way from Kirkwall, but the lighting on the waves is hard, and the rays of light in the sky have too much of a faked appearance. In *South Door, Fountains Abbey*, John Stuart, Glasgow, has a good example of his well-known architectural work. In *Winter*, John Moffat, Edinburgh, shows a snow-laden view of St. Cuthbert's Parish Kirk and the Castle that should be popular with Edinburgh folks. *An Autumn Pastoral*, by Robert Ayton, is a good idea, and the composition is good, but it might and probably will be still further improved.

In Class II. (Portraiture, Figure, and Animal Studies, open to all) there are sixty-four entries. The gold medal is awarded to John Warrack, junr., for *Pietro*. This is a photograph that not a few members think wants its position explained. Plenty of condemnatory remarks will be made; we heard several. Let us try to find a good point or two. The photograph is distinctly impressionistic, and is not meant for microscopic inspection; but, viewed from the proper distance, it will be noted the pose is striking and not unnatural; there is a roundness and fleshiness about the arms and face and a depth about the picture that are destroyed by an unintended

close inspection. The Judges have probably judged it by the evident intention of the photographer, and added a point or two for its originality. Mr. Wm. Crooke, Edinburgh, takes the silver medal with his well-known portrait of *The late Sheriff J. Comrie Thomson, Q.C.* This picture is well known in London, and has in the figure a restful dignity befitting his office. The bronze medal goes to Mr. Robert Ayton, Edinburgh, for *Mistletoe Reflections*, representing a sweet little lassie "in maiden meditation, fancy free," moralising over some mistletoe; the pose is natural, and the result charming. *The Smithy*, by Mr. J. B. Johnston, gains a certificate; the light is finely managed, and the whole picture hangs well together. James Patrick shows a good thing here in *Light at Eventide*, an old lady reading at the cottage window. *A Pair of Elves* and *A Dangerous Pastime* are two photographs of nude children that will attract few admirers. In this class some splendid work is shown, but it is impossible in the space at our command to deal with it all. A few names might be mentioned, however: Messrs. John Moffat, John Stuart, Chas. M. Waue, R. S. Webster, Ernest G. Boon, Chas. Sweet, John C. Warburg, John Gunston, W. Smedley Aston, Wm. Norrie, W. Fisher Ward, &c.

In the confined-to-members the prize (gold medal) for the best photograph by an amateur member was gained by Mr. Alex. Allen with *Mary*. This is a portrait of the same old lady as he took premier honours with last year under the title of *Martha*, and the scheme of lighting is much the same, strong light on the profile of the face and the rest of the picture more suggestive than illustrative. It is an example of what is popularly known as Rembrandt lighting, and might be called a "strong" picture.

In Class III. Miss G. M. Gray takes first place with *A Shady Dell*, a fine woodland composition, slightly spoiled by two modern figures.

In Class IV. a strong portrait of *Rev. Dr. Whyte, Free St. George's*, by Mr. John Warrack, junr., takes the silver medal. The characteristic features of the reverend Doctor are powerfully portrayed.

Class V., Hand-camera Work, sees Mr. W. J. Croall in first place with two of his well-known sporting studies and a photograph of *White Bantams*.

Class VI., Landscape, &c. (open to amateur members), has about fifty entries, first place being taken by a small print of *The Last Load*, by Mr. Alex. Allan, the action of the figures being probably the strong point.

Class VII., Figure Studies, &c. (amateur members).—Here, as already mentioned, *Mary*, by Mr. Alex. Allen, takes pride of place. *Toilers of the Shore*, by Mr. Jas. Burns, takes the bronze medal, and carries out

title well. Miss Christian H. Curle has a beautiful picture of *Brier Roses* in this class.

#### LIST OF AWARDS.

Class I. (open to all), Landscape, Seascape, and Architecture.—Gold medal, Mr. James Patrick, Edinburgh; silver medal, *On the Lagoons*, Mr. Ernest G. Boon, Allasio; bronze medal, *Evening on the Chase*, Mr. W. Smedley Aston, Birmingham.

Class II. (open to all), Portraiture, Figure, and Animal Studies.—Gold medal, *Pietro*, Mr. John Warrack, junr.; silver medal, *The late Sheriff J. Comrie Thomson*, Mr. W. Orceke, Edinburgh; bronze medal, *Mistletoe Reflections*, Mr. Robert Ayton, Edinburg; certificate, *The Smithy*, Mr. J. B. Johnston, Edinburgh.

Class III. (open to members), Landscape, Seascape, and Architecture.—Silver medal, *A Shady Dell*, Miss E. M. Grey; bronze medal, *A Wreck*, Mr. Alex. Allan; certificate, *By the Sand Dunes*, Mr. W. J. Croall; *In the Woods—Summer*, Mr. John Warrack, junr.

Class IV. (open to members), Figure or Genre, including Animals and Still Life.—Silver medal, *Riv. Dr. Whyte, Free St. George's*, Mr. John Warrack, junr.; bronze medal, *A Symposium*, Mr. W. E. Drummond Young, certificates, *A Village Worthy*, Miss E. M. Grey; *The Miller's Man*, Mr. Alex. Allan.

Class V. (open to members), Set of pictures, not exceeding three, being work done by camera held in the hand.—Silver medal, *Getting near the Birds, White Bantams, A Close Point*, Mr. W. J. Croall; bronze medal, Mr. J. Yate Thomson; certificates, Mr. J. C. McKechnie; Mr. Alex. Allan.

Class VI. (open to amateur members only), Landscape, Seascape, and Architecture, up to and including half-plate.—Silver medal, *The Last Load*, Mr. Alex. Allan; bronze medal, *Requiescat in Pace*, Mr. James Burns; certificates, Mr. J. Yate Thomson and Mr. James Hay.

Class VII. (open to amateur members only), Figure or Genre, including Animal Studies and Still Life, up to and including half-plate.—Silver medal, *Mary*, Mr. Alex. Allan; bronze medal, *Toilers of the Shore*, Mr. James Burns; certificates, Mr. John Warrack, junr., and Mrs. Norman D. Macdonald.

President's gold medal for best picture in the Exhibition, the work of an amateur member:—*Mary*, Mr. Alex. Allan.

#### SOUTHSEA AMATEUR PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THE Eleventh Annual Exhibition of the above Society was held at the Society's rooms, 5 Pembroke-road, Portsmouth, on January 30 and 31. The Society is fortunate in having a splendid suite of rooms, very large and commodious and well lit, and therefore can have its annual Exhibition on its own premises. This year, however, the holding capacity of the rooms, large as they are, was taxed to the utmost, the Exhibition being quite the finest both in point of numbers of pictures hung (about 600), and the excellence of the work shown. The rooms were thronged throughout the two days with crowds of people, and the opinion of every one has been that it is decidedly the best show of its kind ever held in the district, and will probably do much to foster the photographic art in Portsmouth, even if its influence will not be more widespread. Of course, the introduction of Open Classes has had a lot to do with the success of this year's Exhibition, and some exceedingly fine work was submitted, and the Judges, Messrs. H. Snowden Ward, H. Symonds, and Dr. F. Lord had their work cut out in making their selection.

The following is the list of awards:—

#### MEMBERS' CLASSES.

Class A (Landscape).—1. *A Fallen Brother*, Mr. H. T. Lilley, M.A. 2. *A Country Road*, Mr. Gilbert Wood. 3. *Yealmtown, Devon*, Mr. H. J. Hissett.

Class B (Seascape).—1. *Barfleur Harbour*, Mr. F. J. Mortimer. 2. *Penlee Point, Cornwall*, Mr. H. J. Hissett. 3. *View from Piazza, Venice*, Mr. A. Fisher, A.S.A.

Class C (Figure).—1. *The Morning Paper*, Mr. H. T. Lilley, M.A. 2. *At Selsea*, Mr. F. J. Mortimer. 3. *Myself*, Colonel E. J. de Salis.

Class D (Architecture).—1. *Bonchurch*, Mr. Gilbert Wood. 2. *Part of Forum, Rome*, Mr. A. Fisher, A.S.A. 3. *At Wymering*, Major-General W. Byam, C.B.

Class E (Local Views).—Bronze medal, Mr. F. J. Mortimer.

Class F (Enlargements).—1. *A Hampshire Farmer*, Mr. F. J. Mortimer. 2. *Regatta at Helford*, Mr. F. A. Hedge.

Class G (Lantern Slides).—1. Set of six, Mr. A. Fisher, A.S.A. 2. Set of six, Mr. F. J. Mortimer. 3. Mr. E. H. Purvis and Colonel E. J. de Salis.

#### OPEN CLASSES.

Class H (Landscape).—1. *At Littleington, Sussex*, Viscount Maitland. 2. *The Waning of the Day*, Mr. G. Walford. 3. *Launching the Lifeboat*, Mr. Graystone Bird.

Class I (Figure).—1. *Head Study*, Mr. Pirie Macdonald, U.S.A. 2. Viscount Maitland. 3. *Meadow Maiden*, Messrs. G. Chaffin & Sons.

Class J (Hand-camera Work).—1. Set of six pictures from Venice, Dr. E. Boon (Italy). 2. Set of six Hand-camera Studies, Mr. W. Fisher-Ward. 3. Set of six Hand-camera Studies, Mr. Walter D. Welford.

Class K (Lantern Slides).—1. Set of six slides of Lightning, Mr. W. Archibald, U.S.A. 2. Set of six slides of Flowers, Mr. W. E. Cowan. 3. Set of six slides of Yachts, Mr. A. Watson. Extra bronze medal for set of six slides of Agricultural Subjects, Mr. E. R. Bull.

The awards in each case are: 1, Silver medal; 2, bronze medal; 3, certificate.

#### THE BENEVOLENT COMMITTEE.

THE Committee appointed by the Photographic Club, under the instructions of the Registrar of Friendly Societies to deal with the funds of the Photographic Benevolent Association, which has now been wound up, held its first meeting on January 31.

Mr. H. Vivian Hyde, of 33 Ritherdon-road, Upper Tooting, S.W., consented to act as Honorary Secretary, Messrs. J. Spiller and T. Fall as Trustees, and Mr. A. Mackie as Treasurer.

After settling several matters with regard to the procedure to be followed, an application for assistance was considered from a lady photographer who had several relatives dependent upon her, and whose case had been previously before the Committee of the P.B.A. It was agreed that a sum not exceeding 80l. should be devoted to releasing her from her difficulties.

The Committee next considered the case of an orphan, aged 4½ years, whose father was a photographer who had held situations in several first class firms. It was desired to place the child in a Home where she would be educated at a cost of 10l. per annum for 10 years, and a gentleman who had interested himself in the case had promised to contribute half the necessary amount provided the Committee would find the other half. It was decided to do this, and the Hon. Secretary was instructed to inquire upon what terms an annuity could be obtained from an assurance office.

An application from a photographer in the Midlands was referred back for further information and references.

## Our Editorial Table.

#### DEKKO PAPER.

Manufactured by Kodak, Limited, 43, Clerkenwell-road.

MESSRS. KODAK, LIMITED, are introducing a new photographic printing paper to be known as Dekko paper, the special feature of which is that it can be exposed, developed, and fixed in an ordinary room illuminated by artificial light or weak daylight. It is made in four varieties: Glossy, which has a surface similar to Solio P.O.P., and gives fine detail; matt, which has a fine-grain, velvety matt, mauve-tinted surface; egg-shell matt, which is a fairly heavy white paper, with a matt surface, showing a pleasing irregular grain; matt antique, which is an antique cream-tinted paper with a surface like hand-made paper. Richness of colour and breadth of effect are noticeable qualities given by this paper. Any developer can be used with the paper, and Eastman's special developer cartridges are well suited for use with it. A great variety of results may be obtained on Dekko by alterations in the time of exposure and development. Long exposure and development with dilute developers tend to give warm blacks, while short exposure and longer development with stronger developers produce blue-black tones. A range of tones varying from red chalk, through sepia and brown, to purple black, may be obtained by printing in daylight until the deepest shadows are faintly visible, and then developing with the "warm-tone" developer. This method will yield a red-brown colour. For brighter reds a longer exposure should be given, and purples are obtained by shorter exposures.

The following are the principal directions for use:—

Dekko paper may be safely handled for the purpose of placing in the printing frame and developing at a distance of eight or ten feet from ordinary full-flame artificial light, or three or four feet away if the light is turned low. With the Welsbach gaslight or daylight it is necessary to reduce the light somewhat by shading the lamp or window with one thickness of thin orange paper; if there is a yellow shade or dark shade on the window, the orange paper need not be used.

To expose, place the paper in contact with the negative in the printing frame. Make the exposure while holding the printing frame at a distance of about six inches from an artificial light, or two feet from a window, covered with one thickness of tissue paper. Length of exposure varies with the density of the negative and the strength of the light. With artificial light, using the same negative, the various rates may be approximately compared as follows: Welsbach incandescent gaslight, strongest; incandescent electric light, about one-half as strong as the Welsbach gaslight; ordinary gaslight, slightly weaker than the incandescent electric light; oil lamp of ordinary size, about one-third the strength of an ordinary gas burner. With a negative of medium density,

expose three to five minutes at a distance of from six to eight inches from an ordinary gas burner.

*Metol-hydroquinone Developer.*

Metol .....	8 grains.
Hydroquinone .....	30 "
Sulphite of soda (cryst.) .....	$\frac{3}{4}$ ounce.
Carbonate of soda (cryst.) .....	$\frac{3}{4}$ "
Water .....	10 ounces.

Dissolve and add to each ounce of developer about 2 drops of a solution composed of—

Bromide of potassium .....	$\frac{1}{2}$ ounce.
Water .....	5 ounces.

This developing solution is to be used without dilution.

To obtain a series of tones varying from red chalk, through sepia and browns, to a purple black make up the following developer :—

No. 1.

Citric acid .....	2 $\frac{1}{2}$ ounces.
Ammonium carbonate .....	1 ounce.
Water .....	10 ounces.

No. 2.

Sulphate of iron .....	2 $\frac{1}{2}$ ounces.
Water .....	10 "
Sulphuric acid .....	10 drops.

For use mix three parts of No. 1 with one part of No. 2.

Expose the print for three or four seconds to daylight until the image is just visible in the deepest shadows. This will, upon development, give a red-brown colour. For brighter reds give a longer exposure, while for purples expose for a shorter period.

First immerse the prints for a few moments in water, then pour off the water and flow over either of the above developers. The image will appear almost immediately, and, when it is sufficiently developed, rinse quickly and immerse in the following fixing bath :—

*Fixing Bath.*

Hyposulphite of soda .....	4 ounces.
Alum (crystals) .....	1 ounce.
Water .....	16 ounces.

Fix for fifteen minutes, keeping the prints separated. When fixed, transfer to the washing tray.

THE CADETT P.O.P.

Manufactured by Cadett & Neall, Ashted, Surrey.

In addition to the "soft" brand of P.O.P., a sample of which we tried some weeks ago with the greatest success, Messrs. Cadett & Neall are issuing another variety termed the "brilliant" brand. The characteristics of this surface are that it allows of prints of very great brilliancy being obtained, and that therefore it is especially suitable for portrait negatives. A brief trial of the paper convinces us that it is admirably adapted for the special purpose for which it is prepared, and we have no doubt that it will be exceedingly popular with professional photographers. We congratulate Messrs. Cadett & Neall not only upon the excellent qualities of their printing-out papers, but also upon their shrewdness and foresight in catering for the tastes of the photographic public, among whom, if our opinion counts for anything in the matter, gelatino-chloride is destined to have quite as long a run as albumen.

GRAVURA.

Manufactured by the Paget Prize Plate Company, Watford.

THE Paget Company have sent for us trial samples of their new gaslight development paper, which we hope to fully report on next week. A series of specimen prints made on the paper lies before us; these have a wide range of colour—red, sepia, brown, purple-black, black—a feature which should render the paper exceedingly popular, the colours being obtainable by exposure and development alone, and not by toning.

CATALOGUES RECEIVED.

W. F. Slater, 169, Southampton-street, Camberwell, S.E.

MR. SLATER is shortly removing to more commodious premises, and sends us his eight-page list of second-hand apparatus, which he is desirous of clearing off. A glance through the list shows that many bargains are available. From the prices quoted a reduction of ten per cent. is allowed. The list should be in the possession of all those on the look-out for "cheap lines" of second-hand apparatus and sundries.

Sands, Hunter, & Co., 20, Cranbourne-street, Leicester-square, W.C.

In their latest second-hand list, which Messrs. Sands, Hunter, & Co. have sent us, a wide variety of hand cameras finds detailed reference, nine pages being devoted to those instruments. Tourist and studio cameras follow, and of lenses, portrait, euryscope, rectilinear, wide-angle, landscape, casket, triplets, and stereoscopic form an assortment probably not to be found in any other catalogue of this nature. Complete sets, lanterns, changing boxes, shutters, and miscellaneous make up the remainder of the catalogue, which extends to thirty-two pages, and should tempt all those who love a bargain in second-hand photographic apparatus to procure a copy. As a source of such purchases, as well as for the hire of apparatus, Messrs. Sands, Hunter, & Co. have long enjoyed a well-deserved reputation of the highest kind.

Ross, Limited, 111, New Bond-street, W.

Two supplementary lists have recently been issued by Messrs. Ross; these treat of the Company's latest novelties in photographic and lantern apparatus, lenses, microscopes, &c. We note that prominent mention is given to a new lens, called the Ross Symmetric Anastigmat, the principal characteristics of which are thus outlined :—

This new Extra-rapid Series is introduced to provide an improved lens replacing the Universal Symmetrical Series, with only a very small increase in cost of the larger sizes. Like the Universals, these new lenses work with an intensity of  $f-5.6$ , but with superior marginal definition. They are spherically and anastigmatically well corrected over the whole field, and, wider angles being embraced when smaller apertures are employed, they may be considered universal in their adaptability. They are extremely suitable for studio work and for portraits and groups out of doors. When adapted to cameras provided with focal plane or other very rapid shutters, these lenses will also be found invaluable for animal studies, racing pictures, street scenes, and other work requiring instantaneous exposures.

The three smaller sizes will be found adapted for hand-camera work. When stopped down to slightly smaller apertures, they are suitable for all kinds of general photography, including copying and enlarging.

The Birmingham Oxygen Company, Limited, Saltley Works, Birmingham.

THIS Company not only supplies compressed oxygen for medicinal and other purposes, but also pure hydrogen, coal gas, nitrous oxide, carbonic acid, and compressed air, the uses of which are many. Apparatus for the production of liquid air is also listed. With photographers and others interested in optical projection Brin's oxygen has long borne the highest reputation. This list should be obtained by all who employ compressed gases. The Company point out that, next to its value as a medicine, the most important applications of compressed Brin's oxygen are the result of its property of yielding with common coal gas the highest temperature produced by flame, enabling an intense and easily regulated "local" heat to be produced. The most popular of its uses is due to this property, and is the "limelight" chiefly used for optical lanterns and stage effects. Other important uses are the oxygen blowpipe (for melting platinum, for very fine brazing in jewellers', cycle, and engineering work generally, and for lead-burning in chemical and gas works), and also the oxygen injector furnace for rapidly melting small quantities of the most refractory ores—gold, silver, and other precious metals. Prices of cylinder fittings, and many useful, practical hints are included in the list.

\* \* Owing to the heavy demands on our space this week we are compelled to hold over a portion of Editorial Table.

## News and Notes.

THE YORKSHIRE EXHIBITION.—The total attendance at this Exhibition, which closed on the 31st ult., was 125,903. Sixty seven photographs, value 100*l.* 4*s.*, were sold.

THE Brentford Photographic Society proposes holding an Exhibition on March 15 and 16. It has been decided to have an open class, and Mr. John A. Hodges has kindly consented to act as Judge.

PHOTOGRAPHIC CLUB.—Wednesday evening, February 15, at eight o'clock. Beginners' Night. "Toning and Modifying Prints after Development," by W. Ethelbert Henry, C.E. Visitors will be welcome to these demonstrations.

MR. HOOLE'S lecture on "Lantern-slide Making," which we published in our SUPPLEMENT last week, was read before the Croydon Microscopical and Natural History Club, and not before the Sutton Photographic Club, as stated.

MESSRS. ELLIOT & FRY have just been awarded the gold medal for their charming exhibit of photographic enlargements at the recent Grosvenor Exhibition, which included portraits of the Queen, Sir Alfred Milner, Mr. Rhodes, and several typical English beauties.

**THE Thornton Heath Polytechnic Photographic Society** has recently been formed. The principal officers are:—*President*: Dr. Fowler.—*Committee*: Messrs. B. E. Edwards, Ironmonger, Bynoe, Chatwood, Watson, Duff-Smith, W. H. Rogers, Robertson, G. S. Addison and Swale.—*Hon. Treasurer*: Mr. Gardner.—*Hon. Secretary*: Mr. V. Smith.

**THE Fourth Annual Smoking Concert** of the *employees* of Mr. Jonathan Fallowfield will be held at the London Tavern, Fenchurch-street, E.C., on Friday, February 17, at 7.30 p.m. Mr. F. W. Hindly will preside. An interesting and attractive programme of nearly thirty items has been arranged, and, as on former occasions, an enjoyable evening should result.

**THE West London Photographic Society's Tenth Annual Exhibition of Members' Work** will be held on Friday and Saturday, February 17 and 18, 1899, at the Broadway Lecture Hall, Hammersmith, W. It will be open to members and their friends by invitation card on Friday, February 17, 7 p.m. to 10 p.m., and to the public free on Saturday, February 18, 4 p.m., to 9 p.m. There will be an exhibition of lantern slides each evening.

## Patent News.

THE following applications for Patents were made between January 23 and January 28, 1899:—

**COLLOTYPE PRINTING MACHINES.**—No. 1494. "Improvements in Collotype and similar Printing Machines." A. COE.

**DARK SLIDES.**—No. 1527. "Improvements in Photographic Dark Slides." G. R. NICHOLLS.

**MECHANICAL SLIDE.**—No. 1617. "A New or Improved Mechanical Slide." E. APPELBY and A. C. THOMAS.

**LENSES.**—No. 1699. "Improvements in certain Photographic Lenses." Complete Specification. H. D. TAYLOR.

**OPTICAL PROJECTION.**—No. 1802. "Improvements in the Means of Viewing the Enlarged Pictures obtained by Optical Projection." J. E. THORNTON and C. F. S. ROTHWELL.

**PROJECTING ANIMATED PHOTOGRAPHS.**—No. 1815. "Improvements in Apparatus for Projecting Animated Photographs on to a Screen." E. T. SAUNDERS.

**HAND CAMERA.**—No. 1818. "The Landore New or Improved Hand Camera." Complete Specification. E. ALAND.

**STEREOSCOPIC PHOTOGRAPHY.**—No. 1964. "Improvements in relation to Stereoscopic Photography." J. E. THORNTON.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

February.	Name of Society.	Subject.
11.....	Oroydon Camera Club .....	Lantern Show.
13.....	Bradford Photo. Society .....	(Demonstration: Bromide Enlarging. A. Priestley.
13.....	Camera Club .....	Exhibition of Members' Lantern Slides.
13.....	Kingston-on-Thames .....	(Popular Artists of the Day. Kindly lent by Sir George Newnes & Co., Ltd.
13.....	Leigh .....	Prize Slides.
13.....	Oxford Camera Club .....	(Lecture: Practical Points in Exposure, Development, and Printing.
13.....	Richmond .....	Modern Methods of Book Illustration. Ernest Morgan.
14.....	Birmingham Photo. Society .....	Demonstration: Platinotype Printing. W. T. Greatbatch.
14.....	Hackney .....	Paper by E. J. Wall.
14.....	Leeds Photo. Society .....	Instantaneous Photography. H. B. Buckley.
14.....	Shropshire .....	Description of Apparatus for taking Photographs of Minute Objects with the Aid of the Microscope. F. E. Armytage.
15.....	Ashton-under-Lyne .....	Affiliated Societies' B Set of Slides. Reader, Thomas F. Kershaw.
15.....	Brentford .....	Spotting, Retouching, and Mounting. Mr. Abbott.
15.....	Oroydon Camera Club .....	Hand-camera Work. G. H. Gear.
15.....	Leeds Camera Club .....	The River Wharfe from Source to Mouth. F. Brundritt.
15.....	Photographic Club .....	Toning and Modifying Prints after Development. W. Ethelbert Henry, C.E.
15.....	Southsea .....	Some Practical Points in Photography. F. J. Mortimer.
15.....	Woodford .....	Colours in Lantern Slides. E. Marriage.
16.....	Bolton Mutual Photo. Society .....	Ramble through Land. Rev. J. J. F. Halliway.
16.....	Camera Club .....	Experiences at the Court of the Ameer. A. G. Gray, M.B.
16.....	Goldsmiths' Institute .....	The Camera and the Wheel. F. O. Bynoe.
16.....	Leigh .....	Competition: Picture, Morley Hall.
16.....	Liverpool Amateur .....	Demonstration: Development. F. Anyon.
16.....	London and Provincial .....	Lantern Night.
16.....	Putney .....	Elementary Carbon Printing. T. Coyah.
17.....	Oroydon Microscopical .....	Lantern Slides. Mr. Sandell.
17, 18 .....	West London .....	Annual Exhibition.
18.....	South London .....	Exhibition Entries close.

**Hackney Photographic Society.**—January 31, Mr. W. L. Barker presiding.—The subject for the evening was a lecture by Mr. J. H. GEAR on

### PICTORIAL WORK.

In speaking of field work, he said that the photographer should keep his eyes open and be ready to photograph any pleasing composition he might see, and not go out merely with the idea of looking for some particular class of subject; in other words, he should not seek for a picture to fit a title, but should find his title to suit the picture. It was a good plan to include in the field kit a broad pencil and some paper, and, when a likely subject met the eye, the lines of it should be sketched on the paper. This was a surer method than the mere observation of the focussing screen, for the inversion of the picture and the colour were deceiving. Having drawn a rough outline of the subject, it could easily be seen whether the composition were faulty or not; should it be faulty, it could easily be seen in what respect it was bad, and a remedy might be suggested in the alteration of the position of the camera or the use of a lens of a different focus. With regard to the question of focussing sharply or otherwise for pictorial work, the lecturer preferred to get all parts of his negative sharp, and to get whatever diffusion of focus he might want by interposing one or more sheets of celluloid between the negative and the print. In the course of the lecture he dealt fully with the subject of the after-treatment of the negative, and showed by means of samples how much of this was often necessary to get good results. He advised all would-be pictorial photographers to obtain a good stock of cloud negatives, for, even if the clouds were obtained on the same plate as the landscape, it would rarely be suitable from a pictorial point of view. Mr. Gear ended a very able lecture with an explanation of combination printing.

**Lewisham Camera Club.**—January 24.—A demonstration was given by the Hon. Secretary (Mr. Eastwood) on the

### REDUCTION AND INTENSIFICATION OF NEGATIVES.

He described the class of negatives which would be benefited by reduction, as those which having had a sufficient exposure had been over-developed, also those which, having been over-exposed, had been over-developed in the hope of obtaining density, but where the result had been fog these latter requiring clearing, and afterwards intensification. He showed how apparently hopelessly spoiled negatives in which the image was almost invisible could be restored to usefulness, and also brought specimens of weak, flat negatives, half of each having been previously bleached with mercury, and which he then intensified before the meeting, and passed round to show the improvement produced on the half-treated. Reference was made to the introduction of the new salt, persulphate of ammonia, by Messrs. Fuerst, Brothers, and to its unique property of attacking and reducing the densest portions of a negative in preference to the weaker details, and he experimented upon several hard chalky negatives, showing its value in this respect.

**North Middlesex Photographic Society.**—January 30, Mr. H. Walker in the chair.—Mr. H. Stuart (Hon. Secretary) gave a demonstration on

### LANTERN MANIPULATION.

He said that this was a novel subject with which to fill up an evening, but he thought it would prove interesting, and, what was more to the point, instructive. In a Society amongst whose members may be found a dozen or so who were quite capable of giving a demonstration or lecture on any subject connected with photography, there were only one or two who were capable of manipulating the lantern on the many evenings when it was in requisition, and it was thought that this state of things should cease. The lecturer first showed how to use the gauge for telling the quantity of gas in the cylinder, and then connected up a blow-through jet direct with the cylinder without a regulator, and showed how the best light could be got. Next the regulator was used, the advantage of which was apparent in the control obtained over the supply of gas. The mixed jet was then shown, the increase in the light obtained being very marked. There was absolutely no danger in connexion with its use, the worst that could happen being a smart snap if the hydrogen tap was turned off first, and the rubber tubes might get blown off, the only possible danger being in the cylinder, in which the gas is under a pressure of 120 atmospheres when fully charged; but, as these are thoroughly tested before being filled, an accident is remote. The lantern was next fired up, and the mode of centering the light and getting an even disc was shown. At each stage members were invited to come up and try their hand at it, many availing themselves of the offer. The lecturer wound up by giving a few precautions that should be taken, and a few hints to facilitate working. The great thing in operating at the lantern was that everything should go smoothly and without hitch, otherwise it was very disconcerting to the lecturer, who was relying upon the operator.

**Newcastle-on-Tyne and Northern Counties Photographic Association.**—At the last meeting of this Association Mr. Baldwin, a well-known figure in the world of photographic commerce, gave a demonstration in the working of a new paper, entitled

### GRAVURA.

which the Paget Prize Plate Company are about to put upon the market. This paper, which is exposed and developed in the manner of the familiar slow bromide papers, places within the control of the operator three distinct tones of black, brown, and red. One and all were delighted with the successful results obtained by Mr. Baldwin, who confessed to working at some disadvantage, as his knowledge of the paper and the developer sent down by the firm was limited, yet secured the desired tones with ease, using as the lightning medium magnesium ribbon of various lengths at a fixed distance from the negative. The resultant pictures had much of the quality of carbon prints, being soft and delicate in tone and full of detail.

**Plymouth Photographic Society.**—January 27, Mr. J. Trouern Trend in the chair.—Mr. EDWARD G. TURNER gave a lecture,

A GLANCE AT THE CHEMISTRY OF SOME OF THE PHOTOGRAPHIC PROCESSES, which, with the aid of experiments, the members present were able to fully understand. Mr. Turney touched upon the chemistry of the various manipu-

lations in the making of a negative, from the preparation of the emulsion to the washing after fixation, and also with that of paper prints in different processes. He said that silver was the sheet anchor of the photographer, and probably the first silver that a beginner used was that of a shilling, with which he purchased his first dozen of quarter-plates, but it was hardly necessary for him to say that no chemistry was involved in that transaction. A very hearty vote of thanks was accorded the lecturer, and opinions were freely expressed as to the desirability of amateur workers acquiring a knowledge of the chemistry of photography, if only a slight one.

### FORTHCOMING EXHIBITIONS.

1899.

- February 10-25 ..... Edinburgh Photographic Society. Hon. Secretary, J. S. McCulloch, 2, George-street, Edinburgh.
- „ 13-18 ..... Photographic Society of Ireland. Hon. Secretary, 35, Dawson-street, Dublin.
- „ 16-23 ..... Northampton. E. J. Felse, 53, Adams-avenue, Northampton.
- „ 21-24 ..... Hastings and St. Leonards. Exhibition Secretary, A. Brooker, 21a, Wellington-place, Hastings.
- „ 23-25 ..... Woolwich Photographic Society. Hon. Secretary, F. W. Machen, 161, Griffin-road, Plumstead, S.E.
- „ 27-March 4 Birmingham. C. J. Fowler, Court Mount, Erdington, near Birmingham.
- March 4-11 ..... South London. Hon. Secretary, A. E. Allen, 27, Princes-square, Kennington Cross, S.E.
- „ 20-May 13 ... National Trades and Industrial Exhibition, Bingley Hall, Birmingham. Manager, Walter D. Wellford, 19, Southampton-buildings, Chancery-lane, W.C.

## Correspondence.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

### PHYSICAL DEVELOPMENT OF P.O.P.

To the EDITORS.

GENTLEMEN,—As a poor provincial, who has not the opportunity of attending the meetings of the Royal and of the London and Provincial, may I be allowed to say a word or two on the subject of the debate on Physical Development of P.O.P., which has recently been engaging the attention of those august bodies.

The account, in the columns of your JOURNAL, of my series of experiments has apparently not escaped notice, although I had begun to think it had been overlooked, or else not deemed worthy of attention. I am extremely pleased and gratified to see that Mr. Sterry has taken the matter in hand, and devoted attention to further experiment on the same lines as myself. There are possibilities in several, probably many, of the methods I used, and I was led to publish the whole of them in the hope that gentlemen with more time at disposal would investigate further in the manner Mr. Sterry has done.

On the other hand, Mr. Bullen's attitude towards my experiments strikes me as savouring rather of giving a verdict before hearing the evidence. Mr. Bullen, according to your report, had not followed out my instructions, because he knew it would be useless. This is scarcely a scientific manner of investigating a new method, to say the least of it. Also, at the London and Provincial he is reported to have described me as "premature" because I had tried to cut down exposures to too short a period. As a matter of fact, I did not try to cut exposure at all, but was compelled to do so when using potassium bichromate as an accelerator to avoid general fog.

Perhaps, if Mr. Bullen will try to realise that he and I were not aiming for the same goal, he may then be inclined to grant that my method is not worthy of quite such severe condemnation as he has meted out to it. Mr. Bullen's desire is for a method of development which gives colours suitable for subsequent gold toning. For that purpose I am quite content to use the formula published by the Eastman Company with their Solio paper; it answers admirably in my hands. But when good browns are wanted without resort to gold toning, and intended to give entirely different effects to gold toning, my method of developing with pyro and very dilute potassium bichromate has, I fancy much to recommend it.—I am, yours, &c.,

W. E. A. DRINKWATER.

2, Radford-place, Plymouth, February 3, 1899.

### LIGHT-FILTERS.

To the EDITORS.

GENTLEMEN,—Some time ago I had occasion to test some methods of light-filtering, and, in course of my experiments, found that a perfectly colourless acid and bright solution of disulphate of quinine would, with a full light upon it, cut off most of the actinic rays, dependent, of course, on the strength and depth of the solution, which suggested itself as an excellent medium for the dark-room window, a glass tank containing it taking the place of the ruby glass, by which we daily damage our eyesight. Of course the containing vessels might be of yellow glass, which would add additional security without interfering with the brightness of the illumination, which would be a desideratum in any case. In my experiment I used a white glass bottle, about an inch through, and a thirty-grain solution of quinine, but other matters prevented me following up the matter, which I think it might be well worth doing.—I am, yours, &c.,

E. DUNMORE.

## Answers to Correspondents.

\*.\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\*.\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*.\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

A. P. Reid, 81, High-street, Belfast.—Photograph of launch of "Oceanic."

F. Woodcock, sen., Douglas Head, Isle of Man.—Flashlight photograph of banquet to Mr. Hall Caine at the Villiers Hotel, Douglas, Isle of Man.

W. M. STUART.—Burrongs & Wellcome, Holborn Viaduct, E.C.

COLOURING.—Mr. T. Pilkington, whose address we believe, but are not sure, is Sackville-street, Piccadilly, W.

G. P. NORMAN.—The London Stereoscopic Company, 54, Cheapside, E.C., make a speciality of that kind of work, and would, doubtless, undertake it for you.

S. R.—Send us one or two of your failures, then we shall be better able to assist you than we can from your description; from that we can in no way account for the failures.

G. M. A.—1. For rubber stamps address Mr. E. M. Richford, 44, Snow-hill, E.C. 2. What kind of printers' blocks do you mean? Kindly state and we will give the desired information.

H. H. COBB.—1. Between Nos. 1, 3, and 4 on your list there is little or nothing to choose. All, save No. 2, may be used as single lenses. 2. We have not used it ourselves, but, from the principle adopted, we should say that it would evenly illuminate the negative. We think you could use it successfully.

CRAYONS FOR BLACK-AND-WHITE WORK.—C. B. says: "Will you tell me which is the best crayon for working up bromides in black-and-white, or if any kind will do?"—Ordinary crayons answer quite well, but they should be the same colour as the picture they are used upon, which is not always actually black.

GHOST IMAGE.—T. FIELD. The ghost, or double, image is due to a minute hole somewhere in the camera. From its position we suspect it will be found in the front, either by the flange of the lens or by the screws of the rising or cross fronts. It may, however, be somewhere in the foremost portion of the bellows. Careful examination against a strong light will reveal it.

CANARY MEDIUM.—S. A. M. asks what is canary medium and where it can be obtained, also whether it is a safe light. Canary medium is a yellow paper, and yields a very pleasant light to work by. We have obtained it from Mawson & Swan, Soho-square, and it is probably kept by most dealers. It is quite safe for ordinary plates, but is not safe for orthochromatic ones.

RESIDUES.—F. T. WRIGHT says: "Can you kindly tell me the best method of precipitating the silver in hypo bath after fixing, and should be glad if you can recommend a good book on residues?"—In reply: The silver may be precipitated as sulphide by the addition of solution of potassium sulphide, four ounces in about sixteen ounces of water. We know of no book on the subject.

BOOKS ON COLLOTYPE AND HALF-TONE.—X Y Z says: "Please favour me with name and address of what you judge to be the best text-book for colliotype and half-tone block-making? I have had no experience in either process, but am desirous of looking into them to see whether or not I should take them up as an addition to business."—In reply: *ColloTYPE*, by Schneiders, published by Bliffe & Son, 3, St. Bride-street, E.C.; *The Half-Tone Process*, by Verfassers, published by Percy Lund & Co., Bradford.

**CARBON TRANSFER PAPER.**—S. W. The reason that the gelatine solution with which you intended to coat the rough drawing paper "went clotty" is that you used too much chrome alum. This is proved by the fact, that when more heat was applied it did not regain its former fluidity. Probably with about half the quantity of the chrome alum all would have gone well.

**COMPOSITION FOR THE LUXOGRAPH.**—PERPLEXED says: "I worked a Luxograph some years ago and used to get well-exposed negatives with a very moderate exposure, about six seconds. I have recently had occasion to use the same apparatus again, but I cannot get the composition to answer, and have been greatly inconvenienced. Do you know the proper ingredients, and where I could purchase them?" Some reader may be able to supply the information asked for.

**COPPERAS.**—A. C. DENTYER. You have been trying the wrong material entirely. It is quite true that, in the wet-collodion days, some operators preferred the commercial copperas to the protosulphate of iron. But you have been trying with sulphate of copper, an entirely different thing. Copperas is sulphate of iron, and, when that name is used for it, the common commercial salt, the crystals of which are usually somewhat oxidised, is usually understood.

**FINISHING BROMIDE ENLARGEMENTS.**—MIRA says: "I cannot get crayons to take well on bromide enlargements, the surface seems to have little or no tooth. Can you tell me how to get a tooth?" With the ball of the forefinger, or, if the surface is large, with a piece of close felt, rub over with a little fine cuttle-fish powder, or fine pumice powder, so as to slightly abrade the parts to which the crayon is to be applied. Which-ever powder is used, it should be finely sifted to remove the coarse particles, so as to avoid scratches. An ink eraser will answer much the same end.

**CELLULOID VARNISH.**—COLLODION asks how celluloid varnish is prepared? He has dissolved celluloid in acetone, in which it dissolves perfectly; but, when pouring it on glass, it dries with a white matt surface, like ground glass.—We do not know how the commercial "celluloid varnish" is made, but we believe it contains no camphor, which is one of the ingredients of the usual celluloid. But celluloid, as met with commercially, is by no means a definite compound, as it varies considerably. In place of using acetone, try amyl-acetate with the sample you have; that may yield a clear film.

**CRACKED FILM.**—FIDO writes: "I have an old collodion negative, taken nearly thirty years ago, of my late father. The film is cracked all over with map-line marks, so that the prints from it look as if they were printed on a skeleton map, the lines, of course, showing black. Is there any known way of repairing the film?"—There is no way of actually repairing the film, but the cracks may be filled up so that they show scarcely, or not at all. Take some lamp black, in fine powder, and dust some over the negative, then, with the ball of the fore finger, rub it lightly over the negative. That will fill up the cracks. The superfluous black must then be dusted off.

**PLATINOTYPE PRINTING.**—W. WALTERS says: "So much has been said of late in your BRITISH JOURNAL OF PHOTOGRAPHY about platinotype that I have been prompted to send you two prints for your inspection. They were printed in the ordinary way—indiarubber pads at the back, Company's paper, cold-bath process, and I have used their paper until this occurred last year. I may say I started using their paper in either 1888 or 1889, so that I know something of the process, but never until last year did I have such a thing occur. Perhaps, through your paper, you may be able to throw some light on the subject."—In reply: The marks complained of are dark patches, which, we should imagine, were caused by silver stains or other deposits on the negative coming into contact with the sensitive iron salt. It is unreasonable to condemn a printing paper on such unsubstantial evidence as this.

**ADVICE WANTED.**—J. C. (South Wales) says: "I am anxious to get a situation in the photographic trade, and I should like if you will kindly let me know what you think of my work that I am sending you on P.O.P., Platinotype, and Velox. The photographs have all been taken and finished by myself. Can also print on Nikko and bromide paper, and make enlargements. I have not had any lessons from professional men, but have learned the business myself. If I want to know anything, I just look for it in your paper, and find what I want at once. I am young (seventeen years of age), and only an amateur. Should you think me worth 2s. or 3s. board and lodging per week? Once I get a start in the business with a good man, and as I take great delight in the work, I should soon learn."—The work sent shows promise, but it is not up to professional standard. Our correspondent would probably be worth the salary mentioned as an improver, which is the position we should recommend him to apply for.

**SOUTH-LIGHT STUDIOS.**—FOGGED LIGHT says: "Noticing your reply to a query from 'Rex' in the JOURNAL dated January 27, I really think you have made a mistake in advising the young man to undertake a studio built with south light. I don't think it worth the candle to a professional. An east or west light is quite bad enough to work, and only a professional can realize the fact. 'Rex' will, I am afraid, be much disappointed with a south-light studio."—We imagine this correspondent's experience in photography is very circumscribed, particularly as he says, "An east or west light is quite bad enough to work." How many professionals wish they had one or the other of them in place of what they have. Amongst the best portraits and studies we have some were taken in a studio with a south light. Good portraiture depends upon the skill of the photographer, not the aspect of the studio, though, as we told "Rex," a south aspect was somewhat more difficult than some others. We assume he is a photographer who understands his work.

**NEGATIVES AND THE CARRIERS ACT.**—MESSRS. WALFORD & CO., LIMITED, write: "Can you oblige us by any information as to the question of non-liability in the case of negatives or photographic plates with regard to the Carriers Act? We desire to know if there ever has been any test action upon this point. As we know you are always interested in matters appertaining to photographers, we think it just likely that you can inform us of any detail upon this point: We delivered to Messrs. Pickford certain cases. One never arrived, and it contained exposed plates (undeveloped). The carriers decline to make any compensation, on the ground that, by an Act bearing date of William IV., they are not liable for glass damaged or lost in transit. If there has been a test action, it will remain upon that decision."—We do not, for the moment, remember any test action on the point, but we have never heard that carriers are not liable for glass damaged or lost in transit if it is properly packed and addressed. We do know that carriers and railway companies make compensation in such cases when the fault is due to them. Perhaps some of our readers may tell us the law on the point.

**ENAMELLING OR BURNISHING.**—STUDIO. R. J. SCOTT says: "I should be pleased to have your opinion respecting the following: 1. Do you think there is an advantage gained by using an enameller in place of a bar burnisher for albumen prints, is there a better gloss obtained? 2. And I might here also ask your opinion respecting studio I am about to erect: Is the following about correct? Ridge roof glazed close up to ridge; length of studio inside, 30 feet; width of studio inside, 14 feet; height of studio to eaves, 8 feet 6 inches; slope of studio roof, 40 degrees; 6 feet of studio roof either end, opaque; 5 feet of studio side, either end, opaque; 2 feet 6 inches of studio from floor, opaque; all-round glass, 36 ounces, top thinner at side; matchboarding inside painted light green; curtains at side light green and white; curtains at top light green; a flat white curtain about the height of eaves. Any improvement on the above you can suggest I should feel obliged. Do you think lean-to roof preferable? I have given dimensions of studio, &c., again this week, as I thought, perhaps, I did not make it quite clear enough last week."—In reply, 1. There is not much to choose between them when both are at their best. 2. The studio, as described, will be an admirable one. The only suggestion we can make in the way of alteration is that the side be plain, instead of ground glass, unless there be an unpleasant outlook that it is desired to hide.

**STUDIO CONSTRUCTION.**—COPING writes: "I am venturing to ask your opinion on a point involved in the alteration of premises for our business. The owner of the property seems unwilling to have the heavy stone coping removed for the distance of the side light (12 feet 6 inches), and the builder intimates that it will mean a difference of not less than 2 feet between the side and the top light. Now, as the side wall is very low (only 3 feet 6 inches from floor to ceiling), should you consider that the blank space of 2 feet would prove any detriment in actual work? We are starting the side light 2 feet from the floor, with 2 feet of ground glass, and the rest ordinary plain glass. It will give us a side light of about 5 feet depth, then will come the coping space of 2 feet blank. The rooms will provide us with a studio, length of 33 feet, but we propose to partition off a small portion at one end for a printing room. This, however, will be arranged so that the camera can be taken back to the full 33 feet, when required, for groups, &c. The premises are in the principal business street here, and are in all other ways as convenient as it is reasonable to expect in such a position. We shall have a north light, with excellent waiting rooms, &c., on the first landing, and studio and dressing room above."—The coping will be a great nuisance, as it breaks the light where it is most wanted. However, "what can't be cured must be endured." We would suggest that the top light be increased a couple of feet, making it equal to the side, that will give greater scope for "coping" with the difficulty. With the alteration the dimensions of the glazing will be right.

**ENLARGED NEGATIVES.**—UZERCHE says: "I have been attempting the making of enlarged negatives for printing in carbon, but, so far, with very little success. The carbon process, given a decent negative, I find easy enough, and its results are far better than anything obtainable by direct enlarging on bromide. But the difficulty is the enlarged negative. I have tried enlarging, both with a Hume Cantilever and oil, and also with an ordinary camera and daylight; I have tried making a small transparency by contact (both carbon and on lantern plates), and enlarging that to get a negative; and I have tried making a large transparency direct, and the enlarged negative by contact. My negatives are quarter-plate snap-shots, but taken in brilliant light with the full aperture of a Goerz lens and the slowest speed of a Thornton-Pickard shutter, are not at all under-exposed. They are, however, rather hard, as they were developed with 3 grains of pyro and 2 grains of bromide of potassium to the ounce. The principal defect of the enlarged negatives has been insufficient density. I have tried strengthening the developer and prolonging the development without materially improving matters. May I ask the following questions? 1. Which is the easiest way to coat glass with a substratum for carbon transparencies, i.e., what mixture and how applied? 2. Using ordinary tissue, how much further should printing be carried for a transparency than for a direct print? I have a Wynne's print meter, and so can estimate it exactly. 3. Using an ordinary plate for the enlarged negative, which is preferable, A, B, or C? 4. Can you give me any hint as to why I fail to get density in the enlarged negatives? They are not one-third as dense as the original quarter-plates."—1. Dissolve 1 ounce of good gelatine in a pint of water, then add sufficient bichromate of potash, in solution, to give a pale yellow colour. Pour this over the plate and stand up to dry in full daylight. 2. From two to three times. 3. The ordinary brand of A. 4. Probably the transparencies are too weak. Unless the transparency is of good density, it is impossible to produce vigorous negatives. Aim at getting vigorous transparencies to begin with.

## EX CATHEDRA.

THE Annual General Meeting of the Royal Photographic Society, on Tuesday evening last, attracted a room full of members. The proceedings passed off with their customary tameness; and there was no manifestation of discontent, on the part of professional photographers, with the Society's policy and performances. Indeed, there were not half a dozen professionals present. The ballot for the Council election, as will be seen by our report elsewhere, resulted in no very marked surprises. Messrs. Child Bayley, J. A. Sinclair, and E. J. Wall supply the new blood—if new blood it can be called—and of the old Council Messrs. R. W. Craigie and John A. Hodges were not re-elected. We regret the disappearance of both gentlemen, and trust it is only temporary. Having sat with them on the Council for the last twelve months, we had many opportunities of knowing that they rendered valuable service to the Society.

Two hundred and fifty members voted, but thirty-three of the balloting papers were invalidated for various reasons.

Mr. Sebastian Davis earned the thanks of those present by alluding to the all but universally admitted fact that the Society's exhibitions have of late not been so representative of good technical portrait and landscape work as in former year. We have had evidence of the existence of such a feeling from all parts of the country laid before us. To construe that feeling into a desire for the exhibition of "show-case work" is absurd, although if show-case work is good enough—and why should it not be?—what can be the objection to its being hung? We should be very sorry to see the show-cases of the humblest photographers disfigured by some of the dreary monstrosities that adorned the walls in Pall Mall last autumn. One or two photographers happily placed at "the top of the tree," with the accompanying delights of the frequent receipt of medals, and requests to act as Judges at Exhibitions, may be content with things as they are, and therefore can hardly be expected to sympathise with any proposed changes; but we are convinced from wide inquiry that Lord Crawford voiced a general feeling when he pointed out that only one school of portraiture was represented at the Exhibition, and that it was susceptible of being made far more catholic than it has been in the past.

WE learn from a note in a daily contemporary that that energetic photographic student of archæology, Sir Benjamin Stone, M.P., who has recently returned from Rome, received permission while in the Eternal City to photograph some of the many thousands of manuscripts and parchments which are stored away in the famous library at the Vatican. The hon. member made a selection of those relating to England, which were principally of the eleventh, twelfth, and thirteenth centuries, and is now busily engaged in the work of translating these most interesting documents. Sir Benjamin was assisted in his researches by the chief librarian at the Vatican, his two assistants, and the two gentlemen representing the British Record Office, who are permanently engaged in cataloguing these important works.

MR. F. N. BRODERICK, the well-known photographer of Ryde, Isle of Wight, recently gave a lantern entertainment in the Town Hall, Ryde, which was marked by novelty and success, and, from the description we have read of it, appears to have well earned the complimentary term of "extraordinary" that

was subsequently applied to it. He showed 130 lantern slides from his own photographs, obtained on the Ryde football field and elsewhere. The slides took Mr. Broderick four months to prepare, and apparently his hand camera followed the Ryde team through all the vicissitudes of a season of out-and-home football matches. The pictures were humorous and instructive to local admirers of the game. They included portraits, illustrations of "points" and interesting incidents, groups, and so forth. Mr. Broderick's photographs were so highly praised that we hope they may be seen on this side of the Solent ere long. The photographic illustration of a lecture on so popular a game as football is an occurrence unusual enough to deserve particular notice.

\* \* \*

COMPLAINTS are frequently made in our columns by operators and assistants who are unable to obtain the return of specimens submitted with applications for employment, and it will, no doubt, interest both sides to the undying controversy to know that by a recent jury's verdict the loss or detention of specimens renders an employer, to whom they have been sent by a would-be *employé*, liable to considerable damages. Last week, at Birmingham, an action was brought by Mr. Charles Butfield, an art printer, to recover damages from Messrs. Cond Brothers, printers, of Birmingham, for the wrongful detention of certain specimens in art printing which, it was alleged, were sent by the plaintiff on July 5 last year in reference to a situation the plaintiff was applying for. The specimens, plaintiff stated, were made up into a flat brown-paper parcel, in which was also enclosed a letter giving references, and posted on July 5 last. Defendants had admitted receiving the letter, but denied having received the specimens. The plaintiff therefore now sought to recover compensation for the loss of these specimens, which he was unable to replace, and which were of considerable value to him as proofs of his skill as an art printer. Evidence was given by a postman named Dowell, who was employed at the Birmingham G. P. O., to the effect that he delivered on July 6 a similar parcel as was described by the plaintiff to Messrs. Cond Brothers. He produced his way-bill to show that the parcel had been received by a Miss Martin, who was then in the defendants' employ. The defence set up was a denial that the parcel in question was received, it being asserted by Mr. Cond that the specimens had never reached his hands. The letter plaintiff had mentioned as containing reference was delivered in an envelope by the ordinary post on July 6, but no specimens were ever received, and, if posted, must have miscarried. The jury returned a verdict for the plaintiff, damages 75*l.*, and judgment was entered accordingly. This case is of the greatest importance to photographers and photographic assistants, and, if borne in mind by both classes, will unquestionably minimise or lessen the causes of dispute between them. The wilful detention of an operator's specimens is a cruel thing, and we are glad to see that a jury, in the analogous case above quoted, takes the view that such conduct renders an offending employer liable to damages therefor.

\* \* \*

We are indebted to a friend, Mr. C. H. Crosby, of Chicago, for a copy of the *Sunday Times-Herald* of Chicago, of January 22, in which three columns of very small type are devoted to a characteristically glowing piece of American journalese about "the wonders of colour photography," and the "possibilities of this marvellous discovery in the educa-

tion of mankind in the arts and sciences," which are declared to be "almost beyond conception." Two or three facts stand out from the mass of high falutin. (1.) The Secretary of the Chicago Society of Egyptian Research sailed for Africa recently, equipped with the means of taking colour photographs in the land of the Pharaohs. (2.) A colour-photography academy is being built in Chicago for the use of professors and students. (3.) The process that is to achieve such mighty wonders in Egypt, Chicago, and other parts of the world, through the agency of a Mr. D. K. Tripp, is that known as McDonough's, and McDonough was anticipated in his discoveries by Ives and Joly. Three-colour lantern slides are now fairly common objects of the lecture-room on this side of the Atlantic, and colour half-tones are, of course, familiar to everybody by now. The Chicago people are very belated in their ideas about colour photography. What they are attempting to boom is not new, and we really doubt whether three-colour lantern slides of Egyptian subjects will be as effective and satisfactory as the series of the Photochrom Company's mechanically prepared Egyptian prints, which are obtainable at a few shillings each. Unless we are greatly mistaken, we can perceive the hand of the company-promoter in the Chicago outbreak of colour-photography academies, and all the rest of it.

\* \* \*

AMONGST new publications that have reached us reference is deserved by *The Poster Collector's Circular*, published by Messrs. P. G. Huardel & Co., 18, Cranbourne-street, Leicester-square, price 3*d.* monthly. The circular contains many reproductions of native and foreign posters, and the letterpress notes are bound to be interesting to the votaries of a very attractive cult. Dudley Hardy's theatrical posters are purchasable at prices ranging from 1*s.* to 5*s.* 6*d.* *The Universal Provider and Shopping News* has its scope indicated by its subtitle, "A Journal for Buyers and Dealers." It is published weekly at 68, Farringdon-avenue, E.C. One of its early numbers contained an article on the defects of the British patent system, which it criticises very unfavourably. Where, it asks, is the protection to the poor inventor? The system is a device and a snare, and practically perpetuates a department to receive fees only, while the patentee must depend upon his own exertions and the length of his purse to successfully cope with those who designedly seek to wrest from him any benefits he may hope to derive from his invention. It is, in a word, discreditable to our nation, and the sooner a more honest system is established the better it will be from a moral standpoint, and become, as it ought to become, a real practical help to the rising generation of inventors. We have expressed exactly similar sentiments over and over again, and are glad to find them shared by our young contemporary.

\* \* \*

The prospectus has been issued of the British Mutoscope and Biograph Company, with a capital of 300,000*l.*, formed to acquire the business of the Mutoscope and Biograph Syndicate, who for eighteen months past have done much to popularise animated photography at places of entertainment, &c. The list of applications closed on Wednesday last. Interest in animated photography seems to us to be by no means on the wane. Writing on the subject at the conclusion of our article in the ALMANAC for 1898, we remarked that it appeared to us that this branch of photography was destined to have something

more than a transient existence, and what has happened since we then wrote (in October, 1897) fully bears out our opinion of the stability of the hold of animated photography in public favour.

\* \* \*

We have received from Mr. William Tylar, of Birmingham, a list and sample of his series of penny stereoscopic (paper) slides. The latter is a view of Zermatt, and is excellent value for the money, regarded either photographically or stereoscopically. Mr. Tylar claims to hold the largest variety of stereoscopic slides in the Midland Counties, his views of the British Isles alone amounting to 4000. He has a series of stereoscopic subjects taken by Royal command. Mr. Tylar finds that interest in stereoscopic work is on the increase—a fact that we are pleased to learn. The wide distribution of cheap and good stereoscopic slides should help to promote the growth of this class of work among professional photographers, for it is probable that, by contemplating properly prepared binocular slides in the stereoscope, the public may be the more easily induced to patronise stereoscopic portraiture, a branch of photography the resuscitation of which we have often pleaded for.

#### RADIATION OR CHEMICAL ACTION AS A FOG-PRODUCER.

THE interesting experiments by Dr. Joachim Sperber, described in our issue for February 3, taken in conjunction with those of Dr. Russell, on the actinic radiation from supposedly chemically inert bodies and its action upon dry plates, raise many important questions, and it is not a little singular that they remain virtually the only definite experimental records of such action that must be capable on occasion of seriously influencing photographic results. It may perhaps be considered that Dr. Sperber's two experiments are not sufficient for us to accept as facts, first, that turpentine vapour has no chemical action upon dry plates *qua* vapour; and, secondly, that it can, however, so act upon that part of the universal ether in its own vicinity as to cause it to so vibrate that it will act similarly to light upon the sensitive silver film. The point that would first strike the investigator when examining the results of Dr. Sperber's two experiments is the conclusion that turpentine vapour, acting for a period of four or five days upon some of the dry plates, should be without result, especially when the chemical properties of the liquid in question are considered. Turpentine is well known to absorb oxygen from the atmosphere, a process of slow combustion, in fact, taking place with the production of a certain amount of ozone; *a priori*, some slight amount of reduction of the silver haloids might naturally be expected to result and to show upon the application of the developer. Possibly other experimenters may take up the matter, and we await with interest further results, either from them or from Dr. Sperber himself, as promised.

The present seems a suitable occasion to refer to another phase of the subject, the more so that some recent experiences have a very practical lesson to inculcate. We had occasion to test a new hand camera, and in the course of a day we exposed its whole contents, a dozen plates, in the usual sheaths. Development was not undertaken for several days; but, when the plates were developed, all were hopelessly fogged. This was so unexpected, so unaccountable, that it seemed little less than mysterious. There was certainly no light leakage in the camera; the plates were put in their sheaths in a safe light

and developed similarly in each case, indeed under circumstances in every way identical with those under which hundreds of other plates had been safely operated upon before, and have been since. The conclusion we came to was, that the camera, new from the maker's hands, and smelling strongly of the varnish used to blacken it, was defective because of the vapour from that varnish. We took out the sheaths and placed them before a fire, leaving the camera open, for the varnish solvents to become thoroughly evaporated. When all was put together again after a few days' exposure, and once more tried, everything went well and not a trace of fog was noticeable. This experience might be put down as a pure coincidence except for a remarkable confirmation of our views. A well-known professional photographer had occasion to develop for a lady amateur a dozen plates (put in their places by that gentleman), and exposed in an identically similar camera, also brand new. To his surprise all the plates were fogged, and it was not till we compared notes that the conclusion was inevitable to him that the fog was caused by exposure to the vapour from the half-dry varnish. It could not be ascribed to Dr. Sperber's ether vibrations, for the fog was equal all over the plates, and, about as near as the eye could judge, equal in intensity on each plate, though various lengths of time must have elapsed for each individual plate to be exposed to direct radiations.

We have another somewhat similar effect to describe. Quite recently a photographer of our acquaintance had a day's work with eighteen  $12 \times 10$  plates. Six of these had been in the slides for over a month, and, of these six, five were exposed and one unexposed. When the five, together with another plate of the same subject (only placed in the slide the same day), were developed, the latter was perfect, but the five were ruined by a band of fog extending for a width of two or three inches across the whole of one end of each plate. There seemed no possible explanation, for the first thought, that the slides might leak light at the hinges, proved to be untenable. Then the possibility of some emanation from the light-proof cloth used for hinging the pieces of the flexible back together, being the *fons et origo mali*, occurred to our friend's mind. Luckily, there was an unexposed plate remaining in one slide, and it had been there for the same length of time as the five. It was placed, unexposed as it was, in developer, and in a few minutes' time there appeared a broad band of reduction just opposite to where the cloth of the hinged back was cemented. Now, we are not able to state either the constituents of the varnish used on the hand cameras, nor yet that used for the light-proof cloth, nor of the cement by which it was attached; but this we do feel certain about, that, in each of the cases we describe, some agent was at work that produced fog. Whether it were ethereal vibrations, as suggested by Dr. Sperber in his experiments, or whether it were simply a case of chemical reduction by a deoxidising agent in the varnish vapour, cannot be considered demonstrable to a certainty. But that certain samples of black varnish can give off emanations resulting in fog to plates exposed long enough to their influence is incontestable, and is a fact to be remembered by practical workers.

—♦—

**Occult Causes of Plate-fogging.**—The interesting paper on the cause of plates fogging when exposed to turpentine radiations or emanations which appeared in a recent issue—the subject being one to which we have referred above—brings into recollection many isolated experiments which have been related from time to time in these columns: the flash of light when withdrawing a plate from

the developing solution, the possible radiation from the paper strips separating the plates in their packages, and so on. That luminosity from simple means may be brought about has long been known, the old experiment of striking two lumps of sugar together in the dark is an example. The luminosity of sugar was the subject of a paper at the last meeting of the British Association. The same subject is referred to by Mr. Thomas Steel, of the Colonial Sugar Refinery Company at Sydney, and, from the examples he gives, it may be readily imagined that other equally simple means of bringing about luminosity, and, in consequence, fog, may occur in the handling or storage of dry plates. Mr. Steel points out that sugar as delivered from a hopper in its manufacture is always luminous in the dark. A heap of loose sugar struck with a shovel, a small bag of sugar set hard in dry weather scraped with a spoon, and so on, will in each case produce luminosity.

**A New Projection Microscope Lens.**—In the *Journal of Applied Microscopy* is an account of an objective of 20 mm. focal length and 0.95 numerical aperture. It is stated to be a copy of a 5 mm. apochromatic, the diameters and radii of the latter being increased four-fold. Dr. White's theory is that with a magnifying power of a thousand, if a certain aperture is needed for proper definition, a similar aperture will be needed for projecting an image on the screen, even if it be obtained with a three-quarter inch objective and a projection eyepiece.

**A Method of Rectifying Prismatic Spectra.**—We read in *Nature* that in Professor M. B. Snyder's pamphlet upon the Harvard Astrophysical Conference there is an account of the ingenious method of Mr. E. S. King of converting prismatic spectra into normal spectra. To do this, the original plate is inclined to the plate on which the copy is to be made by an amount calculated to make the scale exact for three points in its length, while at the same time maintaining good focus. As illustrations, he showed several stellar spectra compared with Rowland's map of the solar spectrum. Professor Pickering said that the method was perfectly general, and all scales were thus reproducible. This description is rather vague, but it apparently refers to copying in the camera, or other analogous means, the negative to be copied, and, in consequence, the spectrum, being thus shortened, as it were, by reason of the tilting of either the plate by the swing back or the negative itself.

**Physiological Opacities to Röntgen Rays.**—At the Royal Dublin Society's last meeting a preliminary note was forwarded by Mr. A. W. Henley upon a method of measuring the relative opacities of various organic substances to the X rays. Some of the substances experimented with were bone, muscle, and fat, and the relative opacities of these bodies were, respectively, 4, 2.5, and 1. The method of procedure was to prepare wedge-shaped pieces of the various structures, place them side by side, and, after finding a point in each wedge equal in colour, measure the thickness of the wedges at the respective points. This method presupposes a degree of uniformity in the Röntgen radiations, which all practical workers know does not exist. Quite recently we saw a large collection of skiagraphs of the human limbs and thorax, in the majority of which there was scarcely any difference in the opacity of bone and flesh. An important point in Röntgen-ray work is to have control over the penetration of the rays.

**Competitions.**—During the past few years photographic competitions seem to have been the order of the day amongst illustrated papers, sensational advertisers, manufacturers, and some of our photographic contemporaries. The subjects offered in competitions have been varied, though not greatly; but we imagine that those inaugurating these competitions, after a few years, are

somewhat at a loss for a subject. *Spring, Summer, Autumn, Winter, Solitude, Rest, Sunset, &c.*, have been done *ad nauseam*. There is one subject we would suggest for competition to those at a loss for subjects that we do not remember being offered before, namely, examples of technical photography. Of late years that seems to have been entirely overlooked at exhibitions and also in competitions.

**London and New York Weather.**—Some weeks back we gave some hints for the avoidance of winter troubles in photography, also as to how photography in winter might be turned to a profitable account by professionals. So far they have been of no value, though this time four years ago we were involved in an arctic winter. Friday last was a record day for heat in February, for the thermometer at the Meteorological Office registered 68°, the highest it has reached for more than fifty years. Curiously enough, the day in New York was also a record one; but in the opposite direction. There the temperature, officially stated, was six degrees below zero; and it is stated that, in more exposed situations, it touched some six or eight degrees below that. According to authentic records, it is said that only three times has it been as cold as that in February, but never colder. Such, however, were the opposite conditions of the weather, on Friday, on the two sides of the "herring pond." Possibly London photographers have not envied their American *confrères* so very much, after all.

**Gift to the London County Council.**—At its meeting last week the London Council decided to accept the gift of Mr. S. Prout Newcombe of his natural history collection and library. The collection consists of over twenty thousand objects and a considerable mass of literature on the subject. It may interest some of our readers to know that Mr. S. Prout Newcombe was a photographer. Indeed, he may be said, in conjunction with Mr. C. W. Quin, trading as the London School of Photography, to be the pioneer of cheap photography on paper, doing portraits on paper the quarter-plate size at half a crown, 5×4 three and sixpence, and the half-plate at five shillings—duplicates half these prices. During the late fifties and early sixties, Mr. Newcombe had several places in London and the provinces—Sheffield, Manchester, and Liverpool. In his price-lists it was stated that the negatives were kept for a month—or may have been three months—during which time they might be purchased by the sitters at the same price as duplicates. At that early period it will be seen it was an established and recognised fact that the negative was the property of the photographer, and could only be had by the sitter by purchase. We do not remember that this early "custom of trade" has been quoted in the Law Courts when this once-vexed question was contested.

**The Paris Exhibition of 1900.**—The position of the British Commission on this Exhibition has been considerably improved by a Treasury grant increased from 75,000*l.* to 130,000*l.* But it is said that the work of arranging for the British representation can only proceed slowly by reason of the dilatory action of the responsible French authorities. With this increased grant it is to be hoped that photography will be better represented than it would have been with only the smaller sum, and that greater facilities will accrue to the exhibitors in the matter of transmission of exhibits, &c. This Exhibition is to be a big thing—the biggest thing yet, and it is hoped that it will be carried out as projected, and completed fairly within its closing time; but, if the rumours are correct about the dilatoriness of the executive, that at present seems doubtful. The Chicago show a few years ago was a big thing, but it was scarcely completed at its close. An astute Yankee said of that before it was opened, "We mean to make a big thing of it, but I guess we have cut about as big a slice as we can eat." We hope our French neighbours have not cut a bigger slice than they will be able to get through, at least fairly within the opening time.

## JOTTINGS.

EXIT Bennetto: exit Sellé; *exeunt omnes!* To my personal knowledge the Sellé process of colour photography has been hawked round among the company-promoters for the last two or three years, only to be dropped or passed on. Glancing down the reported bankruptcy proceedings in the newspapers last week, I saw that the gentleman who was the very last to take up the ominously named Sellé method figured as the object of a public examination before a Registrar. Now, I am wondering where the Sellé process will bob up next. I first met it—but stay, I think I'll keep my colour photography reminiscences for my autobiography. They are much too funny for these austere columns.

Mr. James Burns, who lately read a paper on "Pictorial Photography: its Difficulties and Pleasures," before the Edinburgh Photographic Society and which is printed in the JOURNAL for January 27 last, will find accuracy of statement an acquisition in the preparation of any further literary efforts that he may design to read to Edinburgh photographers. His name is quite new to me, and I shall not mourn if I never see it again while its owner is at such little pains to verify his references, as the following extract from his paper shows him to be: "A writer in one of the oldest photographic journals seems to find the whole sweetness of his life in abusing the pictorial school; and his great ambition is to write the epitaph of that school, or don the mantle of Gibbon and astonish the world with a new Decline and Fall." It is on record that I look forward to one day writing the epitaph of the institution known as the Photographic Salon; but this is a very different thing to "abusing the pictorial school" and writing its epitaph. Mr. Burns evidently doesn't know what he is talking about; but that is no excuse for utterly erroneous statements when the means are at hand for avoiding them, in the file of THE BRITISH JOURNAL OF PHOTOGRAPHY which I believe his Society possesses.

"Rex" and "Fogged Light" in the Answers to Correspondents columns of the last two issues, have raised the question of south-light versus north-light studios. I may refer both gentlemen to a paper, entitled "Is the Present Construction of Photographic Studios Wrong in Principle?" by the late W. H. Harrison, printed in this JOURNAL for May 19, 1893. In the course of that paper Mr. Harrison raises an objection to north-light studios on the ground of the floating particles in the air interposing a reflecting screen between sky and studio. He suggested, indeed, the reflection of the light from a whitewashed wall, the studio having a southern aspect, glazed high up. The rays falling on the wall would give the chief light for the illumination of the sitter. There are several more interesting points in the paper, which is well worth perusing by others as well as the two correspondents who have reminded me of the matter.

The recently published letters on the subject of the Royal Photographic Society and professional photographers included one from Mr. F. M. Sutcliffe, who, in his reference to the value of the Society's Fellowships (p. 62), says that, when the higher dignity was created, the Society was not particular what the Fellow knew of photography so long as he had two guineas in his pocket. This is not, perhaps, the fairest way of stating the case. When the Fellowship scheme came into force, existing members were naturally given the privilege of opting for the higher grade; but, since then, admission to Fellowship has only been by election on evidence of qualification. To-day, at any rate, Mr. Sutcliffe may take it from me that a man does not so easily acquire a Fellowship as he seems to suppose. A fairly severe ordeal has to be passed first.

I grant that the Fellowship has here and there gone into hands from which it might have been withheld; but the mistake is not likely to be repeated. From the list of 250 Fellows lately published perhaps a dozen or so names could well be eliminated; but it is a very good and weighty list on the whole, and it includes such professionals as Harvey Barton, R. Beckett, F. T. Beeson, H. W.

Bennett, Thomas Birtles, S. B. Bolas, F. N. Broderick, Warwick Brookes, John Bulbeck, J. C. Burrow, W. J. Byrne, T. H. Chaffin, J. H. Coath, Henry Cooper, C. E. Corke, John Davis, G. T. Y. Dickinson, T. J. Dixon, T. Fall, J. H. Gear, William Gill, F. M. Good, W. E. Gray, William Grove, F. Hollyer, C. B. Keene, E. D. Lavender, H. Bedford Lemère, F. and T. Marsh, G. W. Morgan, A. F. Mowll, S. Glen Payne, G. Pendry, Douglas Pym, E. Scamell, J. B. Scott, F. Thurston, W. M. Warneuke, G. Watmough Webster, Alfred Werner, and H. R. Yeo—not by any means a bad or unrepresentative list, in which the honoured name of Frank Sutcliffe might very well find a place. What sayest thou, O' Sage of Whitby?

A gaslight developing paper is such an obvious modification of the gelatino-bromide printing process that now we have it with us from five different sources, one is all the more surprised that it was not thought of years ago. Putting out of sight the very prolonged exposures needed to secure coloured deposits by development, it is remarkable to note the wide range of sensitiveness between the papers when used to secure black images. Light, negative, distance of flame from frame being the same in both cases, 20 seconds at one end of the scale, 200 seconds at the other, that is, a ratio 1:10, represent the rapidities of the fastest and slowest of these papers with which I have at present worked. From the standpoint of the casual worker, who only needs now and then to produce a few prints, the slower papers, with their greater freedom from liability to fog, must possess the balance of advantage, while to a professional man, with whom time is an object, the quicker papers must necessarily appeal. I am surprised that the noisy advocates of "personal control" in print-making have not perceived that these gaslight papers, which are amenable to brush development, supply what they have long been clamouring for, especially as regards colour of deposit, which is entirely under command. And, as with bichromated gum, you may make it as difficult as you please to get two prints alike by gaslight development, it is the ideal Salon process. Mr. Craigie, now's your chance!

The Yorkshire Union of Photographic Societies has very early commenced to taste the bitterness of dissent, for the withdrawal of such a powerful and ably officered organization as the Leeds Camera Club (whose well-reported proceedings have for a long time past supplied readers of this JOURNAL with some really valuable information) is a serious blow to the scheme before it is well on its legs. However, the defection of Mr. Warren's merry men (the precise reasons for whose abstention from the Union can, of course, only be properly perceived by those on the spot) should spur the Bradford men on to renewed exertions in establishing the Union. But I must confess that, the more distinctly that scheme takes shape, the plainer and more formidable do the difficulties of administration become. If the Union can successfully run and manage both a voluntary and paid lecturing staff at once, it will take credit for a great achievement. Still, they do big things in Yorkshire, and I wish the Union success.

It appears that the Leeds Camera Club has not only held aloof from the Union, but has resigned from the Affiliation of photographic societies. This is quite one of life's little ironies! Last year and the year before the Affiliation was "all Yorkshire," as I heard it recently put by a prominent London photographer; to-day Yorkshire and the Affiliation are not on speaking terms. Here there is obviously scope for the pencil of a clever cartoonist or a comic versifier! Mr. Warren himself might try what he could do in the matter. Such an epidemic of retirements, resignations, and shan't-play-any-more-ism at any rate supplies the photographic world with a little much-needed amusement, and therefore does some good. Joking altogether apart, however, I am sorry the L. C. C. has dropped out of the Affiliation. The latter is now happily in the firm hands of Colonel Waterhouse—an experienced, tactful, and conciliatory administrator, who may be depended upon to direct the scheme to the best advantage of the contributory societies and the R. P. S. and who,

he had been at the head of the movement all along, would not, I am sure, have allowed so much friction to occur as has unfortunately been the case in the past.

A rumour reaches me that at the forthcoming meeting of the Convention at Gloucester in July the pictorial exhibition, which has hitherto been a welcome feature of these pleasant and useful gatherings, is in danger of being abandoned. May I suggest that, if the President-elect, Mr. William Crooke, could see his way to organize a representative exhibition of pictorial portraiture, a division of photography of which he is the admitted head, it would be very highly appreciated, not only by Conventioners but by the people of Gloucester and neighbourhood. There would be some trouble and labour in organizing and hanging the exhibition, no doubt, but Mr. Crooke should surely find many willing helpers in the work. At any rate it seems a pity to abandon the exhibition idea, and at the same time to decrease the number of the business meetings, as is proposed to be done next July.

COSMOS.

## ON THE USE OF TELE-PHOTO LENSES IN ASTRONOMICAL PHOTOGRAPHY.

[Translated from the *Photographische Correspondenz*.]

In the November issue of this periodical the attention of a large circle of readers is directed to the use of the tele-photo lens for the study of the heavens, but without any explanation of its applicability to the purpose. As I am rather intimately associated with the construction of the tele-photo lens, and as the works bearing my name introduced it as an optical instrument for astronomical purposes, and have manufactured it for many years as the photographic telescope, I think it important that erroneous opinions should not be created concerning the use of these telescopes. Hence these remarks.

To form an idea of the work it may accomplish, we will first consider what objects in the heavens are open to photography. They may be classified in two primary divisions: those depicted as points, and those as surfaces. To the former belong all the fixed stars excepting the sun, and to the latter all the planets with their satellites, the comets, nebulae, double stars, &c.

For those images rendered as points, the aperture of the objective with which they are photographed need only be considered, since the objective with the largest aperture will define the smallest stars in the absence of other disturbing causes. If we remember that the stars send out light in all directions, and that the portion of the light which reaches us may be conceived as a beam of parallel rays, then, popularly speaking, all the parallel rays falling upon the objective will be united and form a point. The larger the aperture of the objective, the brighter will be the point, because it is formed by a larger number of rays of light. The distance of the point of convergence from the objective is of no importance. Consequently, the brightness of the image does not depend upon the focus, but upon the aperture of the objective. The facts are somewhat modified by the circumstance that lenses do not form mathematically perfect points of light, and the theory of diffraction also teaches us that an increase of light does not under all conditions add to the brilliancy of the image. But we will pass over these factors, as we are not concerned with the rendering of images as points, for it would be absurd to artificially lengthen the focus of an objective for photographing objects, when their representation is not influenced by length of focus. Tele-photo lenses are objectives of this description, as we shall subsequently see.

When we come to the representation of objects with dimensions, the focus, as well as the aperture, of the objective plays an important part, because it determines the size of the image. With an objective of given aperture, only a definite quantity of light is available for the formation of the image, and it is evident that, of a number of objectives with the same aperture, that with the shortest focus will give the brightest image. We must therefore distinguish between heavenly bodies of low and high luminosity in considering those of magnitude. The former should be photographed with objectives of short focal length in proportion to aperture, and principally comprise the nebulae, comets under certain conditions, and many double stars, but we will also leave these bodies out of consideration, because they emit too little light to be of any use for photographing with tele-photo lenses.

The luminous heavenly bodies of magnitude are those which particularly interest us, namely, the sun, moon, and planets. As we have seen,

the size of the image depends upon length of focus, and larger images can only be secured by using very long foci. With ordinary objectives, focussed for infinity, the distance of the image from objective is about equal to the focus, and a camera is therefore used equal in length to the focus. But this necessitates very expensive and unwieldy instruments when rather long foci are used. If, however, a negative lens is placed in the cone of rays formed by such an objective, its focus will be considerably lengthened beyond the distance between image and objective, and in this manner a tele-photo objective is formed with a tube much shorter than the focus; but to this external advantage there is a corresponding internal disadvantage, namely, the diminished intensity of image. In using tele-photo lenses it is therefore necessary to confine oneself to the heavenly bodies forming images of magnitude, or, as we shall subsequently see, to one only. An immediate consequence of the low intensity of tele-photo lenses is the necessity for long exposure, in which case atmospheric disturbance has much influence, as it is magnified in like manner, and the image becomes very poor; but much may be done by exposure and development to counteract this.

We will leave these difficulties and consider what limits are imposed upon the use of the tele-photo lens by the laws of nature. For this purpose we will take practical examples by setting ourselves the task of photographing the following bodies:—

- I. Double stars.
- II. Planets.
- III. The moon.
- IV. The sun.

### I.—DOUBLE STARS.

In photographing double stars we, of course, desire to obtain them distinct from each other.

In the following table the distance of image at various foci is given for certain well-known double stars. It will be seen that it is only possible to separate close double stars by means of large tele-photo objectives. The stars are always represented of a certain diameter upon the plate, and we will take this as 1 mm. With a tele-photo objective of 50 m. equivalent focus, or about 5 m. length,  $\zeta$  Bootis with 0.8" separation would be well defined. Under similar conditions a tele-photo objective of 5 m. focus would only separate stars of 5" angular distance or more.

I have placed the limit of separation rather low, or, rather, the diameter of the image of the stars somewhat high, because the image obtained with a tele-photo objective of 5 m. focus can never be as good as that obtained with a single objective of the same focus but larger aperture. I have repeatedly seen pictures of double stars, distinct from each other, although only 8" apart, and these were taken with an objective of 33 cm. aperture and 4.8 m. focus made at our works, but very short exposures were given. The exposure would be very considerably longer with a tele-photo objective, and the image consequently larger. We may therefore conclude from these considerations that tele-photo objectives are of little use for photographing double stars unless the apparatus is of very large dimensions.

TABLE I.

Stars.	Separation.	Distance between the centres of both stars, in millimetres, at the foci of the tele-photo objective.				
		5 m.	15 m.	30 m.	50 m.	
	sec.	mm.	mm.	mm.	mm.	
$\zeta$ Ursa Major (Mizar).....	14.3	0.35	1.04	2.1	3.5	
$\gamma$ Andromeda .....	10.3	0.25	0.75	1.5	2.5	
$\pi$ Bootis .....	6.0	0.15	0.44	0.87	1.5	
$\gamma$ Virginis .....	5.0	0.12	0.36	0.73	1.2	
$\alpha$ Corone .....	4.0	0.10	0.29	0.58	1.0	
$\zeta$ Ursa Major .....	2.0	0.05	0.15	0.29	0.48	
$\zeta$ Bootis .....	0.8	0.02	0.06	0.12	0.19	

### II.—PLANETS.

Those who wish to photograph the planets will chiefly desire to secure surface detail, in order to deduce the time of revolution or for the purpose of studying the details themselves. From the following table we may see how large the various planets are rendered by tele-photo objectives at certain foci. In the first column the apparent diameter of the planet is given when nearest the earth; in columns 2 to 5, the diameter of the image corresponding to apparent diameter of the planet. In columns 6 and 7, the aerial image, and the enlarged apparent aerial image through an ocular, as rendered by a telescope of 2100 mm. focus and 400 times magnification.

This table shows that only the larger tele-photo objectives render the planets of sufficient diameter to permit of detail being seen. A telescope of 2100 mm. focus cannot be considered large for observing the planets; but they are seen seven times larger than they can be photographed by a tele-photo lens of 15 m. focus, which would be of about the same outward dimensions. The photograph would have to be enlarged seven times to show the same detail that the eye would see through the telescope. Those who know how much a photograph loses in sharpness and clearness, even when enlarged to a small extent, will be able to understand that planet photographs will not bear so much enlargement when taken with a tele-photo objective, and that it is impossible to use the tele-photo objective for the surfaces of the planets to supersede drawing by means of the telescope. If photographs of the planets are wanted of the same size as these bodies are seen through telescopes of moderate dimensions, the tele-photo apparatus must be so large that it would be difficult to use.

TABLE II.

Planets.	Dia- meter.	Diameter of image at foci.				Telescope of 21 m. focus and 400 times magni- fication.	
		5 m.	15 m.	30 m.	50 m.	True aerial image.	Apparent aerial image.
	Sec.	mm.	mm.	mm.	mm.	mm.	mm.
Mercury ...	13	0.32	0.95	1.89	3.15	0.13	6.4
Venus .....	65	1.58	4.73	9.45	15.76	0.66	32.2
Mars .....	26	0.63	1.89	2.78	6.30	0.265	12.9
Jupiter ....	51	1.24	3.71	7.42	12.36	0.519	25.3
Saturn .....	21	0.51	1.53	3.05	5.08	0.214	10.4
Uranus .....	4.7	0.11	0.34	0.68	1.14	0.048	2.3
Neptune ...	2.7	0.07	0.21	0.39	0.65	0.028	1.3
	1	2	3	4	5	6	7

To photograph Saturn, for example, in the same manner as Herr Leo Brenner has drawn it in vol. 145 of the *Astronomische Nachrichten*, the focus would have to be 450 m. Even if so strong a negative lens were employed that the entire length of the photographic telescope did not exceed one-twentieth of the focus, it would still be necessary to use a tube 22.5 m. in length.

### III.—THE MOON.

The moon is, doubtless, a more favourable object than the planets for the tele-photo objective. Even if the proportions of the direct photograph were the same as the image seen through a telescope, this would not be objectionable, because the details of the moon are so large and distinct that they may be seen with a very small telescope; but the image is so weak when formed by a tele-photo objective with large magnification that long exposures are necessary. Under such circumstances, the movement of the moon in declination is frequently a disadvantage. This cannot be corrected by the clock attached to the instrument, and it is sometimes so great that photography becomes impossible. If the movement in declination, for example, amounts to 2° 50' in twelve hours, then during an exposure of eight seconds, with a tele-photo objective of 32.3 m. equivalent focus, a point would traverse 29 mm. upon the plate, which means that the entire image would be void of detail. But an exposure of eight seconds would be, in my opinion, decidedly too short. It is, however, possible to avoid this difficulty by taking photographs when the movement of the moon in declination is small, which may be ascertained from the *Berliner Jahrbuch*; but this curtails the use of the instrument considerably. It is best, in photographing the moon, not to use a very long focus, and to enlarge the negative as much as possible for use as a guide in making drawings by means of the telescope. It is, therefore, evident that photographs of the moon taken with the tele-photo objective cannot be used as substitutes for drawings, but they are of supplementary use, and in this way the tele-photo objective may be of value for studying the moon.

### IV.—THE SUN.

The heavenly body most suited to photography with the tele-photo objective is decidedly the sun. It is so luminous that instantaneous exposures may be made even with the slowest of objectives. The advantage of the tele-photo objective, very long focus in comparison

with aperture, may therefore be utilised to the fullest. At the same time sufficient detail is rendered even by tele-photo objectives of small dimensions, as spots and flames often cover enormous areas of the sun's surface. Sun spots have been observed of 300' diameter, or five times larger than Venus in her most favourable position. With a tele-photo objective of 5 m. focus these spots would measure 7 mm.

To recapitulate briefly, the tele-photo objective is only of real use for photographing the moon and sun. For the moon, with the limitation that the advantage of the instrument, long focus in relation to aperture, should not be overstepped; in other words, photographs of the moon, made with a short instrument, should not be too large. Those who undertake observations of these bodies within the limits I have mentioned will find the tele-photo objective very useful, but those who expect pictures such as they are accustomed to see through the telescope will find themselves deceived.

DR. RUD. STEINHEIL.

### A NEW PLATINUM TONING BATH.

PROFESSOR VALENTA has been experimenting with some of the aromatic compounds for toning, and has found that several of the amines are useful. The best proved to be m-phenylenediamine, which has the formula  $C_6H_4 \begin{matrix} \text{NH}_2 (1) \\ \text{NH}_2 (3) \end{matrix}$ , and is formed by the reduction of m-dinitrobenzene with tin and hydrochloric acid.

The hydrochlorate forms small white crystals, which dissolve rapidly in water and give an acid solution.

The salt very quickly reduces solutions of chloride of gold, and cannot therefore be used for the preparation of gold toning baths; but with platinum salts the reduction only takes place after a long time, and then only slightly. The mixture of solutions of m-phenylenediamine and chloro-platinite of potash gives a clear yellow solution which can be used for matt silver paper, and tones quickly and gives excellent results.

The following bath was used:—

Water .....	100 parts.
Chloro-platinite solution (1 : 100) .....	5 to 10 parts.
M-phenylenediamine solution (1 : 100) ...	5 to 10 "

The prints should be washed for a short time in soft water, and then placed in the above bath, in which they assume an intense platinum tone. They should be fixed with ten per cent. hypo, and well washed in running water. The tone of the prints is an intense black with pure whites.

If blue-black tones are wanted, the prints should be first toned for a very short time in

Water.....	1000 parts.
Borax.....	10 "
Sodium acetate (fused) .....	10 "
Chloride of gold .....	5 part.

After this they must be thoroughly well washed, or the gold will be precipitated all over the print.

### FOREIGN NEWS AND NOTES.

**Ammonium Persulphate.**—Dr. E. Vogel writes in the *Photographische Mitteilungen*, recommending this reducer for collodion emulsion negatives. It frequently happens, in copying subjects with much contrast, that the results show the defect of hardness. This is very noticeable in photographing oil paintings with a colour-sensitive emulsion, and, notwithstanding the most careful development, the high lights become over-dense before detail in the shadows is secured. Longer exposure will assist the latter, but the high lights will then suffer from the opposite defect, solarisation. The collodion film is inferior to the gelatine dry plate in this respect, but it has other advantages, such as cheapness and the facility for preparation of plates differing from the ordinary standard sizes. If the ammonium persulphate reducer is used, the negatives may be developed until the shadow detail acquires sufficient strength, quite regardless of the over-density of the high lights. After the plates have been fixed and carefully washed, the reducer should be applied until the contrast is sufficiently lowered to produce an harmonious print. A two per cent. solution is recommended and it is preferable to reduce the negative before allowing it to dry. The negative may be reduced to the full extent desired, as the persulphate is more rapidly removed from the collodion film by washing than is the case with gelatine.

**Over-exposure in Carbon Printing.**—According to Professor Namias an over-exposed carbon print may be rendered amenable to development by previous immersion in a bath consisting of 100 parts of water, 1 part of strongest sulphuric acid, and 5 parts of ammonium persulphate. The print should be immersed, according to circumstances, up to half an hour. The  $\text{Cr}_2\text{O}_3$ , which renders the gelatine insoluble, is converted to chromic acid, and the gelatine is restored to its soluble condition. The picture may then be developed with warm water.

**Decomposition of Fixing Baths.**—The *Photographisches Wochenblatt* draws attention to Dr. P. Michaelis' experiments, an account of which appeared in the *Rundschau* a short time ago. A solution of hyposulphite of soda was prepared of the strength of 1 gramme to 10 c.c. of water. This was exposed to the air in trays,  $13 \times 18$  c., each containing 250 c.c. of the solution. At certain intervals, 10 c.c. of solution were taken from each tray and titrated with a solution of iodine, to determine the quantity of hyposulphite present. Before titration the solution in each tray was poured into a measure, and the water which had evaporated replaced. It was found that the solution deteriorated constantly, but in diminishing degree, as may be seen from the following table:—

Number of days' exposure.	Diminution per cent.	Number of days' exposure.	Diminution per cent.
1	0.74	5	5.2
2	1.98	9	6.2
3	3.72	13	7.44
4	4.46	21	9.92

The loss of hyposulphite would appear to be unimportant, but the deposition of sulphur might seriously affect the image. We may therefore gather from these experiments that it is desirable not to unduly prolong the process of fixation.

**Retouching Pencil.**—The *Photographisches Wochenblatt* also mentions that F. Götz, of Helsingfors, has patented a retouching pencil, the lead of which is kept in rotation during use by means of a small motor. It is claimed that the stroke of the pencil is cleaner and easier.

**The Paper Ring.**—Herr F. Dyck, of Aix-la-Chapelle, has transferred his factory for the manufacture of collodio-chloride paper to Luxemburg. It appears that the ring has omitted to include Luxemburg in its sphere of control, and, as Germany admits Luxemburg manufactures free of duty, Herr Dyck can undersell German competitors by 1s. per quire, or pocket the difference. Probably other German manufacturers may follow his example, and we shall then have an interesting exhibition of the relative strength of patriotism and pecuniary advantage, either on the part of the ring or of the manufacturers.

**Flashlight Accident.**—The *Deutsche Photographen Zeitung* gives a short account of an unfortunate accident which has happened at Berlin in the use of a flashlight mixture. Two photographers, Herren Reiner and Schwarz, were engaged in taking flashlight pictures at a rehearsal, preparatory to the exhibition of a series of living pictures. A violent explosion took place, throwing both photographers to the ground and severely burning their hands and faces. The magnesium powder had been placed on a seat in the middle of the hall, and had been ignited by a cigar end, which had been thoughtlessly thrown away. We gather from another account that the magnesium powder had been mixed with pulverised permanganate of potash. This is one of the safest compounds used for flashlight exposures, and we trust photographers will learn from this unfortunate accident that the greatest care should be exercised when flashlight powders are used, some of them being little less dangerous than gunpowder.

**Photography v. Engraving.**—M. Leon Vidal publishes a sharp criticism, in the *Moniteur de la Photographie*, upon the action of the Paris Municipal Council in voting the sum of 40,000 francs for engraving the pictures at the Hôtel-de-Ville. Several of the principal Paris newspapers have commented upon the subject, and surprise has been expressed that so large a sum should have been

voted, when the work could have been done at far less expense by photography or photogravure. The difference in cost might have been used for the acquisition of other objects of interest. To those who reply that the art of engraving should be encouraged, there is the obvious retort that many other arts contributed to the artistic pleasures of our forefathers, and, if all received due encouragement, the Municipal Council might spend the entire wealth of the city without fulfilling its duty. M. Vidal justly observes that, if a correct reproduction of these works of art is desired, orthochromatic photography is available, and is not only less expensive, but more truthful, than any process of the engraver. As proof of this fact, we may take the interpretation of any one picture by various engravers and compare them. They not only differ among themselves, but they all differ from the original. We may respect the patience, ability, and artistic feeling of the engraver, but it is regrettable that photography should not be used when a facsimile is wanted.

**Nitric Acid in the Pyro Developer.**—In preparing a stock solution of pyrogallie acid with sulphite of soda the addition of a few drops of nitric acid is frequently recommended. The *Photographische Mitteilungen* points out that nitric acid is an undesirable addition, as it is an oxidiser, and tends to reduce the strength of the developer. It is preferable to use sulphuric acid to neutralise the alkalinity of the sulphite of soda.

**Photographic Plates v. the Eye.**—Professor J. Scheiner writes in the *Archiv für Wissenschaftliche Photographie* concerning the application of photographic methods to the exact sciences, and especially to astronomy. In making a comparison between the eye and the dry plate, Professor Scheiner points out that it is the accumulation of the effect of light which gives the plate the advantage. If we look through a telescope of three inches' aperture, and the eye is not fatigued, stars down to the twelfth magnitude may be distinguished, and for this purpose the observation need not exceed ten to twenty seconds. A plate exposed for the same time under similar conditions would only record stars down to the sixth magnitude, and we might infer that the eye is 250 times more sensitive than the plate. From experience we know that an exposure of an hour has to be given to a dry plate with the same telescope, if we wish to obtain a record of the stars we can distinguish with the eye. If we give still longer exposures, the advantage lies with the plate; and, as astronomical exposures have been made of twenty-five hours' duration, it will be readily understood how great is the service photography renders to the astronomer.

#### LEEDS CAMERA CLUB.

##### WITHDRAWAL FROM THE YORKSHIRE PHOTOGRAPHIC UNION SCHEME AND THE AFFILIATION.

At the usual weekly meeting of the above Club, on Wednesday evening, February 8, the President (Mr. W. J. Warren) mentioned that there were two resolutions to be dealt with before he called upon Mr. Burrill to give his lecture on "Photographic Chemicals."

The first and most important item was the question of the Yorkshire Union. As they would, no doubt, have seen from the photographic papers, a meeting was held on Jan. 27 at Bradford, some of their members were present, and representatives also attended from some fourteen or fifteen Societies in Yorkshire, when a resolution was passed "that it was desirable to form a Union of Yorkshire Photographic Societies." Mr. Percy Lund was in the chair, and Mr. Ezra Clough, one of the Secretaries of the Yorkshire Exhibition, explained that the draft scheme had been prepared by some eight members of the Bradford Photographic Society.

The President then shortly read to the meeting the main heads of the proposed scheme, which has already appeared in our columns. Proceeding, Mr. Warren remarked that the interchange of lectures was probably the most important feature. First of all, a list would be made out of gentlemen in the county who would be willing to give three, six, or nine lectures. These would form a joint batch of lecturers, and of these every society would have two, and every society would also have one lecture in addition for every lecture which it gave to the common pool. There was also to be kept a lecturing staff, and prominent men in different parts of the country, who would receive a certain fixed fee, and pay a percentage of such fee to the Union. Those were roughly the heads. He was bound to say that at the meeting, at which the Leeds Camera Club were represented by Messrs. Bourke, Gash, Silcock, Rust, and himself, there was a considerable amount of reticence when the resolution was proposed, and probably perhaps not more than one-third of the gentlemen present voted. The others seemed to be waiting for

something to turn up. However, the Committee had considered this question very carefully last night, and he did not think there was any difference of opinion on the Committee with reference to the Union, and, after careful consideration, they had voted for a certain resolution, which he would read as follows—"That, in the opinion of the Committee, it is not desirable that the Leeds Camera Club should join the proposed Yorkshire Union." It was not necessary that the Committee should come to the members with regard to the matter, but at the same time it was very reasonable that they should do so, and ask them to decide this question. The Committee had said that, in their opinion, union was not desirable, and he hoped the members would look at it in the same way as the Committee had done, and confirm the resolution. The opinion of the Committee was that they had to look at it selfishly. The Club was not a charitable institution to give lectures to some societies; they had to run for their own benefit, and the Committee were of opinion that there were no benefits to be obtained from the Yorkshire Union to the Leeds Camera Club. They had compared the probable syllabus which would occur if they were members of the Union, and, even if they got the best men of the country giving lectures in exchange, they would gain very little by the bargain, and the syllabus for 1899 would be no better than the one for 1898. They also looked at it from another point of view, and he thought a reasonable one. They said we have seen the experience of other attempts at federation, and these have led us to believe that whenever you attempt to unite conflicting atoms you have got a very thick thing on. Now, every society in Yorkshire is a conflicting atom, and every society of the Union would be conflicting atoms. We judge from the gentlemen who promoted the scheme, and from the Chairman and Secretary, that it looked as if the first conflicting atom should be met in order that the thing should be equalised. There were twelve conflicting Bradford atoms to be dealt with. It was all Bradford, and, instead of being united to the whole societies of Yorkshire, at present the proposal seemed as if there were to be united to eleven Bradford gentlemen. If they were going to have any fighting to do or hard work, the opinion of the Committee was they had better do it for their own Club than a Yorkshire Union. Whatever energies they could put forward were infinitely better put forward for their own Club exclusively. It was perhaps a selfish way of looking at it, but the Committee had a duty to perform to their members, and that was to work as hard as ever they could for their own Club, and not waste their energies on outside matters. That was the reason why he proposed this resolution, and he thought he might say it was, to a certain extent, the reason the gentlemen of the Committee voted for it.

Mr. Warren then formally moved the following resolution—"That, in the opinion of the Leeds Camera Club, it is not desirable that the Club should join the proposed Yorkshire Union," which Mr. Elliff seconded, and, on being submitted to the meeting, was carried unanimously.

Mr. R. Bourke then rose to propose resolution No. 2 as follows—"That, in the opinion of this Committee, and while agreeing with Mr. Harold Baker in wishing to see the Royal Photographic Society take its proposed place as the leading society of the country, which at present it does not do, especially with regard to its exhibitions, the Leeds Camera Club severs its connexion with the Affiliation Committee of the Royal Photographic Society as at present constituted." In placing the proposition before the meeting, he said that it would require no words from him to commend the resolution to their approval after the vote they had just taken. It was his opinion now, and the opinion of the Committee, that the time had come when the Leeds Camera Club could fairly stand apart from combinations, and therefore he had submitted the resolution now before them at the meeting of the Committee last night, when it was carried unanimously.

The resolution, having been seconded, was then put to the meeting and carried.

#### THE UNION OF YORKSHIRE PHOTOGRAPHIC SOCIETIES.

The adjourned meeting in connexion with the movement for forming a Union of Photographic Societies was held on the 9th inst., at the Bradford Grammar School. Mr. Percy Lund again occupied the chair, and there was a large attendance.

It transpired that the number of the members of the societies who were favouring the scheme was as follows: Brighouse, 87; Batley, 40; Beverley, 50 (estimated); Bradford, 200; Hull, 156; Heckmondwike, 80; Keighley, 64; Leeds, 150; Sheffield, 46; Rodley, 12; Wakefield, 12.

Mr. Clough said, as to Halifax, he knew that a member of their Committee had stated his Club were in favour of the scheme, but there had been no opportunity of bringing it before the Committee. As to Huddersfield, it would not be fair for him to say. He was most anxious not to commit any one, but, so far as he knew, they were in favour. He was placed in an unfortunate position. There were certain letters in his possession from secretaries who were in favour, but he was not prepared, as a matter of diplomacy, to commit a society until he had received their final answer, when he would read it, but the opinion of a secretary he was not prepared to take. Leeds was the only opposition, with the ex-

ception of Rotherham Society, last week, who had rejected the scheme unheard.

The Chairman stated that the circular should have asked for an expression of opinion from outside societies who were unable to be represented that night, and who were not likely to come to the meetings, this was the first thing to be done; there were still practically twenty societies in Yorkshire from whom they had heard nothing at all.

The consideration of the proposed constitution was then proceeded with. It was resolved that the Union consist of a President, three Vice-Presidents, Recording Secretary, paid Secretary, Treasurer, Committee, Delegates, and Associates.

Mr. Bourke was of opinion that every encouragement should be given to Associates to join.

The Chairman: We want to prevent the larger societies dominating the smaller societies.

Mr. Bourke: Could not it be arranged that there could be some representation on the Committee?

The Chairman: How are Associates to elect themselves? He went on to explain, that supposing the Union engaged a lecturer from, say London, for a series of lectures, he would take less in proportion for such an engagement than if he had but a single engagement. This would be a source of economy to the societies.

Mr. Georgeson: Surely it was never understood we could get lecturers for this nominal sum.

Mr. Ezra Clough thought it would be an advantage to get Mr. Harold Baker to deliver a series of lectures.

Mr. Georgeson: It would be better to get Mr. Baker for the lectures, and our subscriptions to remain at 15s.

The Chairman remarked that what was before the meeting was the following: "Societies can enjoy the privilege of the Union on the following terms: Those having a membership roll of fifty or less, 10s. per annum; 15s. for those having a hundred, or less; and 20s. for all above that number. These societies shall be allowed to send to the elective body one, two, and three delegates, respectively, according to the fee; no Society, whatever may be its membership, shall be allowed more than three delegates.

The Hon. Secretary said the advantage of the Union would be that it would be able to do something better for the societies than they could do for themselves.

Mr. Sheard suggested that six was a reasonable number of delegates to appoint, and the Chairman agreed with this.

Mr. Sheard thought the delegates should have the power to elect six Associates on the Committee of twenty-five.

After some further discussion, the Chairman announced that the Committee would be increased plus the Associate portion of the Committee.

It was also decided on the following: "All members of societies who had joined the Union became Associates, and are entitled to attend the Annual Excursion, the General Meeting, and any Union lecture, wherever they may be given. Any person may join the Union as Associate by paying a subscription of 2s. 6d. per annum. Prior to this, however, a lengthy conversational discussion took place as to whether the Associate should not pay 5s. instead of 2s. 6d.

The Chairman thought they did not desire that societies who had done nothing in the movement should send individuals so as to upset the balance of power. They would remember at the last meeting they decided on 2s. 6d. in preference to 5s.

Mr. Bingley said in another society any member could become an Associate on payment of 5s.

The Chairman pointed out that there had been nothing decided as to Associates having voting power.

They would see it was not final. Delegates would have this to work upon, and it was only a minor point. It was no use having the whole thing printed again. Delegates would have formed their opinion at the right time.

It was resolved to defer the question of appointing a paid Secretary.

The following was also agreed upon:—

"The Elective Body: These delegates shall form the elective body of the Union. This body shall elect the officers and Committee, the numbers to consist of not less than twenty-five, to form the Committee and officers, which shall have power to transact all business of the Union. The Committee and officers shall be nominated a month prior to the General Meeting, and elected by voting papers sent to every delegate by post, to be returned five clear days prior to the General Meeting. This Committee shall elect the officers of the Union. The Committee and officers shall retire annually, but be eligible for re-election. The delegates shall elect the number of Associates to act on the Committee. All who vote must have paid their subscriptions."

Mr. Sheard thought it would be well to have only half the officers retire.

The subject of a 10s. subscription was again introduced.

Mr. Heape spoke in favour of it, and

The Chairman said he was against any increase at present. They did not yet know what they might develop into—the scheme was as yet only on paper.

Mr. Ormerod: I propose we haven't a minimum subscription of 10s. 6d. from each society, but pay 3d. a head.

The Chairman: This matter was considered at the last meeting. It was decided it must remain the same.

Mr. G. Bingley: I am afraid if it is put to 30s., very few societies will have anything to do with it.

Mr. Georgeson: I propose that the subscription stands at the present figure until we have a delegate elected from each club.

The Chairman then took the feeling of the meeting, and declared that it was in favour of the original suggestion.

A gentleman who was present intimated that he would bring the matter forward at the next meeting.

On the motion of Mr. Sheard, seconded by Mr. Georgeson, and supported by Mr. Bourke, it was decided that the previous recommendation should be passed, though there appeared to be some difference of opinion on the question of secretary.

The "Probable Facilities of the Union" (which have already appeared in these columns) were then formally gone through and agreed to.

A suggestion was made by Mr. Briggs (Wakefield) to hold the meetings of the Union monthly.

Mr. Ormerod moved as an amendment that the meetings be fortnightly.

On a vote being taken, thirteen votes were recorded for the amendment and five against.

The amendment was declared carried.

The next question to be considered was the night of meeting.

A proposition was made that the next meeting should be held at Bradford on March 1.

Mr. Ezra Clough intimated that it was utterly impossible, owing to a previous engagement, he could attend on that date, and after some discussion it was decided to fix the meeting for Thursday, March 2.

The Chairman pointed out that it would be advisable for the members of the Union to decide on some description of a distinctive badge, to be available for any one connected with it.

It was resolved that this matter be left over for consideration.

The Chairman said it appeared to be somewhat doubtful, in the hurry and confusion of closing the previous meeting, as to whether it had actually been decided to form the Union. Possibly the fault lay with him, but he would call upon Mr. Ormerod to move that the Union be formed.

Mr. Ormerod proposed the motion, which was seconded by Mr. Heaps and carried.

## THE L. AND P. SUPPER.

BY A GUEST.

"A joint of mutton and any little kickshaws, tell William, cook."—*Shakespeare*.

"By your gracious patience I will a round and unvarnished tale deliver."—*Ibid*.

Our photo motor car stopped at the witching hour of 7.35 at the sign of the Ancient Cygnet, a hostel close to the precincts of that temple whereof the lamb and flag are a fitting sign manual.

The foggy, groggy gloom of printer's paradise was enlivened by the majestic roll of well-filled growlers pulling up in rapid succession at the door and discharging their loads of photographic citizens on pleasure bent, for was it not the auspicious occasion of the L. and P. supper and social after a lapse of fifteen years? Rival and ragged touts waylaid the unwary fare as he alighted, in the hope of obtaining the much-prized end of cigar or cigarette, that even the blind beggar cannot resist when he smells its fragrant odour wasting its sweetness on the desert air in the neighbouring gutter—his instinct never errs, and he gauges its position and grabs the smouldering stump with the accuracy of an American gunner.

My friend and I were late and the company was seated, but we were received by a cordial gentleman, resplendent in a velvet coat, and smiles, who wanted to part us till after dinner, but we were obdurate, and got a seat together at the end of a table in spite of mild rebuke; and it was well for me, for, had my friend left me, it would have been some hours before we should have met again.

From the vantage point assigned to me, I gazed around with admiring glances at a goodly gathering, and I hope I may be pardoned for following in the footsteps of one of your recent contributors by perpetrating another parody on *Inglisby*:—

The president sat in an easy chair;  
Artist, and servant, and others were there;  
Two or three eds., and a writer or two,  
Three colour men, and amateurs, who,  
With a great many more, of even degree,  
Made quite a goodly company.  
And they smiled at each other cordially.  
Never, I swear, was a meeting where,  
Whether in town or country or not,  
The air was so frightfully stuffy and hot."

Yes, it was extremely hot, and fresh air was decidedly at a premium; but then a madman suddenly opened a window quite close to me, and had it not been for the long hair of my neighbour, which kept the draught

away from me, I should now be spending my week's end in bed. But I am digressing, and must continue my parody:—

"In and out through this social rout  
Four little waiters kept popping about.  
Here and there, like dogs in a fair,  
Touching coat-sleeves and pates with dishes and plates.  
Jim and John and Joey, we howl,  
Bring the potatoes and give us some fowl.  
With saucy air Joe approaches the chair  
(After the lapse of an hour or two),  
Saying mutton and beef's all they can do;  
And we sighed in his face and thought of the place  
Where the cooking is good and the prices right  
(Nor have you to wait for it half the night).  
Our friends, too, were raw, like the beef they saw,  
And they wanted a punch at the caterer's jaw."

Yes, Mr. Editor, it is just as well that there were "no men of unbounded stomach" present, and that the great Sala is at rest, for, had he been at the feast, his pen would have dried up in the agony of suspense caused by the ignorance of some of the waiters and the fearful delay between the courses.

I once heard a tale of an ignorant old lady who was on a visit to town for the first time, and whose friends decided to take her to the theatre, and showed her a programme beforehand. As the hour approached for this lady to depart, her friend who was to go with her noticed that there was a rather large box in the hall, and she naturally asked what that was for.

"What for?" reiterated the old lady. "Why, to take with us, of course."

"But what do you want a large box with you for? They won't let you take it in."

"Not take it in?" she replied. "Why, it's full of food. There's to be an interval of two days between the first and second acts."

Now, some of us felt like that at this supper—we wished we had brought our own food, for we literally got nothing to eat, and were a tremendous time in not eating it. Two gentlemen not unknown in the photographic press waited twenty-five minutes between one course, fifteen minutes another, and over twenty minutes before they could get a drink. I speak with authority, as my own Waterbury timed it.

The waiter at our table was a shock-headed youth—almost in his chrysalis state—to whom we said, "Champagne list" as plainly as we could. Well, he just opened his eyes so wide I thought he'd never get 'em back again into his head. He disappeared for fifteen minutes. Again we reiterated "Champagne list." He shook his shaggy mane and then brought an antiquated, dirty, thumb-marked card. We said, "A bottle of Bollinger." Again the dead-codfish look came into the creature's eyes; his mind could not grasp the magic word, and we sent at last in despair for the head waiter, and got, after another long interval, the coveted beverage.

Some one remarked that this was a "beef and beer horror," and so it was, but worse was to follow. An excellent programme of vocal and instrumental music and other et-ceteras had been arranged, and a genial gentleman, rejoicing in a compound patronymic, and hailing from the gallant little land of Wales, sat down to the piano.

He played one minute amid a torrent of hisses, not at the pianist, for he is a most accomplished musician, but at the quality of the instrument.

Does not some one say in the *Merchant of Venice*, "The vile squeaking of the wry-neck'd fife?" That is a mild expression as compared with those lavished by the whole company on that ancient and beer-stained jumble of jangling strings erroneously called by the manager the piano, and, try as they would, the wretched thing spoilt the pleasure both of the performers and audience.

The speeches savoured somewhat of the mutual admiration society sort, each speaker vying with his predecessor in the amiable art of flattering his neighbours, and, although the two-minute rule was strictly enforced, expressions of congratulation on the success of the Society and its past and present members were freely heard and duly appreciated, and we broke up at a reasonable hour, only regretting the dreadful dinner and the horrible piano; and, if the Society holds another "supper," let us trust it will be at one of the large West-end restaurants, where, for the same fee (3s.), a far better menu can be had with suitable attention and an instrument that is worthy of its name.

## CHEMICALS USED IN PHOTOGRAPHY.

BEFORE the Leeds Camera Club, on Wednesday, February 9, "Chemicals used in Photography" was the subject for consideration, and it was dealt with by Mr. B. A. Burrill, F.I.C., of the Leeds Photographic Society. Every photographer, said Mr. Burrill, should, in order to do good work, know something of the materials he is using. The science of chemistry laid down certain laws and principles which must be adhered to, or photography would be impossible. An elementary knowledge of those principles was, therefore, not only advisable, but necessary. Chemists divided all substances into two classes, elementary

and compound, which united with each other in certain definite forms. Their atoms had a numerical value and weight, and they combined in the exact proportions of these atomic values, any excess of either remaining uncombined. Applying, then, these principles to the development of the photographic plate, the solutions used were divided into certain groups. First there was the reducer, such as pyro, metol, or any of the others, which reduced to the metallic state the silver salts acted upon by the light; another was the accelerator, such as ammonia, alkali, or carbonates, which were necessary to start the action of the reducer. Then there was the restrainer, such as the bromides, which prevented the too violent action of the reducer. Then came the water, which was the solvent and diluent; and after that the sulphite, to prevent staining. The absolute necessity of using pure water was demonstrated by Mr. Burrill showing the action of impurities in well and tap water in contrast with distilled water, and he showed how an operator could when in any district away from home test the water, and, having found its principal impurity, counteract its effect by precipitation of its objectionable features. Dealing with the accelerators, the lecturer advised all who used ammonia to get it of full strength, and at once dilute it to a ten per cent. solution, otherwise its gases, being so very light, were escaping every time the bottle was uncorked, so that they never had a standard strength of solution. The potash and soda hydrates were explained, and their essential features demonstrated by experiment. In the carbonates the lecturer clearly showed the difference between the ordinary washing soda and the pure soda carbonate, the washing soda containing thirty-seven per cent. of carbonate, the rest being water, so that, in mixing their solutions, they must use the exact weights and substance as given by the maker's formula. Soda carbonate is the best for pyro, but for metol and developers of that class the potash carb. is to be preferred. The action of the restrainers was then demonstrated, Mr. Burrill showing how an unrestrained developer must produce a slight deposit of metallic silver over the whole surface of the plate. He advised the operator always to use potash bromide with carbonates, for ammonium bromide would cause decomposition, giving off ammonia gas, and so altering the character of the developer. As to sulphite, he pointed out that it was absolutely necessary for this to be kept from the air, or sulphate was formed, which was most detrimental, and the cause of many of the ready mixed developers, sent out by the makers, giving such poor results, was largely due to this factor. Its preservative qualities, when used with pyro, were explained, a little citric or sulphuric acid being added to give an acid reaction. Mr. Burrill strongly advised operators never to use a combined hardening and fixing bath, and he demonstrated by experiment the actual results of so doing. If they used the alum bath, wash thoroughly after developing, and again before they put it in the hypo bath. The hypo or fixing bath at once removed all the unaltered silver from the plate, and the lecturer explained and demonstrated its chemical action. For those who preferred an acid fixing bath, he advised them to use soda metabisulphite 1 ounce, hypo 4 ounces, and water 20 ounces. The hypo bath was best made up a day or two before, and then decanted off, some slight deposit generally being formed. The best eliminator was water, and plenty of it; but a solution of 2 parts of Condy's fluid (permanganate of potash), diluted to 100 parts with water, could be used, adding more of this solution until the pink colour remained permanent, and then no hypo would be present.

## Our Editorial Table.

### A WORD ABOUT WELLINGTON PAPERS.

Published by Wellington & Ward, Elstree.

Like everything that comes out of Elstree, this little book is distinguished by style and good taste. To the users of the Wellington papers the explanatory notes and instructions given will be of immense service in the manipulations of those papers. As showing what good prints are obtainable on them, there are four charming bromides on varied surfaces bound up in the book, the negatives having been taken by Mr. Wellington and Mr. Ward. *A Word about Wellington Papers*, with the four pictures, is sent free to applicants.

### THE DIAMOND RETOUCHING VARNISH.

Manufactured by C. Brangwin Barnes, 21, Alloa-road, Deptford-park, S.E.

This new retouching varnish, which Mr. C. Brangwin Barnes, an experienced photographer, is issuing, gives a surface as easy to work upon as paper.

Being practically colourless, it does not interfere in any way with the printing qualities of the most delicate negative, does not become tacky in the hottest weather, and does not decorticate under the influence of fog or damp. It is hard and unscratchable, and can be retouched upon, and printed from, while the negative is still warm. A sample negative, coated with the Diamond Varnish, afforded us the opportunity of testing and verifying the claim made in its behalf.

### THE "KALKO" BACKGROUND PAINT.

Manufactured by the Vanguard Manufacturing Co., Maidenhead.

MANY a photographer will welcome the opportunity of purchasing a shilling tin of this material which, when converted by hot water to the consistence of thick paste, can be used for painting upon a variety of surfaces that are useful for photographic backgrounds, such as paper, cheesecloth, canvas, wood, and stone. The manufacturers point out that a few stout newspapers (such as the *Times*) glued together at the edges and coated with "Kalko" paint make an excellent background or lantern screen. "Kalko" is made in four tints: dark slate grey, medium brown grey, cream, and snow white. The contents of a package will give two coats to an average-sized background. One coat is, however, generally sufficient. The directions for use are: Put the contents of a package into a basin, or other suitable vessel, and add one pint of hot water. Only a little of the water should be added at first, and the mixture should be stirred well until it forms a thick smooth paste. The rest of the water may then be slowly added with constant stirring until the paint is quite smooth and creamy. It is then ready for use, but works better when cold. Apply smoothly with a large brush. The work need not be sized, or prepared in any way. No studio should be without a supply of "Kalko" background paint.

### GRAVURA.

Manufactured by the Paget Prize Plate Co., Watford.

LAST week we referred to the receipt of a number of specimen prints on Gravura, the new gaslight development paper of the Paget Company; and, from the fact that the range, richness, and beauty of the colours of these pictures, which are obtainable by exposure and development alone, have been much admired by those who had seen the prints at our office, it is fair to suppose that, in placing a paper of this kind on the market, the Paget Company has happily hit popular taste in the matter, and that Gravura will be exceedingly popular with those who like a development paper giving colours ranging from black to bright red. We have tried the paper with satisfactory results—it is not inconveniently slow, that is, with a negative of average density it requires for black colours an exposure of about two minutes a few inches from a gas flame, and thus it is handled and developed without fear of fog in a room well illuminated by gas. We append the chief instructions for the principal manipulations, by which it will be seen that by modifying the exposure and development factors, if we may so term them, command is easily obtained over the colours of the images.

The packets may be opened and printing frames filled in an ordinary gas-lighted room—say not nearer than six feet from the flame, or in daylight, in a room with the blind drawn down and not too close to the window. Development may be carried on under the same conditions.

The exposure required for black tones by contact printing under a negative of medium density will probably be from one to two minutes at, say, four inches from an ordinary gas flame, or from one second upward in diffused daylight inside a room a few feet away from the window, or half an inch to an inch of magnesium wire burnt at a distance of twelve to eighteen inches:—

#### Developer.

Hydroquinone .....	1 ounce or 55 grains or 6 grammes.
Metol.....	1 " " 14 " " 1.5 "
Sod. sulphite recryst....	8 ozs. " 1 ounce " 48 "
Sod. carb. crystals .....	10 " " 1 1/2 " " 60 "
Pot. bromide .....	16 grains " 2 grains " 25 "
Water to make.....	1 gallon " 1 pint " 1 litre.

For black tones only the paper, after exposure, may be wetted for a few seconds in order to make it limp and lie flat. It may then be either developed in a clean dish, by pouring the developer over, or laid on a sheet of glass and the developer rapidly painted over its surface with a brush or tuft of cotton-wool. In either case the developer must be spread quickly and evenly and without bubbles: we prefer the dish. Development for black tones takes place very quickly, and will probably be completed in from fifteen to thirty seconds. As soon as the required stage is reached take the print out at once, dip quickly in water, and immerse in fixing bath, keeping it moving in this bath for the first few seconds:—

Hypo. ....	3 ozs.
Water .....	1 pint.

Fix for about ten minutes and use fresh solution for each batch of prints. Wash thoroughly in running water for about an hour (not longer), or in several changes. Do not expose to strong light until thoroughly fixed.

If an exposure, say, five or six times as long as required for black tones be given, and a diluted and restrained developer be employed, it will be found that the image will take much longer—perhaps one or two minutes—to come out, and when it first appears will be of a yellow or pale pink colour. As development progresses this colour will gradually change, the red becoming stronger and deeper, changing to a brown red

then through successive shades of brown to olive green. [This description applies to the appearances as seen by gaslight or other yellow light.] Now if the print be taken out at any stage of this process, fixed and finished, it will be found, when dry, to be of nearly the same colour as when taken out of the developer, except that it will have gone back a little towards orange and will appear stronger. It will depend upon the exposure whether the correct stage of development as regards detail and strength of image had been reached when the desired colour had been arrived at. For example, suppose that a red print had been desired, but that, when the red stage had been reached, the image was not sufficiently developed out, and that therefore you had to go on longer. You would get a sufficiently developed image, but the brown or brown-red stage would have been arrived at and a print of corresponding colour would result. In order to get a red print you would have to expose longer, so that the image had developed sufficiently by the time the red stage had been reached. On the other hand, if the exposure had been too long the requisite detail would have appeared before the red was deep enough; and, if taken out, the print when finished would be yellow or orange; if left in until red, it would, when finished, be too flat and over-printed.

Calling black the bottom of the scale, and pale yellow the top, the higher the colour desired the longer the exposure, and the more diluted and restrained the developer must be.

#### LA PHOTOGRAPHIE ANIMÉE.

By EUG. TRUTAT. With a Preface by J. Marey. Paris: Gauthier-Villars et Fils, Rue des Grandes Augustins.

Those who are interested in the subject of animated photography will find this book a useful addition to the library shelves. M. Marey, the famous chrono-photographer of the movements of animals, &c., contributes a preface to the volume which, in return, draws largely upon Marey's own work, *Mouvement*, for the matter of some of its earlier chapters in which the familiar references to persistence of vision, and the various forms of the zoetrope are dealt with. The growth and development of the modern cinematograph is then traced down through the work of Muybridge, Edison, Anschütz, and others, and the greater part of the volume is taken up with descriptions of French apparatus and the manipulations necessitated in the production of animated photographs. The author appears to be unfamiliar with the fact that English inventors have had something to do with animated photography; but, notwithstanding this defect, the book is a very useful one. It has many illustrations and is priced five francs.

#### CATALOGUES RECEIVED.

Henry M. Ward, 41, Belgrave-avenue, Leicester.

MR. WARD, who works for the trade, has sent us his latest list. His specialties are sepia and warm-toned enlargements in bromide, and finishing in monochrome and water colours. Specimens of his "Auro" enlargements in rich, warm browns, which he submitted to us, confirm us in the opinion we originally expressed of them, namely, that they are attractive and effective, and should command the patronage of photographers, now that the public shows unmistakable signs of taking to warm-toned photographs.

#### THE ELGE COLLECTION OF CINEMATOGRAPH FILMS.

L. Gaumont & Co., 25, Cecil-court, Charing Cross-road, W.C.

We recommend this catalogue to those who contemplate organizing entertainments in which animated photography is designed to play a part. Nearly 200 subjects are listed, and to each film a brief and pointed description is devoted. Most of the more attractive themes are illustrated, so that an idea of their nature is directly obtainable. The three or four nudes seem calculated not to offend against the canons of good taste or propriety. We note that the Life of Christ has supplied inspiration for the preparation of one series of films. Opinions will always, we may suppose, be divided as to the wisdom or expediency of subjecting the sacred writings to contribution for purposes of photographic illustration. Our own opinion is that they are best left alone. Nothing is lost by such a course of reverential reticence; and, moreover, by not showing them, there is the certainty that the risk of giving offence has not been run. We hope these remarks will be taken in the spirit that animates them, viz., a desire to save photography the reproach of being improperly used.

Wilfred Emery, 3, Soho-street, W.

MR. EMERY'S latest catalogue of 22 pages, contains mention of the "Apek" specialties: hand-cameras, studio cameras, shutters, &c., and prices for developing, printing, and enlarging are also given. Photographic materials of a miscellaneous character make up the remainder of this illustrated price-list, which is sent free to applicants.

## News and Notes.

**SOUTH LONDON EXHIBITION.**—Entries for this Exhibition close on February 18. Photographs must be delivered by the 25th.

**PHOTOGRAPHIC CLUB.**—February 22. Travellers' Night. "Cumberland Fells and Lead Mining." Slides by Mr. W. D. Welford.

**ROYAL PHOTOGRAPHIC SOCIETY.**—Tuesday evening, February 21, at 12, Hanover-square, at eight p.m., "Demonstration with Violet Electric Waves for Actuating Photographic Apparatus and for Photographing Lightning in Daylight," by F. H. Glew.

**J. H. DALLMEYER, LIMITED.**—We are informed that this Company last week declared and paid a dividend at the rate of eight per cent., making with the interim distribution a total of twelve per cent. for the year. We congratulate the Company on its prosperity and progress.

**SOUTHAMPTON CAMERA CLUB** (established 1896).—This Club's meetings are held at the Kell Memorial Hall, Bellevue-road, Southampton, on alternate Monday evenings. The officers are:—*President*: Rev. G. C. Bennett.—*Committee*: Messrs. Jarvis, Evens, Winzar, Stone, and Walter.—*Hon. Treasurer*: Mr. W. H. Trigg.—*Hon. Secretary*: S. G. Kimber, Oakdene, Highfield, Southampton.

At the South-Western Polytechnic, Chelsea, last Saturday, Lady Amptill distributed the prizes and certificates. In the Photographic Section the following awards were made:—Mr. Arthur Lockett, 1st prize, honours grade, 2/ (Salters' Company), silver medal and certificate (City and Guilds); Mr. Walter Atchison, 1st prize ordinary grade, 1/ (Salters' Company), silver medal and certificate (City and Guilds).

**THE SANDELL FILMS AND PLATES, LIMITED.**—Mr. J. T. Sandell writes us as follows: "I beg to inform you that by the help of a powerful Syndicate I have succeeded in reconstructing my Company, lately known as the Sandell Works Company, Limited. In future the new Company will be known as Sandell Films and Plates, Limited. The address will be as heretofore, namely, Selhurst-road, Norwood Junction, S.E. The business will be under my management."

In a recent number of the *Journal für Gasbeleuchtung* M. Drossbach has an interesting note on the theory of incandescent gas-lighting. According to the author, the light given by an Auer mantle is due to the influence exercised by the molecule of oxide of cerium. This influence consists in bringing the calorific vibrations of the thorina into harmony with the calorific waves of the flame, which are then transformed into luminous waves. The author has prepared nitrates of thorium and cerium as pure as possible, and he found that the maximum illuminating power was given by a mantle containing 99.1 per cent. of oxide of thorium, and 0.9 per cent. of oxide of cerium. The substitution of zirconium for thorium gives bad results. He concludes that oxide of cerium does not possess any chemical or catalytic action. It has been stated that thorina prepared from the nitrate is always very voluminous, and that the great surface it offers to the flame favours the catalytic action of the oxide of cerium. Now the author shows that the sulphate, which makes a compact oxide, gives as good results as the nitrate.

**SOLUBILITY OF CERTAIN SULPHIDES IN GLASS.**—It is known that sulphides of the heavy metals, and especially cadmium sulphide, are dissolved unaltered by melted glass, which enables one to obtain a number of colouring substances for glass. In the production of glass coloured with cadmium sulphide, certain difficulties had formerly to be surmounted; to-day, fancy glass, coloured with cadmium sulphide, under the denomination of "Kaisergelb," is manufactured on a large scale, which is distinguished from the brownish-yellow silver glass by its brilliant deep-yellow colour, with a faint tinge of green. As regards the solubility of other sulphides, we would mention the following mixtures: A. Sand, 65 decigrammes; potash, 15 decigrammes; soda, 5 decigrammes; lime, 9 decigrammes; molybdenum glance, 3 decigrammes; sodium sulphide, 2 decigrammes. From this results a handsome, dark red-brown, ruby colour. In thin layers the glass appears light brown-yellow; flashed on opal, it turns a dirty black-brown, which appearance is, by the way, also observed with other sulphides, and may be traced back to the fact that the sulphide precipitates from the rather concentrated solution on repeated heating. B. Sand, 50 decigrammes; potash, 15 decigrammes; soda, 5 decigrammes; lime, 9 decigrammes; molybdenum glance, 1 decigramme; sodium sulphide, 2 decigrammes. This gives a yellow which strongly tarnishes glass. C. Sand, 10 parts; potash, 3.8 parts; soda, 0.27 part; lime, 1.64 parts; molybdenum glance, 0.03 part. This gives a reddish-yellow glass with a very handsome tinge of red. D. Sand, 100 parts; potash, 26 parts; soda, 1.8 parts; lime, 12 parts; cupric sulphide, 1.7 parts; sodium sulphide, 1.8 part. This yields a sepia to sienna coloured glass, dark brown, no longer transparent in a tolerably thick layer, but clear and undimmed. By heating, it turns dirty dark brown and dim; thinned with cutting glass and flashed on opal, agreeably warm sepia shades are produced which, obtainable in any desired intensity resemble the natural paper of the painters, and are especially suited as a background for designs or glass painting. Experience has shown, however, that glass coloured with sulphides is not so easy of production as that coloured with silicates. This is for the most part owing to the nature of the sulphides, to their ready oxidizability, their comparatively greater volatility, and to the fact that metallic sulphides are entirely different from the substance of glass, and cannot therefore be melted together with it in any desired quantity.—*Diamant*.

## Patent News.

THE following applications for Patents were made between January 30 and February 4, 1899:—

MAGAZINE CAMERA.—No. 2189. "Photographic Magazine Camera." Communicated by H. D. Haight and L. L. Cossitt. Complete specification. R. E. PHILLIPS.

ANIMATED PHOTOGRAPHY.—No. 2372. "Improvements in Apparatus for Photographing Moving Objects upon a Strip of Moving Transparent Film, and Projecting Pictures so taken." A. V. MORTLEY.

ANIMATED PHOTOGRAPHY.—No. 2376. "Improvements in Apparatus for Displaying 'Living' Pictures." A. B. LANGHAM.

PLATE AND FILM CHANGING.—No. 2457. "Improvements in or relating to Mechanism for Changing Photographic Plates or Films." C. J. BANNISTER.

DISHES.—No. 2473. "Improvements in or relating to Dishes used for Developing or other Operations in Photography." Complete specification. J. ROBINS.

ANIMATED PHOTOGRAPHY.—No. 2575. "Improvements in Apparatus for Taking, Projecting, or Inspecting Series of Photographs." W. BRITAIN.

ANIMATED PHOTOGRAPHY.—No. 2582. "Improvements connected with Apparatus for Displaying Photographs and Transparencies, generally Cinematographically, with Coin-freed Appliances." W. S. SIMPSON.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

February.	Name of Society.	Subject.
20	Barnet and District .....	Lantern Night.
20	Birmingham Photo. Society ..	Last Day for receiving Entries for Annual Exhibition.
20	Bradford Photo. Society .....	Trade Demonstration. A. C. Baldwin.
20	Camera Club .....	Glaciers and Fjords in Bergen District, Norway. Horace W. Monckton, M.A.
20	Darwen .....	Prize Slides.
20	Kingston-on-Thames .....	Rome and Naples. A. Vandendriesche.
20	Richmond .....	Demonstration of Velox Paper. John J. Griffin & Sons, Limited.
20	South London .....	The Rotterdam Excursion, 1898. By those who went.
21	Birmingham Photo. Society ..	Social Evening.
21	Bootle .....	Demonstration: The After-treatment of Bromide Prints. Thomas A. Dodd.
21	Gospel Oak .....	Demonstration with Velox Paper. Messrs. Griffin & Sons.
21	Hackney .....	Development. Jno. H. Gear.
21	Iale of Thanet .....	Hand-camera Work with the View to Making Enlargements. John H. Gear.
21	Leeds Photo. Society .....	Instantaneous Photography. H. B. Buckley.
21	Lewisham .....	Hints on Printing. T. P. Rogers.
21	Rotherham .....	Photo Squeegee Work. J. Leadbeater.
21	Royal Photographic Society ..	Demonstration with Violet Electric Waves for Actuating Photographic Apparatus, and for Photographing Lightning in Daylight. F. H. Glew.
22	Oroydon Camera Club .....	Practical Notes on Outdoor Work with the Camera. Rev. A. H. Blake.
22	Leeds Camera Club .....	Exposure and Development. The Members.
22	Photographic Club .....	Cumberland Fells and Lead Mining. W. D. Welford.
23	Ashton-under-Lyne .....	Class for Beginners: Trimming and Mounting.
23	Camera Club .....	Some Eccentricities of the Law of Copy-right. H. Bentwich, LL.B.
23	Liverpool Amateur .....	Yorkshire Dales. G. E. Thompson.
23	London and Provincial .....	Open Night.
23	Oldham .....	Stereoscopic Photography. W. A. Hepburn.
23-25	Woolwich Photo. Society .....	Annual Exhibition.
24	Croydon Microscopical .....	The Selection of a Suitable Printing Process. J. A. Sinclair, F.R.P.S.
24	Plymouth .....	Demonstration: The Platinotype Process. H. J. Hissett.
25	Birmingham Photo. Society ..	Fourteenth Annual Exhibition. Private View.
25	South London .....	Last Day for Delivery of Pictures.

### ROYAL PHOTOGRAPHIC SOCIETY.

FEBRUARY 14.—Annual General Meeting, Mr. Chapman Jones, F.I.C., F.C.S., in the chair.

#### NEW MEMBERS.

Fifteen candidates for membership were nominated, and six, nominated at the last Ordinary Meeting, were elected.

#### AFFILIATION.

The HON. SECRETARY announced that the Brierly Hill and District Camera Club and the Ludlow Photographic Society had been admitted to Affiliation.

#### THE REPORT OF THE COUNCIL.

The CHAIRMAN moved the adoption of the Report of the Council for the year 1898, which was taken as read.

Mr. T. SEBASTIAN DAVIS seconded the motion, remarking that the report showed that the Society was in a most satisfactory condition. He called particular attention to the following paragraph:—

"Since the Crystal Palace Exhibition there have been signs of a more or less general desire that the Society's Annual Exhibitions should be more representative of photography generally than has hitherto been usual. The favourable reception given to the remarks on this subject by the Earl of Crawford in his Presidential Address encourage the Council to believe that a larger and more comprehensive Exhibition would be desirable if it can be carried out under arrangements which would secure the Society against loss. With the scheme of new premises in hand they have hesitated to bring this subject forward, but it is one which will have to be dealt with very soon, and they would be glad to learn the general feeling on the subject."

He expressed the opinion that the Exhibition should be fully representative of all classes of pictures produced by photography, and said that, although on the last occasion most of the exhibits were very interesting and suitable, there was a lamentable dearth of examples of many phases of photography, especially of portraiture and landscapes of an ordinary and every-day character. He considered also that a greater liberality in the distribution to members of complimentary tickets for the Exhibition would result in an ultimate gain to the Society, as most of the persons by whom such tickets were used would purchase copies of the catalogue. He thought it was not altogether satisfactory that only eighty members had exhibited, and suggested that some preference should be given by the Committee of Selection to pictures sent in by members of the Society, subject to the maintenance of a certain standard of excellence.

The resolution was then put, and carried *nem. con.*

#### THE BALANCE-SHEET.

Mr. G. SCAMMELL (Hon. Treasurer) moved the adoption of the balance-sheet, upon which he made a few remarks. The Society started the year with a credit balance of 32*l.*, and finished with 138*l.* in hand, the liabilities remaining practically the same, 144*l.* as against 143*l.* The amount received as entrance fees and subscriptions was 898*l.*, the largest sum received under that head within his recollection. In 1890, when he was one of the Auditors, the item was 392*l.*, and the increase had gone on steadily from year to year. There was a slight decrease in exhibition receipts of 18*l.* 13*s.* 4*d.*, but there was, on the other side, a decrease in expenditure of 42*l.* 15*s.* 6*d.*, so that the net loss was only 10*l.* 19*s.* 2*d.*, as against 45*l.* 1*s.* 4*d.* in 1897. With regard to the Crystal Palace account, including the balance brought from 1897 (48*l.* 9*s.* 7*d.*), the account about balanced. There was a deficiency, but, owing to the action of Mr. F. Bishop, the amount required was subscribed by Messrs. Marion & Co., Dallmeyer, Ross, Beck, Swan, Wellington, and other exhibitors, to whom the Society was much indebted. The guarantee fund had already reached the sum asked for, and would see the Society safely through the first three years at the new premises in Russell-square, including furnishing. The expenditure had remained about the same as before. With regard to the Affiliation, there were now over eighty societies affiliated, representing some 6000 members, and, having regard to the work which was being done under the auspices of the scheme, the Council had decided to allocate to the purposes of the Affiliation two-thirds of the amount of the subscriptions received from the societies, instead of one-half as hitherto. Mr. Scammell added that the Affiliation scheme entailed considerable expense upon the Society, and that the suggestion which had been made, that it was run solely for the Society's benefit, was quite erroneous.

Mr. J. SPILLER seconded the motion, and congratulated the Treasurer upon having been able to make ends meet after a year of unusually ambitious enterprise.

The motion was then put and carried.

#### ELECTION OF OFFICERS AND COUNCIL.

Mr. T. SEBASTIAN DAVIS read the report of the Scrutineers, announcing the result of the election of officers and Council as follows:—*President*: The Rt. Hon. the Earl of Crawford, K.T., F.R.S.—*Vice-Presidents*: Captain W. de W. Abney, C.B., D.C.L., F.R.S., F.R.A.S.; Messrs. T. R. Dallmeyer, F.R.A.S.; Chapman Jones, F.I.C., F.C.S.; and Sir H. Trueman Wood, M.A.—*Hon. Treasurer*: Mr. George Scammell—*Ordinary Members of Council*: Messrs. R. Child Bayley, T. Bedding, T. Bolas, C. H. Bothamley, F. A. Bridge, A. Cowan, W. E. Debenham, A. Haddon, F. C. Lambert, A. Mackie, J. W. Marchant, J. A. Sinclair, J. Spiller, J. W. Swan, E. J. Wall, H. Snowden Ward, L. Warnerke, Colonel J. Waterhouse, J. B. B. Wellington, and H. Wilmer.

#### THANKS!

Mr. CLAPTON proposed a vote of thanks to the officers and Council for their valuable services to the Society during the past year, and the proposal, having been seconded by Mr. FRESHWATER, was carried by acclamation.

Similar compliments were paid to the Auditors and Scrutineers, and the proceedings then terminated.

#### PHOTOGRAPHIC CLUB.

FEBRUARY 8.—Mr. J. R. Williams in the chair.

A discussion took place as to the reason for a decided yellowing which had taken place in some bromide frontispiece illustrations in certain volumes which Mr. H. Vivian Hyde laid before the meeting. The point attracting particular attention was the fact that the yellowing only appeared to have occurred where certain printed matter came into contact with the print, that is, so far as a piece of tissue paper would allow of this, and the question arose as to whether the discolouring was consequent upon some faulty manipulation or whether it was attributable to the influence of the printed paper. The latter seemed the more reasonable explanation, seeing that, if it were one of process, the degradation of the print would be, or ought to be, genuine. Accepting the suggestion that the printer's ink was responsible, it was peculiar that no impression of the printed matter was discernible, its action, if any, being so general as to show upon the bromide print no trace of the whereabouts of the white interspaces.

The subject of gold toning and the average quantity of gold left in exhausted baths came up, and was discussed in a conversational manner for some time.

Mr. WELFORD thought that a greater amount of gold was recoverable from acetate or borax baths than from sulphocyanide baths, although there might be the same quantity present.

Mr. STRETTON stated that the commercial gold chloride was nothing like the home-made salt. He dissolved a nugget weighing 63.5 grains, and made up his toning solution. After three years' very frequent use he reduced the gold from the bath, and from the residue got back 32 grains of the pure metal.

Mr. HYDE inquired whether there was any means of discharging the yellow stain which frequently occurred when reducing lantern slides with ferricyanide?

It was thought that once a stain occurred it was almost an impossibility to free the plate of it. It was caused by the use of too strong a solution in the first instance, and, should washing be unduly deferred, the effect was much the same. There was some uncertainty as to which was the better way, in reducing negatives, slides, &c., namely, to apply the dilute ferricyanide to the plate as it emerged from the hypo fixing bath or to wash the plate and mix the ferricyanide with the hypo. It was recognised that the amount of hypo in a film taken direct from the fixing bath was a very uncertain quantity, and for this reason the balance of opinion was favourable to the alternative method.

**Brixton and Clapham Camera Club.**—February 7.—Mr. E. Dockree gave a lantern exhibition of miscellaneous slides—architectural, landscape, flower studies, &c.—which were well received. Mr. Mongiardino then tried acetylene as a lantern illuminant, which seems very suitable for small pictures. Tylar's new Aladdin lamp attracted attention.

**Croydon Camera Club.**—The Ninth Annual Meeting of the above, held on Wednesday, February 8, at the Club-rooms, 108, George-street, Croydon, disclosed a very flourishing state of affairs. The membership is now in the second century, and bids fair to complete the 200. The cash balance and assets amount to over 80%, liabilities none. Thirty-two evening meetings for demonstrations, &c., were held, at which the average attendance was twenty-four. Five important excursions were held, at which the average attendance was eighteen. A number of smaller outings were also organized. The report and balance-sheet having been adopted, the meeting appointed the following officers and councillors for the years 1899-1900. On the motion of Mr. JAMES PACKHAM (in the chair), seconded by Mr. JOHN SMITH, Mr. Hector Maclean, F.G.S., F.R.P.S., was unanimously re-elected President. *Vice-Presidents:* The Mayor of Croydon (Councillor G. J. Allen), the Right Hon. C. T. Ritchie, M.P., Sir David Salomons, Bart., Sir Frederick T. Edridge, and Mr. James Glaisher, F.R.S.—*Council:* Messrs. W. Burn, A. W. Hirst, A. C. W. Irving, A. E. Isaac, G. W. Jenkins, Councillor J. Noaks, J. Packham, F.R.P.S., J. Smith, J. C. Taylor, S. H. Wratten, G. W. Watson, and A. Willcocks.—*Hon. Treasurer:* Mr. H. E. Holland.—*Hon. Lanternist:* Mr. A. E. Isaac.—*Hon. Secretary:* Mr. W. H. Rogers, 108, Holmesdale-road, South Norwood, S.E.—*Hon. Assistant Secretary:* Mr. Atherton Aldis, 30 Surrey-street, Croydon. On the reappointment of Mr. Isaac to the post of Hon. Lanternist of the Club, the PRESIDENT, before putting the resolution, speaking on behalf of the whole Club, addressed a few words conveying the appreciation felt by all members at the great service which Mr. Isaac had rendered the Club. From the first day of its foundation he had worked on its committees, and had stuck to it through all its juvenile troubles. Of late years the Club had been free from its earlier anxieties, but without Mr. Isaac to give so much of his time to managing the lantern at their many lantern nights it would have been perhaps impossible for the Club to have established the long series of public lantern displays which have been so well appreciated. He (the speaker) had much pleasure in testifying to the invariably flattering terms in which all their many lecturers had always spoken of the effective and efficient way in which Mr. Isaac handled everything connected with the lantern. As a token of the members' esteem and gratitude the President then handed Mr. Isaac a handsome Tantalus spirit case, engraved with a suitable inscription, and bearing the recipient's monogram wrought in silver. The assemblage's hearty cheering on Mr. Isaac rising to acknowledge the presentation testified to the warmth of the members' esteem for the Hon. Lanternist. Subsequently the meeting decided to endorse the late Council's resolution to hold the Club's third public exhibition of photography in October of the present year. At the instance of Messrs. ROGERS and PACKHAM, the meeting further resolved to hold the Ninth Annual Dinner on Wednesday, February 22, and that a *Soirée* should also be given during the coming Exhibition.

**Kingston-on-Thames and District Photographic Society.**—February 6.—Mr. H. M. C. SPRUNT delivered a lecture, entitled

#### A CRUISE TO THE LAND OF THE MIDNIGHT SUN.

The chief difficulty in Norway, said the lecturer, from a photographer's point of view, is not so much to know what to take as to decide what not to photograph, so numerous are the pretty bits to be seen at every turn. In crossing the North Sea in summer there is little to be feared from the dreaded *mal de mer*. He had made the passage four times, and on only one occasion was it sufficiently rough to be unpleasant. The first port of call was Stavanger, the principal object of interest here being the cathedral, portions of which are said to resemble Winchester. Stavanger, like most Norwegian towns, is composed chiefly of wooden buildings, picturesque in appearance. Close to the town is a small lake covered with water lilies, and it was here the lecturer secured his first photograph on Norwegian soil, the operation being closely followed by a crowd of nearly one hundred girl and boy peasants. At Sundal many charming pictures of mountain and torrent were obtained, these eliciting considerable applause as they were projected upon the screen. The Boudhos glacier and waterfall were next visited. The glacier is an immense expanse of ice and snow, covering an area of twelve square miles, and, owing to the numerous ravines, dangerous to cross unaccompanied by a guide. The lecturer was fortunate in securing an excellent picture of the waterfall, showing the spray

from the falling water playing across the carriage way. Referring to railway travelling, he mentioned, incidentally, that a great contrast existed in comparison with British lines. There is no undue haste in the departure of a train, ample time being allowed for the selection of a seat; while, on the journey, the train is often delayed to satisfy the whim of some tourist passenger. As an instance, he cited a case wherein he and his camera played a prominent part. Travelling from Bergen he encountered a peasant bridal party, and, being desirous of including a Norwegian bride in his series of pictures, permission was obtained from the parties immediately concerned, and the photograph taken at the next station, where the train was purposely detained fifteen minutes. A Norwegian bride can usually be distinguished by her peculiar head-dress, resplendent with gold and silver ornaments. When the family can afford it, this head gear is retained, and handed down from mother to daughter, each succeeding generation adding further metallic embellishments. Numerous other slides depicting the various phases of Norwegian life, manners, and customs, Laplanders and their dogs, and the beauties of the country were passed through the lantern, concluding with a capital photograph of the midnight sun.

**Lewisham Camera Club.**—February 7.—Mr. H. L. DAVIS gave a practical demonstration on the

#### TRIMMING AND MOUNTING OF PRINTS.

For trimming small prints he used a shape cut from hard wood, with a rectangular opening to enable it to be correctly adjusted over the print, and preferred a hard wooden surface for cutting upon. Having trimmed several prints, he proceeded to mount them, using stiff starch paste, which was spread over the paper by means of a piece of sponge, thus obviating the possibility of a bristle getting between the print and mount. The advantage gained by using a sponge when dealing with large surfaces was obvious on seeing the ease and rapidity with which Mr. Davis spread the mountant over the back of an enlargement. He then proceeded to make a cut-out mount for this, and in a few minutes cut a perfect bevel-edged opening in a suitable board, using an ordinary penknife, and having as a guide a steel straight-edge, which, owing to its weight, did not require an assistant to keep it steady.

**North Middlesex Photographic Society.**—February 6, the President (Mr. Mummery) in the chair.—Mr. H. STUART (Hon. Secretary) explained, according to a promise at the last meeting, the function of a condenser in the optical lantern. He had prepared several diagrams, which illustrated very clearly what was required of the condenser. To get the maximum efficiency, the rays from the source of light must be brought to as small a compass as possible within the projecting lens, so that all the light collected by the condenser may be used. If the focus of the latter is too long, so that the cone of rays is brought to a focus beyond the lens, all the rays will not pass through unless the light is withdrawn further from the condenser, with consequent loss of light on the screen.

**Putney Photographic Society.**—February 6, Mr. Francis T. Beeson, F.R.P.S., in the chair.—Mr. EDMUND A. ROBINS, of the Eastman Company, gave a demonstration of the

#### DEVELOPMENT AND TONING OF SOLIO PAPER.

After giving an explanation of the process, the lecturer proceeded with the development of prints that had been only slightly printed, putting them, without previous washing, into the developer: Hydroquinone, 24 grains; citric acid, 60 grains; acetate soda, 1½ ounces; water, 30 ounces. These he developed up to about the same depth as when ordinarily printed, and, after a thorough washing, toned them by means of the sulphocyanide bath, and fixed as usual. The lecturer mentioned that, as an alternative, the combined toning and fixing bath could be used. Systematic toning of Solio paper was also demonstrated, by which any desired tone can be obtained by varying the amount of prints per grain of gold used for toning, thus a solution containing 1 grain of gold chloride to 10 grains of ammonium sulphocyanide will tone six half-plate prints to a purple-black, twenty prints to the same amount of gold giving a brown tone. After the demonstration samples of Dekko paper were handed round, this being a paper which may be exposed and developed in weak gas-light, hydroquinone and metal being recommended for development. Any colour, from red to purple, can be obtained by exposing until the detail is just visible and developing in the following solution, after thoroughly washing: No. 1. Citric acid, 2½ ounces; ammonium carbonate, 1 ounce; water, 10 ounces. No. 2. Sulphite of iron, 2½ ounces; water, 10 ounces; sulphuric acid, 10 drops. For use, add one part of No. 2 to three parts of No. 1, and not *vice versa*. The prints are thoroughly washed and fixed in the usual hypo bath.

**Derby Photographic Society.**—February 7, Annual Meeting.—After the transaction of the usual business, the VICE-PRESIDENT made some interesting remarks on the subject of

#### PICTORIAL PHOTOGRAPHY.

He expressed the hope that his year of office might see a distinct advance in the work of the Society, and that members would endeavour to rise above the old-fashioned photography which aimed at the representation of crowds of detail. Several years ago Emerson began to preach the value of what was now known as pictorial photography, as compared with the prevalent style of rendering too much detail, and that in sharp focus; but, for many years, he had been like one "crying in the wilderness," and his doctrines had not been adopted until recent years. Even now the old style found most favour with the general public, but it was for photographers to lead, and members of this Society should devote their attention to the pictorial work which alone was of value for exhibition and competition purposes at the present day. He urged members to show "evidence of intention" in their work, something to appeal beyond the eye to the higher faculties, and not to content themselves with mere views of pretty scenes, which were nothing beyond records and maps. Mr. Bland went on to call attention to the Exhibition which it is proposed to hold in the Art Gallery in June or July. He said that members of the Society would be expected to loyally support the Committee, who had the matter in hand, and justify the action of the Corporation in catering for them. If members did not do this, and the

Society did not make a good show, there would be very little prospect of the Corporation again bearing the expense of such an Exhibition. Subsequently Mr. Bland passed round a portfolio of beautiful photographs by some of the best workers belonging to one of the Postal Camera Clubs.

**Dundee and East of Scotland Photographic Association.**—February 3, Mr. W. H. Tittensor, jun. (Vice-President) in the chair.—Dr. LUMSDEN, of the University College, Dundee, delivered a lecture, entitled,

#### HOW LIGHT PRODUCES CHANGE.

The lecturer showed that there were three denominations of matter. Masses obeying the force of gravitation, molecules held together by cohesion, and atoms bound by chemical affinity. Molecules were clusters of atoms which could be separated and rearranged, and chemical change was simply a changing of partners. Experiments to illustrate change produced by heat, electricity, sound, and light were shown. The nature of light was next considered. All sources of light were places of intense motion, and the disturbance in the ether so caused was propagated to vast distances, and could produce a similar motion on a suitable receiver, such as the eye or a photographic plate. On a photographic plate there were groups of molecules suspended in gelatine. Light caused a vibration which overcame the chemical affinity; there was a rearrangement, and on the plate were now two substances instead of one. A developer was a solution sent to search for the altered particles, and to fix them. The action of various kinds of light in producing chemical change was shown to explain the difficulty experienced in producing an orthochromatic plate. The CHAIRMAN then referred to the loss the Association had sustained through the death of Mr. G. G. MacLaren, and submitted the following draft of minute, which was approved by the meeting: "The Dundee and East of Scotland Photographic Association, in expressing its sense of the loss it has sustained through the death of Mr. G. G. MacLaren, late senior Vice-President, desires to record the valuable services that Mr. MacLaren so frequently rendered to the Association. A regular attendant, both at its ordinary and its Council meetings, his suggestions and remarks were invariably practical and helpful. He ungrudgingly placed his professional experience and skill at the disposal of the Council, and it was largely through his interest that the club-rooms were instituted, and through his assistance that they were equipped. His colleagues will long remember his uniform and quiet courtesy, and recognise the good influence that he always brought with him to their meetings. The Association instructs the Secretary to enter this testimony to Mr. MacLaren's worth in the minutes of this meeting, and to convey to Mrs. MacLaren and her family, along with a copy of this resolution, an expression of the deep sympathy felt by every member for them in this bereavement."

#### FORTHCOMING EXHIBITIONS.

1899.			
February 17, 18	.....	Photographic Society of Ireland. Hon. Secretary, 35, Dawson-street, Dublin.	
" 17-23	.....	Northampton. E. J. Felse, 53, Adams-avenue, Northampton.	
" 17-25	.....	Edinburgh Photographic Society. Hon. Secretary, J. S. McCulloch, 2, George-street, Edinburgh.	
" 18	.....	West London.	
" 21-24	.....	Hastings and St. Leonards. Exhibition Secretary, A. Brooker, 21A, Wellington-place, Hastings.	
" 23-25	.....	Woolwich Photographic Society. Hon. Secretary, F. W. Machen, 161, Griffin-road, Plumstead, S.E.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### PRINTERS.

##### To the Editors.

GENTLEMEN,—Seeing your article in last week's BRITISH JOURNAL re fading of prints, may I trespass upon your space to say that I thoroughly endorse your remarks as to carelessness. I am a printer of sixteen years' experience, and have been for some years a head printer in a good firm, but, alas! it is only too true that boys and girls are left to do the work,

which should only be intrusted to a trustworthy and experienced man. I have had to give up many an hour of my own meal time, simply to stay and see that the washing of prints has been properly done, or I have proved that they are scamped over with one change, not about twenty minutes in a dish of running water, and a not over clean dish-either; I don't get faded prints now I see personally after the washing of them, and my experience tells me that this is the case in the majority of firms. Let them pay a good printer a living wage, and get a man they can trust.—I am, yours, &c., PERMANENT.

#### THE GLASGOW INTERNATIONAL EXHIBITION.

##### To the Editors.

GENTLEMEN,—I am directed by the Council of the Glasgow and West of Scotland Amateur Photographic Association to ask you to contradict the statement made in your last issue that the Association has decided to have nothing to do with the International Exhibition of 1901. The matter referred to has not even been discussed by the Association.—I am, yours, &c., WM. GOODWIN, Hon. Sec.  
3, Lynedoch-street, Glasgow, February 14, 1899.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

#### PHOTOGRAPHS REGISTERED:—

H. W. PENFOLD, 100, High-street, Ashford, Kent.—Photograph of scene of Biddenden murder, February 5. Photograph of J. Whibley's house, Biddenden.

A. W. YALLOP, 198, High-street, Gorleston, near Great Yarmouth.—Three Photographs of Scotch fishing boats at sea. Photograph of rough sea on stone breakwater at Gorleston. Photograph of tug and schooner entering the harbour at Gorleston during a gale. Photograph of fishing vessel sailing into Gorleston Harbour in a rough sea.

PROVINCE; W. EDMUND WALLIS; H. PENFOLD; and others. In our next.

JOHN BOOL.—Thanks for your letter.

PHOTO-PHOENIX.—Approximately three grammes of zinc, and say half to one ounce of acid.

GILBERT STRINGER (Colchester).—Thanks; but the matter is hardly one of general interest.

PRINTER.—Add, slowly, a solution of sulphate of iron 1:4 (about) to the bath until no more gold is precipitated.

G. BANKART (Leicester).—Thanks for the suggestion. We will endeavour to meet your wishes at an early date.

E. BULLOCH.—We are much obliged to you for the report. You will see a reference to the matter in Ex Cathedra.

A. W. W.—Try King's solution for the purpose. It is sold by Marion & Co., and we have found it very effective for the purpose.

A. B. (Burton-on-Trent).—The nitrate of silver will do very well. Pure chloride of sodium will be better than common table salt for the emulsion.

C. A. WAITE, of 17, Clifton-street, Wolverhampton, inquires for the address of a photographic assistants' union. We know of no such body. Do any of our readers?

PAINTER.—We have not published any such article. In the case you cite if the business shows a clear net yearly profit of 50% or more, it might not be dear at the price.

W. D. J.—There is no book current on the subject that we know of. Bigelow's *Album* might be met with second-hand if advertised for. It treats of posing and lighting.

J. ROBINSON.—Possibly the incandescent electric light system would be the best. Messrs. Adamson supply the fittings, but we could not tell you where it could be seen in operation in your town.

SPOTS AND STAINS: W. & Co.; T. BAKER. See leading article in last week's issue. The marks on the latter's prints are obviously due to the prints being allowed to stick together while in the fixing solution.

PRINTER.—Your letter was unnecessarily offensive, and was consigned to our waste-paper basket. Do you not think you could discuss the pros and cons of a printing process without penning insulting remarks about one of our most skilful photographers?

VARNISH TROUBLE.—S. NEWTON. If the varnish does not dry, and behaves as you say, there is little doubt but that there is hyposulphite in the film, and a good deal too. The varnish we know to be good, so try more perfect washing of the plates.

**HENRY SHORT.**—Bromide and platinotype prints make very effective transparencies; but you must recollect that the action of light, of which you say there is plenty, on the paper, is a darkening one. Can you not fill the space with glass transparencies? Paper, we fear, would not last long enough to please you.

**SILVER INTENSIFICATION.**—**ALAN** says: "When intensifying gelatine negatives with mercury and cyanide of potassium with silver nitrate, may the cyanide silver bath be used more than once, or should a new bath be made each time?"—The same solution may be used over and over again. No need for a new solution each time.

**UNMOUNTING PRINTS.**—**WALLACE** asks how he can get some prints off their mounts that he knows were mounted with either gelatine or glue.—Soak the prints in cold water for an hour or two until they are perfectly saturated, then transfer them to warm water, about 100° Fahr. In a few minutes the prints can be easily stripped off.

**FOGGED PLATES.**—**T. BURKE.** The only way we can account for the fogging is that the light used, either in filling the slides or in the development of the plates, was not a safe one. We would suggest that you see to that. You may rely upon it that the plates were right, also that the developer, if compounded as stated, was quite right; so also was the method of using it.

**C. TYLER.**—Probably the process over which most command is obtainable is that of Mr. Chapman Jones. It is, briefly, to whiten the image with bichloride of mercury and redevelop with ferrous oxalate. If we remember aright, Mr. Chapman Jones, some years ago, showed that the intensity of a thin negative could be built up in this manner to an almost unlimited extent.

**AGREEMENT.**—**R. C. C.** It is a matter that we can hardly advise upon; but it seems to us that it would be unwise to take a place on only a three-years' agreement, and on the strength of that only to build a studio, &c., that will cost from 100% to 150%. The rent is low, it is true, but where will you, and the business you may have built up, be at the end of that term? Our advice is, insist on a longer term.

**GELATINE PAPER.**—**M. R.** inquires where he can obtain some paper with an enamelled or baryta coating which has been coated with plain thin gelatine, like the double transfer paper for carbon printing, but without chrome or other alum.—We do not know if such a paper is stocked by any one. The Autotype Company, or Elliott & Son, are the most likely people. If they do not stock it, they will probably make it to order.

**FAULTY BROMIDE PRINTS.**—**B. HIGGS** complains of the colour and hardness of his bromide prints. The prints enclosed show that they are all under-exposed, and have been much forced in the development. The green tint is to be accounted for in the use of too much bromide in the developer. A longer exposure and less forcing in the development will give more harmonious results and less chalky whites and buried shadows.

**ENAMELLING.**—**L. E. W.** says: "The enclosed enamels, you will observe, have dull marks on the surface, this occurs occasionally. Will you kindly tell me the cause, also how to avoid them in the future?"—Some of the marks are due to air being imprisoned between the print and the glass, when they are squeezed down upon it. Others, though fewer, are caused by solid particles such as dust adhering to the print, or in the water getting imprisoned.

**COPYRIGHT CASE.**—**F. SARGENT** says: "In your issue of December 23 you have entry of two photographs registered by me. They have since then been reproduced in two different newspapers without my consent. Can you advise me what to do in the matter?"—In reply: The case is very simple. Employ a solicitor to demand payment for the infringement—we would suggest ten guineas for each photograph. If the photographs were registered before the infringement, the newspapers, metaphorically speaking, have not a leg to stand on, and will be glad to compromise.

**SALE OF BUSINESS.**—**W.** says: "I have agreed to purchase a business, and have paid a deposit, but since doing so I have learnt that the business and the returns have been entirely misrepresented to me, indeed it is little, if any, less than a fraud. I certainly shall not complete the purchase. But can you tell me if I must sacrifice the deposit money I have paid?"—If the deposit has been obtained from you by fraudulent misrepresentation, you can certainly recover it back. We should advise you to place the matter in the hands of a solicitor. In reply to the second query, we know nothing of the party.

**CLEAR HYPO SOLUTION.**—**F. E. G.** says: "Will you kindly inform me what I should put into my fixing solution (hypo) to prevent it discolouring so quickly? I am using it for fixing bromide prints, and to keep the whites pure I like the hypo solution quite clear, but I find this requires three casks of hypo instead of one."—The best way of keeping the fixing bath clear is to wash the prints free from the developer before they are put into it. The "acid fixing bath" keeps clearer than the plain solution of hyposulphite of soda, but many object to its use on the score of the prints fixed in it being thought less permanent.

**COPYRIGHT.**—**CARBONETTE** says: "I have recently purchased a business, including stock in trade, goodwill, and negatives, and all apparatus appertaining to the photographic trade. Among the negatives is one of a county nobleman, now deceased, which is a copy of an enlargement made by myself, along with the assistance of my predecessor, from one of his own negatives. Can I copyright same, and prevent another party in the town from selling copies, as this party, by some means, copied the enlargement which is the work of my predecessor and myself. The original negative, you will understand, was taken by my predecessor?"—In reply: We think you are powerless in the matter unless a print from the original negative was registered and an assignment of copyright made to you by your predecessor. This is stating the law of the case, as we understand it, from the Copyright Act.

**BOOKS WANTED.**—**E. A. METCALFE** says: "Would you kindly inform me where I can purchase the following books—illustrated, if possible: 1, on lighting and posing; 2, working up in black-and-white; 3, retouching? Please state prices."—In reply: There is no work extant on posing and lighting. *Artistic Lighting*, by Inglic, published by the Photo-Beacon Company, Chicago, price, we think, one dollar, might suit you. As for the others, *Working up Enlargements* (Boal), published by Percy Lund & Co., and *Retouching* (by Johnson), published by Marion, might answer. We do not know the prices; you had better order the books through a dealer.

**WATER-GLASS.**—**H. B.** says: "I bought this substance in the form of a clear white treacle. When I use it as a varnish, it becomes milky and remains soft. Why is this? Ought I to subject it to heat? How can I make a solution of it? What is the proper solvent? Referring to p. 85 of last week's issue ('Fireproof Wood'), what is the effect of adding am. to water-glass under ordinary circumstances, i.e., without pressure and vacuum? I find great difficulty in getting any information about water-glass."—Both the silicate of soda and silicate of potash are known as water-glass, and they may be diluted with water. The only use we know of water-glass in photography is as a substratum on glass plates, as in the collotype process, mixed with albumen and generally beer. We have not heard of its being used as a photographic varnish. It is used for making wood, &c., fireproof, as in the paragraph referred to, and also for coating damp walls prior to papering them.

**AN ASSISTANT'S DILEMMA.**—**W.** says: "Some few months ago you were good enough to answer a query of mine as to the quality of some retouching I sent you. You then expressed the opinion that it was decidedly above the average. This was about April or May last year. I venture now to write you to ask whether you could advise me further in the following matter: I have been engaged in photography for the past seven and a half years, and, until April 1897, I did very well in the matter of engagements, but since then I have not done twelve months' work, having only had two season engagements. I have always been used to first-class work, and I really cannot understand how it is that I cannot obtain an engagement. Advertisements in your widely circulated paper bring no answers, and I really don't know beyond this how to obtain an engagement. I have written to many firms in addition. Are there many more in my position in the profession, I wonder? I hope not. If you could give me a hint or two, I should be greatly obliged."—In reply: We can only suggest personal applications to such firms as are likely to require the services of a good retoucher. But in these times retouching by itself is, in our opinion, barely sufficient to rely upon for a living; combined with first-class operating, printing, &c., it should enable a man to secure a good position. We are sorry we cannot be of more help in the matter.

**STUDIO, &c.**—**C. F. A.** says: "1. A friend of mine is erecting a studio which is to stand in open space with north-east aspect (see plan enclosed for measurements). He is anxious to know if it would be a great advantage to raise the ridge so as to give an angle that would keep the sun off at its highest altitude. 2. What angle would that require to be? 3. In working the bigum process by the old method of mixing the gum, pigment, and bichromate together, is it essential that the coating should be done in yellow or ruby light, or could it be done with lamp or gas light unscreened? 4. When making enlargements from a negative that is showing grain slightly, is it advisable to use a small stop, or should it be done with the longest stop compatible with definition? 5. What are the conditions for obtaining a copyright for a photograph, and to whom should I apply?"—1 and 2. We should prefer the studio shown in the first sketch, not the suggested alteration. A boarding a couple of feet high along the ridge would answer all the conditions of the "suggested improvement." 3. Yes. 4. The smaller the stop used the more pronounced will be the grain in the enlargement. When the grain is very coarse in the original, it is not unusual to make the enlargement with the lens a trifle out of focus, so as to hide it to an extent. 5. By registering it at Stationers' Hall. If you send us three copies with 1s. 7d. in stamps, we will effect the registration for you.

**MODERN FALLACIES, &c.**—**A. W.** writes as follows: "As one of the old workers, who you say are getting fewer and fewer (and I am, unfortunately, one of them) I read with great interest your recent leader on modern fallacies about old processes, because THE BRITISH JOURNAL OF PHOTOGRAPHY is the oldest journal, and always has been recognised as being authentically *au courant* with the old processes. When they are quoted, they should be quoted correctly, and not be misleading to historians in the future, and that is my reason for writing—more particularly with regard to the confusion of the sel-d'or with the old combined toning and fixing baths. In his letter on this subject in your issue of the 2nd ult., which I see you have not noticed, Mr. J. Pike further confuses the subject by saying, 'It is easy to see that from the simple solution to one containing phosphate of soda and an excess of hypo, with the object of combining the operations, was only one step. As a matter of fact, phosphate of soda was never used, either in connexion with the sel-d'or bath or the old combined toning and fixing bath. The former was hyposulphite of gold, and nothing else. The latter was simply a solution of hyposulphite of soda with chloride of gold added, no other salts, except, when this bath was first made, some added about double the quantity of nitrate of silver. This latter was always omitted when the bath was replenished; then only more hyposulphite of soda and chloride of gold was added. My reason for writing is, as one of the old hands, our methods of working should not be misrepresented. I might add that phosphate of soda in toning was only introduced after the alkaline system was adopted—the carbonate, acetate, citrate, borax, *et hoc genus omne*."

## EX CATHEDRA.

LAST week, when reviewing a catalogue of cinematograph films (see page 108), we took the opportunity of throwing doubt on the wisdom or expediency of selecting sacred subjects for purposes of popular photographic illustration. Aside of the fact that photography obviously does not provide the ideal graphic agency for conveying to the world an individual conception of how the scenery and *dramatis personæ* of the Biblical drama really appeared and comported themselves, there is, as we pointed out, the risk of offending the finest, most cherished susceptibilities of vast numbers of persons by making the camera the means of depicting what are obviously life-model representations of incidents possessing, to such persons, the highest religious significance. We believe there is something very widely repugnant in the idea of persons posing before a lens in sacred character, and that, no matter how skilfully and reverently the photographs have been produced and treated, the incongruity and doubtful taste of nineteenth-century persons presuming to make up as actors or participators in dramatised portions of what so many millions of persons regard

as the Divine redemption of the human race, can never be obliterated from the minds of those called upon to contemplate the photographic results.

THE observations that we made a week ago have induced a correspondent to direct our attention to the February number of our highly esteemed contemporary, the *Photogram*, which contains three photographs purporting to represent the Crucifixion and the Entombment, by one of the most intellectual photographers yet produced by the United States—we mean Mr. F. Holland Day—whose pictorial work for the last two or three years has been favourably known on this side of the Atlantic. Mr. Day also writes a brief article called, "Sacred Art and the Camera," in which he pleads for the liberty of the photographer to illustrate subjects usually reserved for painters and draughtsmen. The titles of Mr. Day's photographs are: *Into Thy Hands, The Entombment, and I thirst*; and we mean no offence when we say that to us, as photographers, they are exceedingly repellent, in virtue of their obvious reliance upon "the art" of the person who made or built them up. The rutless lens reveals every little trick or artifice employed in "faking up" the originals; and we confess it is with something of a shock that we contemplate these photographically vamped-up representations of what are so generally regarded as three of the most moving incidents of the World's Tragedy figuring in the pages of an illustrated magazine.

To the best of our belief and knowledge, sacred art, so called, has not yet inspired British photography. At the moment we can only recall three pseudo-sacred photographs publicly exhibited, a *Christian Martyr* and two *Magdalenes*, and this in an experience of about twenty years of the exhibitions. Those attempts were coldly received by the photographic public, and we cannot discover that any inducement has been forthcoming to other photographers to select even graver themes than those mentioned for lenticular treatment. We hope matters will remain so. The lens and the dry plate do not idealise as the painter or the draughtsman can or may. The very finest skill of the foremost British photographers, we are convinced, would break down at any attempt to divest a sacred subject, taken by means of the camera, of those insistent and cartographical

details which impart an element of repulsiveness, in our eyes to Mr. Holland Day's photographs—repulsive because we are conscious that the individuality of the originals has not been, cannot be, so completely masked or subdued as to destroy the mental persuasion that we are looking at the image of a man made up to be photographed as the Christian Redeemer, and not at an artist's reverent and mental conception of a suffering Christ.

\* \* \*

WE hope that neither Mr. Holland Day nor anybody else will misunderstand our motive in drawing attention to this matter, as to which we believe we give expression to sentiments almost universally entertained by British photographers. Not only for the reasons given are sacred subjects best denied treatment by the camera, but also in the interests of photography and photographers themselves, who would surely provoke the hostile opinion of the educated public by any appreciable attempt to deflect camera work from its legitimate paths. A moment's reflection will show that the scope opened up by allowing that sacred subjects are admissible for photographic treatment is practically illimitable, and that the possibilities of offending against the deepest susceptibilities and convictions of millions of minds are just as great. We trust Mr. Holland Day's example will not find imitators in this country, and that in his own it will speedily be recognised that the reasons for denying to "sacred art" photographic treatment are so numerous and weighty, that a very serious responsibility is incurred in ignoring or overlooking them.

\* \* \*

WE are much obliged to Mr. Hugh Penfold, photographer, of 100, High-street, Ashford, Kent, for a photograph of somewhat sombre interest. Readers of the newspapers will recollect that three weeks ago a man named John Whibley was shot dead by the rector's daughter in the schoolroom at Biddenden, Kent. This is a photograph of the scene taken shortly after the deed. Whibley lies prone on his back, immediately under a picture of the Good Shepherd. What appears to be blood stains the floor near his head; his hat and stick are placed on a form, and, besides the simple little educational items of the country schoolroom, there is also shown, lying on the table, a small hand basket which presumably belonged to the unhappy woman who stands charged with the murder. The photograph tells its own tale, and has quite a grim fascination for one.

\* \* \*

WE are informed that Mr. John A. Tennant, for some years past Associate Editor of *Wilson's Photographic Magazine*, New York, has resigned that post and formed a partnership with Mr. W. E. Ward, late of the *Photogram*, London. Messrs. Tennant & Ward are located at 289, Fourth-avenue, New York, and will, in a few weeks, begin the publication of a monthly photographic magazine, the *Miniature*, which is, we learn, planned along new lines, and will not clash with the existing photographic journals. The new firm will make a speciality of dealing at wholesale and retail in American and foreign photographic books, and will also have the American agency for a London firm of general publishers.

\* \* \*

WE are indebted to the Société Anonyme des Arts Graphiques of Geneva (formerly known as F. Thévoz & Co.) for a very fine

specimen of three-colour work, employed in a branch of printing production for which that process is undoubtedly well adapted, namely, poster work. The actual measurements of the picture before us are  $22\frac{1}{2} \times 16\frac{1}{2}$  inches—a very good size of block, and for which, notwithstanding its dimensions, a by no means considerable "openness" of grain has been chosen. The design is a striking one, boldly executed, and it depicts the inevitable fancifully garbed and flower-decked female holding an engraving tool in her hand and placed in association with a camera. The symbolism is obvious. The block is a very fine one, and we are pleased to have it as a specimen of what can be done in three-colour poster work.

### COLOUR FALLACIES.

To the Chemical Section of last year's meeting of the American Association for the advancement of Science Mr. Romyn Hitchcock contributed a paper on "The Modern Problem of Photography." That problem is, of course, colour photography. We have the text of Mr. Hitchcock's paper before us in the January number of an American contemporary, *Wilson's Photographic Magazine*, and, as no subject is of such importance to photographers and others as the reproduction of the colours of art or nature by means of the camera, it may be useful if we examine the latest contribution towards the solution of that very fascinating problem, with a view to ascertaining how many steps nearer the desired end it has taken us.

To begin with, we must assume that the American Association occupies towards the world of science in America a position analogous to that filled in Great Britain by our own British Association. Hence the subjects brought to the notice of such a representative body derive an additional importance from the mere fact that they are laid before those who have an authoritative acquaintance with the branch of science which is dealt with by a particular section, and who may therefore reasonably be supposed to take precautions to ensure that the matter as well as the manner of the papers read is, as the current jargon expresses it, "class enough" for the meetings.

Now, the fact that Mr. Hitchcock's paper was accepted by, and read to, a body of scientific men, taken in conjunction with its subsequent publication in a photographic periodical, compels us to scrutinise his remarks with a little more care and closeness than we should devote to the outpourings of an irresponsible writer for the general press, whose knowledge of what photography in natural colours is, or is not, is usually conspicuously less than his ability to write fluently, but with fatal inaccuracy, on the ensnaring subject. Moreover, the fact that Mr. Hitchcock has put forward certain very original theoretical ideas of his own supplies an even more cogent reason for paying every attention to his remarks.

As the result of observation, Mr. Hitchcock says he is convinced of two fundamental facts, "which indicate that the fond dream of the photographer (i.e., colour photography) will sooner or later be realised." Straightway let us give Mr. Hitchcock's fundamental facts set forth in Mr. Hitchcock's own words.

"1. Under proper conditions, perhaps under all conditions, the various colours of an object may impress themselves upon a photographic plate, each in its specific manner, although the plate shows no colour to the eye. If a plate is developed into a negative, the specific effect is retained and fixed in the plate, which still shows no colour.

"2. A print from such a negative, either on glass or paper, is also specifically impressed by the colours of the original object. As a result of this, the following phenomena may (*sic*) be observed.

"(a) The positive may show the colours of the original object distinct and permanent.

"(b) The positive may not show any colour, but it may manifest a selective action in imbibing colouring matters from coloured solutions, whereby the colours of the original object can be experimentally determined, or more or less correctly reproduced." Mr. Hitchcock's two fundamental "facts," which he totally omits to fortify by the production of evidence, leads him to ask if it is not possible "that the colourless film of a photographic negative may possess a molecular constitution in different parts corresponding to the colours of the object."

We are much afraid that our author's "facts" are merely the idle speculation of one who possesses only a superficial acquaintance with colour photography in its theoretical aspects, which his question about the possibility of the molecular constitution of a negative corresponding to the colour of the object only serves to throw into high relief. The Hitchcock theory of colour photography is just the sort of thing we should expect a fairly clever amateur to put forward after a year's dabbling in photography; but Mr. Hitchcock lacks the excuse of inexperience for fathering the supposition that a miracle is likely to happen in the evolution of a colour-photography process. An ordinary film of sensitive silver haloid in gelatine, exposed and developed in the usual manner, is just as likely, either itself to register the colours of the original or to transmit them to a prepared printing surface, as the moon is to yield a supply of green cheese to Sir Thomas Lipton for his many shops, or the obese inhabitants of the farmyard pigsty are to take unto themselves wings and fly. Nothing in the chemistry or physics of the subject can be found to bolster up Mr. Hitchcock's jejune fallacy. The wave theory of light, which, after all, is the basis of the whole philosophy of colour, will not parallelise with Mr. Hitchcock's crude ideas at any point. Zenker, Wiener, and others have insisted upon the use of sensitive recording agents, compared with which ordinary gelatine films are hundreds of times too thick and opaque. Carey Lea, of Philadelphia, is, so far, the only scientist who has attempted to produce colour on ordinary bromide films, but that was by direct chemical agency. Mr. Hitchcock is probably unaware that the Lippmann results are produced on absolutely colourless, structureless, films in which the proportion of silver haloid is so small that it is not perceptible to the eye; but even these pictures are only visible in light of a certain incidence, the colours are subjective rather than objective. In short, Mr. Hitchcock's idea that an ordinary plate "may" register colour, and "may" transmit it, can at once be dismissed as totally absurd, unreasoning, and unscientific.

The mischief which such wild ideas as those which we are here exposing are likely to do among photographers of greater lack of knowledge than their author is intensified when they are illumined by the false glamour which attaches to the remaining parts of the paper, in which, *inter alia*, he suggests that there is probably at least a germ of truth in what has been claimed for the Chassagne process, viz., selective colour absorption. If Mr. Hitchcock had taken the trouble to acquaint himself with his subject, he would have known that the Chassagne process was utterly and finally discredited in Great

Britain more than eighteen months ago, and that not a soul in this country who knows anything of the subject now believes that it is anything but a simple and easily acquired process of colouring albumen prints by hand with aniline colours and a mordant. There are other erroneous passages in Mr. Hitchcock's paper, which we need not quote; but we have extracted more than enough from that unfortunate composition to show that the author can scarcely be accepted as a reliable guide on colour photography. Fancy a self-constituted authority on such a subject saying that "why one thing is blue, another red, is inexplicable!" What were the authorities of the American Association about when they accepted such a paper? And surely there are men in that body who would refuse to swallow Mr. Hitchcock's amazing dictum that, because a photographer observed colours on a developed transparency plate, therefore "this is nothing else than photography in colours." Breathes there the photographer with sight so dim who has not seen phenomena of the kind which he has been powerless to produce a second time? Before Mr. Hitchcock makes a further contribution to the literature of colour photography, we advise him to master an article on "Colour Photography" in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1899 by the Editor of that volume. He will find it of use in preventing the commission of blunders the like of which we hold it impossible to excuse in a man of his undoubted intelligence.

---

**Chloride of Gold.**—As was seen by our report, last week, of the Photographic Club, complaint was made that the commercial chloride of gold was not so good as the home-made salt. That is frequently the case, but there is commercial chloride of gold and commercial chloride of gold. Some of the chloride in the market, if it contained the theoretical quantity of gold, would entail a considerable loss on its vendors. But there is chloride of gold in the market, each tube of which bears a label guaranteeing that it contains so many grains of the metal; these brands may be relied upon as containing that amount. But they necessarily cost more than the salt just referred to, though they are much cheaper in the end. One of the members at the Club meeting expressed the idea that more gold was recoverable from acetate and borax baths than from sulphocyanide baths, although there might be the same amount present. That, of course, is a fallacy, for whatever gold there is in a bath it may be recovered, quite regardless of the composition of the bath, if the proper means of doing so be taken. But it is obvious that, if all the gold has been used up in toning prints, there is none to be recovered from the exhausted solutions.

---

**Separation of Mixtures of Chloride, Iodide, and Bromide of Silver.**—M. H. Baubigny, in a communication to the Paris Academy of Sciences, confirms his previous results in this direction—the employment of oxidising agents to detect the presence of bromine in the above mixture. The wet magma of the silver haloids is treated with nitric acid and crystals of permanganate of potassium. This transforms the iodide into iodate, and does not sensibly act on silver chloride, while the bromide is attacked very slightly. The merest trace of bromide vapour can be detected by fluoresceine paper, which is extremely sensitive to bromine.

---

**Photographs of High-voltage Sparks through Air.**

—Those who are interested in the study of lightning-flash photographs will find in *Nature*, of February 9, some remarkable photographs of electric sparks from a battery of 10,000 elements, giving, approximately, 20,000 volts, and with a further modification giving a voltage of 3,000,000, the spark in air being from 6½ to 7 feet in length.

We have photographs of sparks exactly like lightning flashes and of one passing over the surface of water. Dry plates, in ordinary dark slides, held from 6 to 10 feet away from the terminal, are acted on, and developed with arborescent figures. One single spark, occupying an instant of time, passing through a Crookes' tube, will give a Röntgen-ray picture of a hand, but the tube is destroyed in the process.

**A Promised Revolution in Electric Lighting.**—We have on former occasions referred to the entirely new form of electric light invented by a young German scientist, Professor Nernst. Those who were fortunate enough to be present at a recent meeting of the Society of Arts had presented to them, by Mr. Swinburne, a masterly exposition of the theory of electric and other incandescent lighting, with practical illustrations of Professor Nernst's invention. At the conclusion of his remarks, Mr. Swinburne said: "It is difficult to discuss an invention like this without being carried away by enthusiasm. I feel, however, that I have but feebly shown forth the probable future of what seems to me the greatest invention in electric lighting that we have known for many years. Still, I am sure I have not been too sanguine." There is no doubt that the publicity and *clat* given to the invention by a lecture before the Society of Arts will so make it known that, if it possess anything like the merit claimed for it, we shall indeed see a revolution; and so simple is the new lamp that we may expect to see electric lighting in the studio the rule instead of the exception it now is. The simplicity of the whole thing is so striking that the chief wonder about it is that no one thought of it before. An infusible refractory earth is made into a rod, and being under ordinary conditions an insulator, electricity will not pass through it; by heating it with, for example, a lighted match or a spirit lamp, it at once becomes a conductor, and the resistance it offers to the current brings it to a state of brilliant incandescence, rivalling the electric arc and completely putting into the shade the ordinary incandescent carbon filament of the now common incandescent lamp. Already experimental lamps have been successfully worked for 500 hours, and it is anticipated that eventually the life of a lamp may be prolonged almost indefinitely. A familiar note was struck in the discussion by Mr. W. M. Moodey, who, in congratulating Professor Nernst upon his invention, said they must take care he had the credit of it, and "was not robbed by a number of people who would immediately be writing to the *Times* to say they had done the same thing in their back kitchen twenty years ago. This was what always took place in the case of a new invention." Photographic inventors know this to their cost; indeed, there could scarcely be named a business or profession making use of new inventions which so many inventors had been robbed of their ideas, which had laid the foundations of others' fortunes.

**Bequerel's Rays.**—In the *Revue Générale des Sciences* for the 30th ult. is a paper by Madame S. Curie upon her investigations upon the radiating body, supposed to be a new element, which she has separated, as before described by us, from pitchblende. Uranium and, largely, the new element, polonium, together with many other metals and their salts, emit, without being previously exposed to light, radiations possessing many properties in common with X rays. They pass through, virtually, all substances—glass, paper, metals, liquids. But their most remarkable property is their continuity of action without further apparent excitation. They thus in appearance seem to controvert the law of conservation of energy, and as the radiations emitted are capable of doing work, the problem of perpetual motion would appear to be actually solved, for no proof is offered that the actual substance of the emitting or radiating body suffers diminution of weight by emission of particles of its own substance. Finally, it may be noted that, while uranium, hitherto the most powerful radiating substance known, requires one hour's action to produce photographic effects, polonium needs only three minutes, though it is to be remembered that Madame Curie has extracted from polonium another substance whose photographic action is as much stronger than that of polonium as the latter's is stronger than uranium.

**Photography and Politics.**—It is said "they do things better in France." Perhaps they do, though that may be open to question in some matters. It is said that a packet of 5000 photographs of the Duke of Orleans has been seized on the French frontier. This reads somewhat strange to our English ideas, and we naturally feel some little curiosity to know upon what grounds such simple things as photographs of an individual have been seized. So far as we are aware, there is no law in this country that prohibits the importation of portraits of any person, whether he be an enemy of the State or not; but evidently, if the report be correct, the law is different across the Channel.

By the way, referring to France and its customs, the Paris correspondent of the *Standard*, telegraphing one day last week, says that considerable interest is being taken in art circles in a forthcoming sale of three pictures left in the hands of the French authorities as security for 91,000 francs. As considerable doubt existed as to their authors, experts have been called in to examine them, and they have come to the conclusion that one is the work of Claude Lorraine, the second by Greuze, while the third is signed on the back "A. V. D. Werf." If these pictures are genuine, as the experts say, the French authorities hold very good security for the money they advanced.

**Scientific Ballooning.**—In concluding a paper he read at a Society last week on "The Balloon as an Instrument of Scientific Research," the Rev. John M. Bacon expressed the opinion that, with properly designed spectroscopic and telescopic cameras, it was reasonable to hope that, at high elevations, they might penetrate with greater success than heretofore into the ultra-violet of the spectrum, and, even under conditions of diminished air glare, photograph the sun's corona without an eclipse. If that could be accomplished, it would be a great scientific achievement, and of great value. Solar eclipses are few and far between, and long and costly expeditions have to be made to make observations; but, if much that is then accomplished, supposing the weather proves favourable, can be done by a balloon journey of 20,000 or 30,000 feet in a balloon, it would be a great acquisition to science.

#### ON A SIMPLE METHOD OF DETERMINING THE FOCAL LENGTH OF A COMPOUND LENS.

In the course of some writing I am at present engaged upon I have had occasion to consider this question from "J. F. T.'s" very reasonable standpoint, and give below the simplest method I can think of "from the practical point of view of the working photographer." It does not necessitate special apparatus, although a true measure, and not an approximation, in its theoretical aspect.

1. Reverse the lens in its flange on the camera, and focus accurately upon a distant object (condition for parallel rays). Measure the distance from some definite point in the mounting of the lens, the hood, for instance, to the plane of the ground glass. (This gives the distance between the hood and the front "focal plane" of the compound lens.) Say it is nine inches.

2. Screw the lens in the flange in its ordinary position, and again focus accurately upon a distant object (parallel rays). Mark its position upon the baseboard of the camera. (The focussing screen now lies in the plane of the back focal point.)

3. Now proceed to focus accurately upon a near object placed at a distance of three or four times the (roughly estimated) focal length of the lens from the hood of the lens, say fifty-nine inches. The focussing screen will have to be racked out from its position for parallel rays (as in 2) a certain distance. Measure this; say it is two inches.

We know that the distance of the object is 59 inches, less 9 inches (as in 1), from the front focal plane of the compound lens, and that the image is 2 inches from the back focal plane.

$$\begin{aligned} \text{Hence } F^2 &= 50 \times 2 = 100; \\ \text{or the focal length} &= \sqrt{100} \\ &= 10 \text{ inches.} \end{aligned}$$

This method will be found to involve less labour, and is less liable to

error, than either of the methods given by "J. F. T." (I believe the credit of the second method he gives is due to Grubb.)

The knowledge of the true focal length of a lens alone is of little practical value to the photographer, but the knowledge of its focal length in conjunction with the distance of the front focal point or plane from some definite point of the lens itself will be extremely useful for accurate proportions in reduction or enlargement.

*Example.*—A reduction of four times is required with the lens in question. It is only necessary to place the object four times the focal length of the lens away from the front focal point or plane of the lens, or  $4 \times 10 + 9 = 49$  inches from the hood, when a certain reduction of four times is at once arrived at upon accurate focussing.

*Note.*—The positions of the focal points of a positive-lens system never alter. Once found, they are always known.

T. R. DALLMEYER, F.R.A.S.

### COLOUR-SENSITISING PLATES.

DR. G. EBERHARD, of Gotha, reports the results of his further researches on the use of the artificial colouring matters for sensitising plates in the current number of the *Photographische Correspondenz*.

Comparative exposures were made on an ordinary plate and one sensitised with Diazo black BHN, according to Valenta's formula. In most cases a preliminary ammonia bath was used, and the plates bathed for three minutes.

#### 1. SOCIÉTÉ CHIMIQUE DES USINES DU RHÔNE (GILLIARD, MONNET, & Co.).

*Noir de Lyon.*—None, or faint continuous sensitising; blue extremely strong.

*Cyclamin.*—This dye is, according to Schulze (*Tabellerische Uebersicht* No. 362), a fluoresceine derivative, and proved to be a very vigorous sensitiser, which might with advantage be used instead of rose Bengal or rose Bengal double, as the action reaches rather further into the orange. The silver precipitate is very vigorous. In a weak bath of dye 1:500 0.5 and water 100, there appeared a vigorous band  $C_3D-D_3F$ , with the maximum at  $D_3E$ . A minimum lay at  $Eb$ . Blue is more vigorous than orange-yellow and yellow. With greater concentration (water, 100; dye, 10; ammonia, 2; silver nitrate, 1:50 1), the band stretched from  $C_3D$  to  $E$ , falling slowly towards  $E$ . The maximum was at  $D$ , the orange yellow was stronger than blue, and the sensitiveness was good.

#### 2. JOH. CONR. REIHLEN IN FRIEDENSAU IN DER PFALZ.

*Nigrosin R wasserl.*† gives even with a weak bath (water, 100; 0.1 dye, 1:500), a narrow, vigorous band,  $C_3D$  to  $C_3D$ , and a weaker one  $D_3E-D_3E$ . With stronger concentration, the first band was more intense but not broad, and the second was weaker. The action extended from  $A$  right into the ultra-violet, and continuous from  $A-C$ . The blue was always very strong.

*Nigrosin R wasserl.*—The appearances are analogous to the above dye, but the second band ( $D-E$ ) is broad, and the action, with a weak bath and short exposure, extends to  $A$ . With strong bath, the regions  $A-a$  and  $B-C$  stood out as weak maxima in the continuous action.

*Nigrosin R and B spiritl.* were not tried.

#### 3. KINZLEBERGER & Co., IN PRAG.

*Alizarin gelb G*, weak action, falling quickly towards  $D$ .

*Glycinroth*, flat and weak band to  $C$ , with maximum  $D-D_3E$ .

*Glycinblau*, flat and weak band to  $B$ , with maximum at  $D$ .

*Glycinorinth* is a good sensitiser, which is important for practical work. It gives with very short exposure a continuous band to  $C$ , with longer to  $B$ ; slight maximum at  $Eb-Eb_3F$ . The region  $C-D$  is, with an exposure of half a second, as vigorous as a Diazoschwarz BHN plate with five seconds' exposure. The following formula is good:—

Water .....	100 parts.
Dye solution (1:500 in alcohol and water) ...	3-5 "
Ammonia .....	2 "

Herr Valenta has informed me privately that his experiments with this dye were unsuccessful, so further researches will be made.

#### 4. BINDSCHEDLER & Co., IN BASEL.

*Rhodamin 10 G*, a very vigorous band  $D-E$ , with maximum  $D_3E$ , and this would be of value were it not surpassed by erythrosine.

\* In all cases the names of the dyes are given as in the original paper to avoid possible errors in description.—TRANSLATOR.

† Wasserl. and spiritl. are abbreviations for wasserlöslich and spiritlöslich, or water and spirit soluble.

#### 5. GESELLSCHAFT FÜR CHEMISCHE INDUSTRIE, IN BASEL.

*Chitonblau B*, with great concentration and not too short an exposure, a vigorous band  $B-C_3D$ , and a very narrow weak band at  $D$ .

*Säureviolett 4 R*, with great concentration and long exposure a very faint band  $D-Eb$ , maximum  $D_3E$ .

*Säureviolett 7 B*, vigorous band  $C-C_3D$ , maximum  $C_3D$ , with long exposure; also a continuous action from  $B$  to  $E$ , with narrow and weak minimum about  $D$ , the principal band stood out very prominently. A strong bath is necessary.

*Karbidischwarz B* gives a band  $a-E$  falling towards  $E$ , maximum  $C-B$ ; acts weaker than Diazoschwarz BHN.

*Karbidischwarz BO* extraordinarily vigorous sensitiser. The best bath is

Water .....	100
Dye (1:500) .....	0.1
Ammonia .....	2

The band begins at  $A$ ,  $A-B$  weak, from  $B-E$  very strong, maximum  $C-B$ , slowly falling towards  $E$ . This dye acts about five times stronger than Diazoschwarz BHN, and it ought to be of great practical value, as the plates have good sensitiveness, are free from fog, and develop dense.

#### 6. SCHUCHARDT IN GÜRLITZ.

*Toluylenroth*, weak band  $C_3D-E$ , maximum  $D_3E$ .

*Toluylenblau*, a very difficult dye to use, as the least trace of alkali in the plate destroyed it. With a weak bath and silver nitrate a very narrow and weak band about  $a$ . The sensitiveness considerably lowered.

#### 7. K. OEHLEH IN OFFENBACH.

*Toluylen gelb*, *Toluylenorange G*, *Toluylenbraun OO*, *Toluylenbraun Q*. all give weak continuous action towards  $D$ .

*Toluylenorange R* and *Toluylenorange RR* give a weak band,  $D-E$ , the maximum of which is not very distinct, less about the middle.

*Toluylen schwarzblau B*, vigorous band,  $C-D$ , with long exposure beginning at  $B$ , also a weak band,  $D-E$ . The action is almost as good as Diazoschwarz.

*Toluylen schwarzblau B*, vigorous band,  $B-D$ , with long exposure beginning at  $a$ , and a weaker band from  $D$  to almost  $E$ . A good formula is:—

Water .....	100
Dye (1:500) .....	4
Ammonia .....	2

The action is better than Diazoschwarz.

*Neutoluylenblau B*, with strong concentration and moderately long exposure, a fairly strong band,  $B-C$ . With moderate concentration there appears a weaker band,  $C_3D-D$ . The dye does not act at all when weak.

*Naphtazurin R*, band,  $C-D$ , with long exposure,  $a-D$ .

*Naphtazurin BB*, very vigorous, band,  $a-D$ , with maximum,  $B-C$ , even with very short exposures. With longer exposure the action begins at  $A$ . A good formula is—

Water .....	100
Dye (1:500) .....	2
Ammonia .....	2

*Azochwarzblau B*, fairly vigorous band,  $B-D$ , falling quickly towards  $E$ .

*Azocorinth*, none or faint sensitising towards  $D$ .

*Azomaue B*, vigorous band from  $B$ ; maximum,  $C-C_3D$ ; minimum,  $D_3E-E$ . A good formula is:—

Water .....	100
Dye (1:500) .....	3-5
Ammonia .....	2

The action is stronger than Diazoschwarz.

### A PLEA FOR PYRO IN THE DEVELOPMENT OF LANTERN SLIDES.

WERE it possible to obtain the opinions of the great bulk of amateur workers regarding the most suitable developer to employ in the case of lantern slides, printed by means of any of the various brands of lantern plates now upon the market, it is just about ten to one that such would display a decided preponderance in favour of hydroquinone over all the other reducing agents which from time to time are advocated for this special class of work. No doubt the great popularity which hydroquinone has attained for this class of work lies in its cleanliness and freedom from any liability to stain the film, even after a fairly long time in development, and no doubt these two points are matters of considerable importance with amateur workers, who, on the other hand, look with

horror upon the idea of attempting to produce anything approaching such cleanly results with the aid of pyro and soda, or pyro and ammonia.

Here, in the West of Scotland, at least, for lantern-slide development, hydroquinone is very largely used; but there are, on the other hand, several of the more knowing ones who firmly pin their faith to pyro, and will not allow anything to tempt them from their first love.

During the last two seasons Glasgow has without doubt led the van in the matter of limelight lecturing, and first, with something like a series of thirty-six lectures, or one nightly over a period of six weeks, during the run of the 1897 Exhibition, when nearly every limelight lecturer of note in the United Kingdom was engaged at the Fine Art Institute, and which was followed, in 1898, by another full series of lectures under the auspices of the Messrs. Lizars. Glasgow photographers, both amateur and professional, may be said to have had more than usual facilities for judging of the various lecture sets that were put through the lantern during the run of these important functions, and it can be said that in Glasgow, where there are so many expert amateur slide-makers, a considerable amount of interest was shown in the various samples of slides that each lecturer used, as well as the further opportunity that was afforded the public of seeing the display of members' work furnished by our various local societies.

In the latter instance, the slides of one gentleman in particular stood out in a very marked manner from the great majority supplied by other workers, and, on minute investigation being made into the reason why such slides showed such a distinct superiority over the others, it was ascertained that not only the charming colour, but likewise the lovely range of tones, from high lights to transparent shadows, were produced by means of good old pyro and soda in some instances, with that of pyro and ammonia in others. That this should not have left its mark upon the workers of the West of Scotland would have been strange indeed, especially seeing so much rivalry exists in the matter of lantern-slide making, and so, during the last few months, in Glasgow at least, a decided reaction has set in in favour of pyro, the hardness and crudeness of hydroquinone-developed slides, with the, generally speaking, coldness of tone in the same, caused many to turn their attention towards producing the lovely black-brown so much admired in the case of the pyro slide.

There is no doubt that the one great stumbling-block in the use of pyro for lantern-slide development lies in the liability of staining the film, for all who use pyro for this purpose are not possessed of the knowledge requisite to use the same so that any discolouration should not take place, and some workers have been known to argue that to use pyro without a stain was impossible of accomplishment.

The fact, however, remains, that pyro can be so used, and is daily so, by myself and several others in the West of Scotland, made to produce slides absolutely free from any stain or discolouration. This use of pyro is easily accomplished by the exercise of a few well-recognised facts in this class of work. What these requirements are may be briefly stated as extreme cleanliness and a very carefully compounded formula in development.

In using pyro for this work, any one that has been accustomed to employ hydroquinone is very liable to fall into the error of trying to make a certain quantity of solution do duty for more than one slide, thereby using a solution that has become more or less oxidised before the same has been applied to the plate; therefore such workers ought, at the very outset, to discard all the routine applicable to hydroquinone, and use pyro as it will only allow of being used, viz., a new and fresh solution for each plate or batch of plates. In saying this much, however, it must be understood that the formula used in the development of lantern slides requires to be most carefully compounded. Doubtless there are several excellent formulae, both with soda and ammonia, now before the public, any of which, if carefully used, are capable of working cleanly enough; but in my practice I have never come across any formula to equal that which I believe was first recommended by Mr. J. Leisk, now over ten years ago, and I can, with the utmost confidence, recommend any ardent lantern-slide maker to adopt the same, with the utmost certainty of producing slides delightful in colour, range of tones, and absolute freedom from stain.

This developer is prepared as follows (and there must be no guess-work in doing it):—

First, a ten per cent. pyro stock solution is made up as under: Make a saturated solution of sulphite of soda in distilled water into each ounce of which 6 grains of citric acid have been previously dissolved; then to 9½ ounces of this saturated solution add 480 grains pyro (each 10 minims should then contain one grain).

Call the above A solution, or No. 1, or any other symbol, to show it is pyro. Then dissolve 4 ounces of carbonate of soda, 288 grains of pure sulphite of soda, 40 grains of bromide of ammonium, in 32 ounces of water.

Call this B, or soda solution, and, when going to develop, prepare the following clearing bath: Add two drachms of strong acetic acid to one pint of water. Pour one half of this into a basin, in which place a soft sponge or tuft of cotton-wool, and place the other half into a developing tray.

To develop, add from 20 to 60 drops or minims of pyro to each ounce of soda solution, and pour over the plate in the usual manner.

When the image appears, lift frequently out of the developer and examine for density, making allowance for a certain amount of loss in fixing. The image should be well seen at the back of the plate. When development is finished, sponge the slide gently, but rapidly, with the clearing bath in the basin, then place for a few minutes in the tray containing the other half of the acetic acid solution. Afterwards, well wash under the tap and fix in newly mixed and unused hypo.

It is claimed that, by working in the above manner, any one solution may be made to develop a number of plates in succession without yielding any stain, but such is not the result of my experience. Forcing in development is to be avoided, and the best way to prevent such is of course to give the utmost attention to a correct exposure that just meets this formula in development.

In using the pyro judgment must, of course, be exercised according to the nature of the subject to be developed, i.e., some subjects require more pyro than others; but, if this developer is carefully compounded and used as recommended by Mr. Leisk, there will be no staining the film, and slides will be produced which no hydroquinone formula ever could equal.

As compounded in separate solutions, the pyro and soda keep admirably, or without deterioration, for a considerable time.

It will be found that different makers' plates require varying quantities of pyro to gain density, but the old advice of sticking to one brand of plates will overcome any liability to get far wrong in the gaining of density, for it must be borne in mind that as much harm is done from over-density as from under.

I can confidently recommend the above method of lantern-slide development to the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY.

T. N. ARMSTRONG.

#### THE LATEST COLOUR PHOTOGRAPHY PROCESS.

This is due to the International Colour Photo Company, of New Jersey, whose English agent thus describes it:—

In making my improvements in the art of producing coloured pictures by the aid of photography, I take paper, opaque white celluloid, or other similar material suitable for the purpose, and upon its face rule separate fine alternate lines of such dyes or colours as to correspond substantially with the fundamental colours of the spectrum, say, reddish-orange, yellowish-green, and violet-blue, in the order of the spectrum, or upon the face of which I place small alternate dots, squares, or figures in any manner sufficiently close to present to the eye a neutral surface. The colour of each dye is preferably of such depth as to absorb the kind of light transmitted by the others. More than three colours in the dots, or lines, or figures, may be used, such as the complementary colours, red and green, blue and yellow, or the whole series of the spectrum. Such a mixture of colours placed side by side follows the laws of the mixture of lights and not of pigments.

After the paper or similar material has been provided with its proper colours, as above explained, it may be covered with a coating of gelatine and with a sensitising material such as is used in sensitising the paper now used for photographic purposes, so that the lines, figures, or patterns of colours will be covered with the sensitising material. If desired, however, the paper may be first sensitised and the lines or patterns of colour or dyes afterwards applied. After being thus prepared, it forms what is ordinarily called printing paper adapted to be printed upon either through a negative, or by the use of metal or glass half-tone plate in a press with printer's ink. It is intended to be used where the negative is produced by the use of a transparent screen arranged in the camera before the sensitised surface of a dry plate, which screen, it will be understood, must, of course, be provided with lines, dots, squares, figures, or patterns corresponding to those on the printing paper, which causes the negative to be impressed with similar lines, figures, or patterns, and in printing from it the paper must first be placed upon it in such position that its lines, figures, and patterns register with similar lines, figures, and patterns on the negative.

For the purpose of printing on a mechanical press, I make a photographic screen, say, such a one as is ruled or printed in the alternated lines above, one hundred to the inch of each colour, or three hundred to the inch of all, one coloured line to transmit reddish-orange, the next yellowish-green, the next violet-blue, and so on in alternation; or, in other words, colours approximating to the recognised fundamental colours of the spectrum. The negative made in the use of this screen will be in lines, opaque where the coloured light has been transmitted and transparent where it has been absorbed. From this negative I make a metal or glass half-tone plate by any of the usual methods. This half-tone plate is divided on its surface by these manipulations in alternate raised lines, each corresponding to the amount of colour absorbed by the coloured lines of the screen or plate in the camera; or, in other words, to the non-action of light on the sensitised photographic plate, the depressions corresponding in width to the amount of light affecting the sensitised plate of the negative. A print taken from this half-tone plate upon white paper will show, with black ink, a lined black-and-white picture, or, where dots and figures are used, it will show a black-and-white picture corresponding to the pattern.

In order to print a coloured picture, I take a sheet of the printing paper, prepared as above described, containing the coloured lines, dots, figures, or patterns corresponding to the screen and negative, and to which the half-tone printing plate also corresponds in register, and print upon it, by means of the half-tone plate, a black or dark ink, making it register, so that the black ink will cover to its proper degree the colours which were absorbed in the camera by the coloured plate or screen, and leave uncovered or exposed those colours whose corresponding colours in the object to be photographed have impressed themselves on the negative in the camera. The blacks are formed by the black ink, the whites by the combination of the coloured lines, dots, or figures not covered by the ink, and the intermediate mixture of colours by the combination of such coloured lines, dots, figures, or patterns as are not entirely covered or obscured.

Fig. 1 represents the invention when embodied on a paper having parallel alternating different lines.

Fig. 2 represents the same when the paper is provided with alternating lines of coloured dots.

Fig. 3 represents the same when the paper is provided with the seven

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

primary colours of the spectrum recurring in their regular order of sequence.

Fig. 4 represents the same as fig. 3, with the addition of the transverse black lines.

Fig. 5 represents the same when the paper is provided with alternating red and blue lines crossed transversely with yellow lines forming with the red, at the intersection, orange dots, or squares, and, with the blue, green dots or squares.

Fig. 6 represents the same as fig. 1, except that the lines are rounded in waving or curved order.

Fig. 7 represents the same when the paper is provided with a different

Fig. 5.

Fig. 6.

Fig. 8.

Fig. 7.

arrangement of dots or squares from that shown in fig. 2; and

Fig. 8 represents the same when the paper is provided with alternating zigzag lines of different colours.

The claims made for the process are:—

1. A white or light-coloured material, as paper, bearing a pattern symmetrical as to a plane in the primary or approximately primary colours used, and in such dyes or pigments as have suitable selective light-absorption properties.

2. A white or light-coloured material, as paper, provided with coloured substances arranged according to regular recurring patterns of such

colours as to cause each to absorb such colours as are transmitted by each and all the others.

3. A white or light-coloured material, as paper, provided with red, green, and blue-coloured substances arranged according to regular recurring patterns, symmetrical as to a plane, such colours being of such kinds and in such proportions as to present to the eye a white or neutral tint.

4. A white or light-coloured material, as paper, provided with red, green, and blue-coloured substances arranged according to regularly recurring patterns in regular recurring alternate order and symmetrical as to a plane, such colours being of such kinds and in such proportions as to present to the eye a white or light-coloured neutral tint, the patterns being covered with a photographic sensitive material.

5. A white or light-coloured material, as paper, provided with differently coloured substances corresponding to complementary colours of the spectrum, as red and green, blue and yellow, arranged according to regular recurring patterns, as dots, lines, figures, in regular recurring alternate order and symmetrical as to a plane, such colours being of such kinds and in such proportions as to present to the eye a white or light-coloured neutral tint, the patterns being covered with a photographic sensitive material.

6. The process of making coloured pictures, which consists in making a photographic negative in regular patterns, as dots, lines, figures, by the action of red, green, and blue-coloured lights upon the sensitive plate in such patterns, then making therefrom a corresponding half-tone plate, printing type or surface, then printing from such printing surface upon material prepared to correspond in colours and to register in form and dimensions with the patterns of coloured lights acting upon the negative and with the patterns upon the printing surface, whereby the colours corresponding to those that do not act upon the negative will be obscured or covered, while such proportion of coloured patterns as corresponds to the action of coloured lights upon the negative sensitised plate will be left visible.

7. The process of making coloured pictures, which consists in printing upon a material prepared to correspond in colours and register in form and dimensions with the patterns of red, green, and blue-coloured lights acting upon a negative, whereby the colours corresponding to those that do not act upon the negative will be obscured or covered, while such proportion of coloured patterns as corresponds to the action of the coloured lights upon the negative sensitised plate will be left visible.

8. The process of making coloured pictures, which consists in covering or obscuring by means of a positive picture the colours upon a material prepared to correspond in colour and to register in form and dimensions with the patterns of red, green, and blue-coloured lights acting upon a negative, whereby the colours corresponding to those that do not act upon the negative will be obscured or covered, while such proportion of the coloured patterns as corresponds to the action of coloured lights upon the negative sensitised plate will be left visible.

## RETOUCHING WITH A PIN.

It is the great ambition of photographic apprentices to be able to retouch, and in many establishments every encouragement is given.

Some make rapid progress, others fool away their time, and are as far forward at the end of their term as at the beginning. One bright youth, who was allowed an hour daily for practice, kept pegging away for months without progress. He was constantly bending over the retouching desk with no practical results.

Occasionally a march was stolen on him, and suspicion became very strong that, instead of working his pencil, he was indulging in numerous forty winks. He became so expert at napping while in an attitude of working, that ways and means were discussed to confirm or dispel the suspicion.

A happy thought came—to remove the pencil from the holder and substitute a piece of sharpened metal.

Time went on; for weeks that apprentice went through the formula of practising retouching, utterly oblivious of the change in pencil.

When at last his idleness was brought home to him, he stoutly maintained he had been retouching, and was not the sleeping beauty proved.

This event, of some years ago, recurred to my mind the other day, with the result that I took an ordinary pointed pin and tried to retouch with it. Strange to say, instead of scratching the film and ruining the negative, the marks were of a similar nature to those of an extra-hard, sharp-pointed lead pencil.

Subsequent trials have produced very satisfactory results.

The retouching can be done direct on the gelatine film, but is altered to an extent when varnished. So in practice it is preferable to varnish first and then retouch.

The pin works remarkably well on ordinary hard negative varnish. The pin pencil costs nothing, is always sharp, with a finer point than any other, especially valuable in softening deep, fine wrinkles. No medium is required, and it is absolutely free from grit.

By filing off the head of pin it can be pierced into a holder, and will prove a useful addition to the retoucher's pencils, if not a complete substitute.

THOMAS M. LAWS.

## A METHOD OF TONING WITH URANIUM.

VARIOUS salts of uranium in connexion with ferriocyanide of potassium (the red prussiate of potassa) act more or less as toners, says Mr. G. Gibson in the *American Journal of Photography*, but the persulphate of uranium gives the most satisfaction.

Make a ten per cent. solution of ferriocyanide of potassium; also a ten per cent. solution of persulphate of uranium.

For use, dilute with equal bulk of water for albumen prints, or four times as much water for aristo paper prints.

The mixture should be of a clear reddish-brown colour. The action is rather rapid, especially if the solution is used too strong, and it is best to start with a weak bath. The tones obtainable are brown, chocolate, purple brown, purple, and plain black if the action is carried on.

Too far toning gives unpleasant slaty black colours. There is scarcely any danger of stain or of double toning. When used too strong at first, the tone is liable to incline to foxy red. One peculiarity of this toning method is, it must be applied to fixed prints thoroughly washed.

After printing to the desired depth wash the prints as usual, fix (for aristos in weak hypo solution), then thoroughly wash. Insufficient washing will not cause stain, but the print will reduce in the subsequent toning and have a faded appearance. Toning unfixed prints with uranium did not give me any good results.

This toning solution is adaptable to transparencies and lantern slides, giving the same range of tones, but it should be used quite strong—almost the ten per cent. solution.

The tones on paper prints are pleasing; but whether lasting I cannot say, as I have only employed the method for little over a month.

## THE RESTORATION OF DAGUERRETYPES.

PROBABLY one of the most beautiful and, at the same time, most permanent of photographic processes, so far as the resulting pictures were concerned, was the old Daguerreotype. The process, however, was an expensive and a lengthy one, and, in consequence, had to give way to glass positives, which, in turn, were superseded by the modern pictures on paper, ivory, or porcelain. There are probably very few of the old workers of the Daguerreotype process left amongst us, but their works are still surviving. Scarcely a family among the upper and upper middle classes of society but possess one or more specimens of Daguerreotype, representing members of their family or dear friends who have in all probability long since passed to that bourne from which no traveller ever returns. These relics have in some cases been so carefully treasured and cared for that they are still as clear and bright as when first turned out from the producer's hand, while in other instances they have become dulled and indistinct owing to the oxidising influence of the atmosphere, which has been unwittingly allowed to act upon them, either from the hermetic sealing having been imperfectly executed or having become broken away, thus exposing the metallic plate to the full influence of the air. Photographers, both in this country and abroad, are constantly being asked to restore these faded relics, and but very few either attempt or, if the truth be told, know how to do so.

The Daguerreotype is a very delicate thing to handle; but, if care be taken, it is not a difficult matter to restore a merely faded one to the whole of its pristine beauty and clearness. When I say merely faded, I mean that the plate has not been in any way interfered with by unskilled hands, for, if such has been the case, if, say, some one has taken off the protecting glass, and rubbed the picture even with a silk handkerchief, the difficulty of restoration is not only increased, but very likely restoration rendered an impossibility. The picture is, in point of fact, a most delicate film on the surface of the silver, and, being unvarnished, is susceptible of injury from any rubbing or abrasion, however gently it may be done. Again, the picture may have already been in the hands of some other restorer (?), who may have attempted the work by some method other than the correct one, and may consequently have left some trace of a chemical behind that would impede or totally destroy any chance of genuine restoration. The first thing to do before undertaking an order is to ascertain that you are the first person into whose hands the work of restoration has been given, then to take off the glass and examine that the film be unbroken by scratches. If such be the case, the work may be undertaken with confidence, and is proceeded with in the following manner: Immerse the plate in a one per cent. solution of cyanide of potassium in distilled water, and carefully rock the dish until the milky or smoky appearance caused by oxidation disappears. If the strength of the cyanide does not have the desired effect, it may be increased, but care must be taken to use pure distilled water, and to touch the film with nothing whatever; even cotton-wool would cause scratches. So soon as the oxidation is removed, wash well in several changes of water, still noting that ordinary tap or rain water will not do; it must be distilled, if the work is to be properly executed.

When washed, dry by gentle heat in an atmosphere as free from dust as possible, as any dust settling on the picture cannot be brushed off without serious risk or damage. When dry, you will be able to see

whether anything further is required; in nine cases out of ten it will be found that the picture is already to all intents and purposes restored, although in the tenth it will be found that it is still lacking in detail and brilliance. In such a case redeveloping has to be resorted to; this process requires very careful manipulation, but can be successfully carried out by any one possessing a fuming box such as used for fuming albumenised paper. This, I may mention, is a box standing at least three feet from the ground, and nearly as air-tight as possible. On the bottom of the box place a small spirit lamp, and over the lamp a small saucer of mercury (the metal not bichloride). Affix the Daguerreotype face downwards to the lid of the box and close up for two minutes; then examine the plate and continue to do so at intervals of about a minute until all detail is up. Then remove the plate, put out the lamp, and close up your fuming box. During this operation the greatest care should be taken that none of the fumes of mercury be inhaled, as they are most poisonous. Lay a piece of clear, clean glass, plate if possible on the Daguerreotype and bind the edges with silk, using a plentiful supply of Canada balsam to stick the silk and keep the Daguerreotype from air.

The process of redeveloping, I must repeat, requires the greatest care in manipulation owing to the extremely poisonous nature of the fumes, and should never be resorted to by any one when the cyanide process brings up the image sufficiently. C. BRANWIN BARNES.

## TONING AND MODIFYING PRINTS AFTER DEVELOPMENT.

At the Photographic Club, on February 15 (Beginners' Night), Mr. Thomas Bedding in the chair, Mr. W. Ethelbert Henry gave a lecture upon the above subject.

He supposed that all beginners at some time or other had trouble with their prints, and it was the usual thing that defective prints, such as he passed round, were consigned to the waste receptacle. It was with a wish to avoid this waste that he proposed to demonstrate a few practical expedients for improving in one way or another the unsatisfactory results which even an established man is liable to produce; and, although these expedients did not claim to be new, the fact that they were not largely employed was sufficient in his opinion to warrant his bringing them again into notice.

It very often occurs that, in attempting to secure a decent red tone by direct development, one succeeds in making a print of a nasty brownish colour. There are formulae published which claim to give the desired tone, but, in the case of the print to be operated upon, this end was sought by increasing the exposure and by certain modifications of the development. Much might be done by way of improving this brown print by toning with gold and sulphocyanide and a black or purplish black colour substituted for the undesirable tint. The following bath is recommended:—

Ammonium sulphocyanide .....	20 grains.
Gold chloride .....	1 grain.
Water .....	2 ounces.

Before applying this to the print the latter should be damped. The action is rapid, three or four seconds sufficing to carry the tone verging on blue. The print should be washed for some fifteen or twenty minutes.

In the case of a print of a cold tone by direct development, to which we wish to impart a warm brown colour, the following course may be followed: The print is bleached in mercuric chloride 120 grains to 8 ounces of water, to which are added 2 drachms of hydrochloric acid. This solution is applied to the damp print, and the action, which is very quick, may be stopped by immersing in water and washing thoroughly. The bleached print is then blackened in a one per cent. solution of hyposulphite of soda, which gives rich brown blacks tending to sepia according to time of immersion.

Mr. Henry then showed another type of print of common occurrence, one showing a very heavy appearance, due to over-exposure and over-development. Supposing that we belong not to the class who look upon such things as excellent pictorial results, we, doubtless, wish to reduce the density, and not only on the high lights, but as a whole. Such a print would well be negotiated by subjecting it first to a one per cent. solution of persulphate of ammonium. The effect of this treatment is to attack the heavy deposit of silver, and, when this is judged to have proceeded sufficiently far, the print is rinsed and immersed in a second bath compounded as follows: A saturated solution of iodine in alcohol, and a saturated solution of potassium cyanide in water are required. A few drops of the first are taken, and, to this a few drops of the cyanide are added, in excess, until the discolouration is dispersed. Diluting the mixture, we complete the reduction of the print. The double process constitutes to a great extent a selective reducing action. An over-exposed and over-developed photograph of the moon was next treated. Contrast was wanting, and in this case the print was reduced generally by the iodine and cyanide formula, very weak, and, to make up for the deficiency of deposit in the shadows, toned in gold and sulphocyanide, the resulting colour being very appropriate, and the print of a much richer appearance.

The following formula was given as a means of imparting to prints a blue tone:—

Ammonio-citrate of iron (ten per cent.) .....	5 parts.
Potassium ferricyanide (ten per cent.) .....	5 "
Nitric acid (ten per cent.) .....	10 "
Water .....	100 "

After a few moments a pleasing black tone results, but continued immersion gives to the print a decidedly blue tone. This may be intensified by treatment with a solution of cyanide of potassium (1 in 5000), which also clears the whites and brightens up the whole image. Simple washing of the print, however, will effect this purpose. The method is particularly applicable to transparencies and lantern slides, and a specimen of the kind was shown.

Pleasing red tones were to be obtained by the use of a formula composed of the following salts in ten per cent. solutions:—

A.	
Water .....	20 parts.
Copper sulphate .....	1 part.
Ammonium carbonate .....	(about) 8 parts.

A thick precipitate is formed on mixing the ingredients, which redissolve on adding sufficient of the carbonate, leaving a clear solution. In another vessel are mixed—

B.	
Potassium ferricyanide (ten per cent.) .....	25 parts.
Water .....	150 "

The copper solution is then added to the contents of the second vessel, and a turbid solution results, which will render a fine red colour in a short space of time.

It frequently occurs that vignettied bromide prints are far from satisfactory, the vignetting being abrupt and harsh. An improved appearance may be given by treatment in the following manner: After damping the print and removing the surface liquid, a strong solution of the iodine and cyanide bath described above is applied with a piece of cotton-wool, the print being supported on a sheet of glass, and the parts which are not required gently gone over with the solution. Having cleared away superfluous deposit at the edges, the vignetting is softened down by holding the print under a tap, and while the water plays upon the centre dabbing the parts with the strong solution. To remove any possible fog on the print, the strong solution remaining may be diluted, and the whole of the print immersed for a few seconds. In the event of a flat dense print being under treatment, the general density will be reduced, and pluck may be given by toning with gold as described. A print which, at first, was very far from satisfactory was handled in the above manner, and the improved appearance was very marked.

The above are a few practical dodges which may often serve good purpose; but, as Mr. Henry said, they in no way exhaust the list. For the most part, waste Velox prints were those used to demonstrate upon, with a few ordinary bromide prints thrown in.

#### STALE PLATES IN LANTERN-SLIDE MAKING.

In the production of lantern slides by means of gelatino-chloride plates there is no doubt old or stale plates never produce such bright, sparkling results as are obtainable by means of newly coated samples.

Among amateur workers especially there is a strong chance when purchasing an odd box or two of any well-known brand, that what is acquired may have lain upon the dealer's shelves for a considerable length of time, there being no data placed upon the boxes or labels whereby any one can ascertain the date of coating such plates, the public cannot be guided as to whether such are stale or fresh.

As a rule, one of the first indications of a plate having been coated for a considerable length of time is observed when the development stage is reached, for around the edges of the plate there will be apparent a decided lack of lustre, verging almost to a discolouration, from the presence of chemical fog, and a distinct appearance of insensitiveness around the sides of the plate.

Plates stored in unsuitable positions in a dealer's store do not take long to reach such a stage of deterioration, and in winter time, when a low temperature is prevalent in the developing room, it is next to impossible to develop such plates without the results showing a very marked degree of opalescence in those parts that ought to show up as absolutely clear glass.

In such subjects as black-and-white objects this becomes a serious matter, for it is most annoying to produce these opalescent results, and, although the better course to follow is undoubtedly to discard all such stale plates, still at times fresh plates are not at hand, and the best must just be done with what are available. It is well known that the application of a coating of suitable varnish is in some cases a ready means of getting rid of this opalescent appearance, and conferring a bright and sparkling appearance to such a result. But then, again, many workers have a distinct objection to the application of varnish to their slides, by

reason of the almost certainty of introducing a crop of slug markings and other undesirable eyesores, which otherwise would never put in an appearance.

The fact is, the varnishing of lantern slides is a more delicate operation than many amateurs imagine or care to undertake, although in reality an operation quite successfully performed when any one makes a practice of doing such under proper conditions, such as not over-heating the plate, and studiously warring against that arch enemy dust.

There is, however, luckily, another very easy method whereby such an opalescent appearance can be removed without having recourse to the messy operation of varnishing, and this treatment is so exceedingly simple that any one can resort to it with the greatest ease.

When a lantern slide, after being fixed and washed, shows this undesirable appearance, let the same be immersed for a second or two in lukewarm water, and it will be found that the opalescence will disappear as if by magic, and not afterwards put in an appearance when the slide is finally dried.

One of the earliest formulæ for the development of some special make of lantern plates was that of pyro and ammonia used in conjunction with bromide of ammonium as a restrainer, and there is no doubt that, properly used on fresh plates, this developer is capable of yielding the most lovely slides imaginable; but, whenever a plate is being treated that has passed into the stale stage, it is almost next to impossible to obtain any result other than such containing chemical fog, which, in lantern slides, ought never to appear. This fog, very probably, may also show as a metallic deposit on the surface of the plate, and the moment it begins to appear so soon does all detail cease to develop up further, and in negative work this is bad enough, but in a lantern slide it becomes absolutely destructive. Such plates may be caused to yield better results by discarding pyro and ammonia for one or other of the developers, such as pyro and soda, or any good hydroquinone formula; but such can never be made to yield such bright and sparkling results as a freshly coated plate.

It cannot be said, however, that the dealers are responsible wholly for the supplying of stale plates. Amateurs themselves have a bad trick of keeping a stock of plates beside them for an indefinite period, and such are not long in suffering deterioration if stood in any damp or unsuitable place.

A. T. NEWTON.

#### AT THE CAMERA CLUB.

MANY very interesting lectures have been given at the Camera Club during the past week or two; but, as the subjects have not been of a photographic character, we have been unable to give them the attention they would otherwise deserve. The energetic Hon. Secretary, Mr. Godfrey, must at least be congratulated upon the varied fare which he has been enabled to place before the members, and by the large attendances secured it is evident that he works in a direction which is approved.

Perhaps the most technical of the recent papers was that by the Earl of Rosse on the heat of the moon, which, of course, gave an opening for the exhibition of photographs, those dealing with the varied phases of an eclipse being especially interesting. It has possibly not occurred to ordinary mortals that the moon has any heat, and although the poets of all times have been fond of describing her pallid beams, they have been silent on the question of heat. Perhaps we should except the poetical incident with regard to Endymion, when chaste Luna certainly did exhibit some amount of warmth. But Lord Rosse made no allusion to that pretty story, but contented himself with dry facts. By means of a powerful reflecting telescope, with smaller condensing mirrors to throw the rays upon a thermopile it has been found possible to ascertain that the moon gives off a perceptible amount of heat. When an eclipse occurs, back goes the needle of the galvanometer, and, strange to say, it does not recover its former position for hours after the moon regains its brilliancy. This was the most noticeable feature of Lord Rosse's paper, and one for which there is at present no satisfactory explanation.

A discourse of a very different character was that delivered on the 16th inst. by Dr. Gray, who has had the unique experience of living for a long time at Kabul, under the immediate protective friendship of the Ameer of Afghanistan. Dr. Gray carried a camera with him and was thus able to illustrate his remarks with plenty of interesting pictures, and, as he had ventured into regions where no camera had been carried before his photographs were the more valuable. Those familiar with the past history of our dealings with Afghanistan were glad enough to see actual photographs of such places as the Kyber Pass, the Fort of Ali Musjid, Jellalabad, &c., and a glance at them, with the terrible events they recalled, enabled one to understand the name given to their inhospitable country by the natives—"The land of stones and blood."

Dr. Gray made his way to Afghanistan by invitation of the Ameer. As a matter of fact, no one can get to Kabul except under that condition, and the approaches are so difficult that the regulation is not easy to circumvent. On his road thither he went *via* Peshawur, and met a guard of horsemen sent by the Ameer to escort him to Kabul. Many pictures of the rocky Kyber Pass showed the barrenness of the land through which the traveller went, and one or two of these pictures

showed the nature of the so-called villages—in reality forts with towers at their corners. From Jellalabad to Kabul was a continual ascent, through rocky gorges and pebbly valleys.

At one point the traveller saw in the distance what he took to be a flagstaff, but it turned out to be a high post with an iron cage at the top, which had a gloomy history. It seems that at one time highway robbery was common on this road, but at last one of the men was caught red-handed, and his punishment consisted in being shut up in this cage to die of starvation. This very thorough method of dealing with the offender had the effect of stopping robberies completely on that particular road.

A view of Kabul, with its 60,000 inhabitants, and of the Lahore Gate, through which the traveller entered it, brought Dr. Gray to the beginning of his exciting experiences at the court of the Ameer.

When Dr. Gray arrived, the Ameer was absent in Turkestan, and the Doctor was received by one of the princes, and welcomed to the country. But the interview was cut short by the occurrence of an earthquake, which the superstitious prince regarded as a sign of Almighty displeasure.

Many photographs were shown of the inhabitants, and it was noteworthy that the peasants carried a curious spade with a bar above the blade to accommodate the naked foot in the act of digging. At court, a semi-military European dress was commonly worn, the Ameer priding himself on adopting western customs, and looking upon himself as a most advanced monarch in that respect. Dr. Gray found that the art of medicine in Kabul was in a most primitive state, and much suffering and fatal results were brought about by the ignorance of the native doctors. By adopting European methods and remedies he quickly checked the high death rate which had previously prevailed, and, when the Ameer saw that the English mode of treatment produced good results on inferior beings, he condescended to intrust his own sacred person to Dr. Gray's good offices.

Upon examination the Ameer was found to have a complication of diseases, the most aggressive of which was gout. His state was not improved by the native remedies—chiefly bleeding, and, putting the feet into ice-cold water. However, under sensible treatment, he quickly recovered, and showed many signs of gratitude to his new doctor.

Dr. Gray's entertaining reminiscences were interspersed with little humorous touches which were much appreciated by the large audience which had assembled to listen to his most interesting lecture.

#### PHOTOGRAPHING OLD LONDON.

UNDER the Chairmanship of Sir J. Benjamin Stone, M.P., who, as President of the National Photographic Record Association, has already done great public service by securing for preservation at the British Museum so many photographs of present and future historical interest, a meeting was held on Tuesday last, February 21, for the purpose of discussing the possibilities and best methods of securing photographic records of ancient and decaying buildings in and around London. Among those present were Mr. B. L. Cohen, M.P., Sir H. Trueman Wood, Messrs. George Scamell, and J. W. Marchant, Dr. H. R. Mill, Mr. George Ashbee, Colonel J. Waterhouse, Mr. Thomas Bedding, F.R.P.S., Mr. B. E. Lawrence, Mr. Frank Haes, Mr. W. B. Stretton, Mr. W. A. J. Heneler, Mr. A. Kemp, and many representatives of antiquarian, archaeological, architectural, and photographic societies.

In a brief introductory address the Chairman pointed out that the work which amateur and professional photographers were willing to undertake in securing photographs of old buildings was very frequently useless without antiquarian assistance, and he thought that archaeologists and antiquarians might therefore be of very great help to photographers in scheduling and particularising the interesting places that should be photographed. Having referred to the success which was attending the Warwickshire Photographic Survey scheme, due to the systematic subdivision of the work, Sir Benjamin considered that London might be treated in a somewhat similar manner. The various archaeological societies might combine and prepare a list of the photographs to be taken. At the same time a small fund might be collected for purchasing photographs, or prints from the negatives, in the hands of professionals, who could hardly be expected to part with them for nothing. He also said that individual photographers might be of great assistance in the scheme by contributing photographs of old or disappearing parts of London, and concluded by pointing out that, as many of the old London landmarks were rapidly disappearing and constant changes were going on in the metropolis, there was an urgent necessity for securing photographic records of them without delay.

In the informal discussion that followed Sir Benjamin's address several suggestions were made. One was to the effect that the manner in which archaeological surveys of counties were conducted afforded a guide to the way in which a photographic survey of old London could be carried out. Dr. H. R. Mill emphasised the necessity of photographing old buildings before they were taken down, and new buildings as they were put up. Mr. George Ashbee (representing the Survey of Greater London) said there was a great deal of overlapping amongst the various societies doing survey work. He suggested that an exchange of prints might take place between them to their mutual advantage.

After other remarks from gentlemen representing the City of London and the City of Westminster, who said that the authorities of those places would be happy to co-operate with those anxious to secure photographic records of objects of historical interest, it was agreed, on the motion of the Chairman, that a committee should be appointed to carry out the objects of the meeting and settle details of procedure. This having been agreed to, a vote of thanks was passed to the Chairman on the proposition of Sir H. Trueman Wood.

#### EXHIBITION OF THE WEST LONDON PHOTOGRAPHIC SOCIETY.

THE West London Photographic Society held its Tenth Annual Exhibition of members' work on Friday and Saturday, the 17th and 18th inst., at the Broadway Lecture Hall, Hammersmith, W.

The Exhibition of this Society is always well worth a visit on account of the sterling good quality of the work that is to be found there. The hall, which forms the gallery, is not an ideal one for a picture exhibition, and very little seems to have been done to overcome its natural defects by even simple methods of decoration. The hanging of the pictures, at any rate, in the present case, has been performed in a way that would hardly commend itself to the new school of critics in exhibition management; but, in spite of these minor shortcomings, any of the exhibitions in recent years would have afforded a pleasant hour's recreation to any one content to study the pictures themselves, without regard to their surroundings. We must say, however, that in some matters of detail the arrangements have been improved, much to the comfort of visitors. The lighting in the evening was much better, indeed beyond reproach, and the system was adopted of hanging each exhibitor's works together, and the pictures were plainly labelled with the title and author.

We cannot say that we noticed any very marked improvement in the quality of the work over last year's. The average is perhaps better, but the prominent members of the Society have long since passed the stage when their work improves by leaps and bounds. Harry Selby, Leslie Selby, G. Lamley, A. E. Cockerell, M. W. Cockerell, and G. F. Blackmore fully maintain the reputation they have earned, and, with such leaders to work under, the junior members of the Society should have no difficulty in coping with the ordinary troubles of beginners, both in the technical and pictorial sides of photography. Mr. Blackmore showed, we think, the only examples of "gum-bichromate," but they were not an unqualified success. Mr. W. Collith, who has not exhibited before, struck the most original note in the Exhibition. His choice of subjects showed an appreciation of what is requisite to make a picture; but it was in his technique that he scored. His prints appeared to be on unusually rough bromide paper, rubbed down after the prints were made with some abrading material, so as to leave the whole broken up, much as we find it in an ordinary gum-bichromate print on rough paper.

We do not say that was the process employed, nor can we say that it was equally successful in all his pictures. In the best subject the effect seemed rather overdone. The paper employed was too coarse in the grain. We cannot help remarking on the singular unsuitability of the frames and mounts this gentleman chose, and this was the more noticeable, that by far the largest proportion of the pictures in the Exhibition were admirably got up. Other exhibitors who deserve a word were J. Brown, W. Taylor, and Miss F. Marion. The last-mentioned goes in for a variety of subjects of an interesting rather than a pictorial nature. There were all kinds of curious things that, for a little want of skill in the printing, her exhibit would have been an admirable one of its kind.

Many of our exhibitions suffer from a too exclusive devotion to landscape work, and that under review is one of them. We would suggest to the members that there are other branches of photography—portraiture, figure studies, and architecture, for instance—which are well worthy of their attention. The Society having abolished awards there were no judges.

#### PHOTOGRAPHIC PAPER AND THE AMERICAN PAPER TRUST.

THE subjoined article, contributed by Mr. C. T. Sutton, to THE BRITISH JOURNAL OF PHOTOGRAPHY,\* should be interesting to American photographers just now, says *Wilson's Photographic Magazine*. For weeks little else has had attention except the changes in the printing-paper market, caused by the advance in the price of raw paper made abroad and almost universally used in this country.

Without being too sanguine, we believe that the action of the European Paper Trust is calculated to result in good for our country. The paper used for photographic purposes in America should be made in America, and nothing could be imagined so likely to bring about this desirable state of affairs as the stand taken by the manufacturers forming the Paper Trust. We have many mills here capable, were their enthusiasm aroused, of manufacturing photographic papers equal to the best made in Europe. The American Photographic Paper Company (of Boston), the Valley Paper Company (of Holyoke), and the Holyoke Paper Company, and other mills have been producing excellent paper for photographic use for some years. Their papers have been coated and sensitised, and have stood the tests required of them. The reasons why they have not

\* January 6, 1899, p. 10.

been more generally used by manufacturers of printing papers are, as far as we can discover: First, a preference for foreign-made papers as having an established reputation; and, second, that the coating of American-made papers with baryta has not always resulted as successfully as might be desired. These minor difficulties will, we trust, be speedily overcome, and, in a year or two, we look forward to a steady decline in the importation of European papers for use in photography. If our paper-manufacturers, producers of sensitised papers, and photographers unite in the desire to make and use American paper in place of that imported, we have little doubt but that the thing can be accomplished.

### THE LATE F. P. WRATTEN.

A CAREER which gave every promise of materially contributing to the advancement of scientific photography was ended on Saturday week, February 11, by the death of Mr. F. P. Wratten. The deceased gentleman, who was in the twenty-fifth year of his age, was the second son of Mr. F. C. L. Wratten, the respected head of the well-known firm of Wratten & Wainwright, dry-plate makers, Croydon. Becoming a student of chemistry at an early age, he soon acquired the degree of Associate of the Royal College of Science, and for several years occupied himself in the laboratory and emulsion department of Messrs. Wratten's manufactory. He took great interest in the preparation of high-speed emulsions, and, after several months' absence in America in the year 1897, returned to this country for the purpose of devoting himself to research work in orthochromatism. There is little doubt that the heavy strain imposed upon him by the close attention which he gave to this absorbing branch of experimental photography was the direct cause of the mental illness which led to his death. By training, inclination, and intelligence, the late Frederick Percy Wratten gave the greatest promise of one day occupying a high and honourable place in scientific photography, and we are sure that regret at the premature close of his life will be accompanied by wide and sincere sympathy with his family in their bereavement.

## Our Editorial Table.

### HINTON'S SQUEEGEEING AND MOUNTING BOARD.

Manufactured by Hinton & Co., 38, Bedford-street, Strand, W.C.

THIS useful piece of apparatus consists of a strong flat board, to which are attached, in such a manner as to be easily removable, several sheets of tough fibrous blotting boards, protected by a cover of strong rubber sheeting. To use for squeegeeing the sheets of ferrotype, celluloid, glass, or other material, bearing the prints to be squeegeed, are placed between the blotting boards and both hands used to squeegee on the rubber protecting sheet, the latter taking all the strain and drag, and the prints being subjected to a very even pressure. If ferrotype or celluloid is used, several sheets of prints may be squeegeed at once between the separate sheets, the top one being removed after each stroke of the squeegee.

For mounting, the print, having been pasted as usual, is centered on the mount and laid on the blotting boards, directly under the rubber sheet, and the squeegee passed over first lightly and again with more pressure. For the rapid drying of prints the latter should be immersed in a bath of methylated spirits until the backs show a uniform semi-transparent appearance. They are then drained and laid in single layers between the blotting boards and heavily squeegeed. We can recommend this squeegeeing and mounting board to both professional and amateur photographers, who should find it of the greatest utility in squeegeeing, mounting, and drying prints. It is extremely well made and cheap.

### THE PRIMUS PRINTING FRAME.

Manufactured by W. Butcher & Son, Blackheath, S.E.

THESE printing frames are neatly made, cheap, and useful. They are made in stout wood without any projections, so that when packed away they occupy the least space. The springs are sunk, and, instead of

slipping under the ordinary projecting metal catch, they are passed into a groove in the frame. They are machine-made, and consequently perfectly true everywhere. The Primus frames are comfortable to handle, and will, doubtless, be appreciated by many photographers.

### A NEW CAMERA SCREW.

Manufactured by H. Renbold, 5, Jeffreys-road, Clapham, S.W.

THE screw and bolt as here illustrated are let into the bottom of the hand or stand camera. It thus forms a permanent part of the instrument to which it is fitted, and consequently does away with the risk of loss of the ordinary screw. Saving of time is claimed through the instantaneous fitting of the bolt on to the screw instead of, so to speak,

working about in the dark, trying to find the bush in the camera. In the case of a stand camera, this latter operation generally results in the scratching of the polished baseboard round and about the bush. The illustration shows the nature of the improvement, which should be greatly appreciated by all users of cameras, as it economises both time and temper, and prevents the loss of an indispensable item in camera work.

### SPECIMENS OF VELOX PRINTING.

By R. C. MURRAY, Garrick-street, Covent Garden.

AMONG those early to recognise the advantages of Velox for printing from amateurs' negatives was Mr. Murray, whose ability and experience in all branches of photography need no encomium at our hands. Mr. Murray has submitted to us a number of prints on Velox paper, which are among the very finest of the kind we have seen, and some of which make it clear that the paper in skilful hands gives a considerable amount of latitude—a quality much to be desired when amateurs' negatives are being dealt with. As a careful and painstaking photographic printer Mr. Murray is worthy of the highest recommendation.

THE London and Blackfriars Photographic Supply Company, of 134, Borough, S.E., have been good enough to send us one of Messrs. Charles Letts & Co.'s very thin Peerless Pocket Note-books, which has a self-indexing memorandum tablet attached to the under cover, thus enabling any "place" in the little book to be retained. But the most acceptable feature of the note-book is a Railway Accident Insurance Coupon for 500l., available up to March 31, 1900. We have no doubt that some hundreds of these little books will quickly find their way into photographers' pockets. They measure 4 x 2½ inches, and are handy to have in a railway collision.

The Company propose presenting one of these note-books to any customer placing an order with them to the amount of 5l. net, from Feb. 16 to April 30.

## BIRABROOL.

Sole Agent: OSCAR SCHOLZIG, 9, New Broad-street, E.C.

THIS is a solution for enabling the amateur to make his own sensitised paper, sensitised view post cards, or pictorial letter headings. The following are the instructions:—Spread the liquid with a camel's-hair brush—which must be free from any metal parts—thinly over the part of the paper which is to receive the picture, and dry it for a few minutes in the dark. When dry, place it in the printing frame under the negative, and by sunlight you will get a fully printed picture in seven to fifteen minutes. When fully printed, put the picture for one minute into the fixing bath—50 grains sulphite of soda, 50 grains hyposulphite of soda, 5 ounces of water—wash in clean water for five to ten minutes, and dry.

MESSRS. A. & M. ZIMMERMANN, of 9 and 10, St. Mary-at-Hill, E.C., send us samples of the fixing salts manufactured by the Actien Gesellschaft für Anilin-Fabrikation, Berlin. This preparation is packed in four, eight, and sixteen-ounce blocks, which simply require dissolving in eight times their weight of water to give an acid fixing bath, of the strength necessary for negatives. It is then ready for immediate use. The samples reached us in the form of a very fine white powder, which, upon trial, was found to give a clean and excellent fixing bath.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, March 1, at eight o'clock, lecture by Mr. Sydney Keith, "Up the Nile."

MR. J. EPSTEIN has been awarded a diploma at the Grahamstown Exhibition, South Africa, for his show of mouldings, mounts, &c.

MR. A. E. ALLEN, Hon. Secretary of the South London Photographic Society, has removed to "Beaulieu," Hollingbourne-road, Herne Hill, S.W.

ROYAL PHOTOGRAPHIC SOCIETY.—Tuesday, February 28, Technical Meeting. "Apparatus for Animated Photography," by Mr. Birt Acres. To be held at 12, Hanover-square, W., at eight p.m.

On Thursday, February 16, at the Goldsmiths' Institute, there were 1500 persons present at Mr. Bynoe's lecture on "The Camera and the Wheel." This is believed to be a record audience.

THE AUSTIN-EDWARDS MONTHLY FILM NEGATIVE COMPETITION.—The prize camera for the current month has been awarded to Mr. Charles R. Taunton, care of Mrs. North, Springfield-avenue, Huddersfield, for his negative, *Among the Hazels in the Hollows*.

THE names of the prize-winners in the Warwick Monthly Competition for February are:—1st prize, 20s., Mr. T. Knox, Charlotte-villa, Sydenham, Belfast; 2nd prize, 10s., Mr. Frank M. Sutcliffe, 12, Skinner-street, Whitley; 3rd prize, 5s., Mr. W. B. Green, Gramere, Gladstone-road, Watford, Herts.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday next, March 2, at eight o'clock, Mr. J. McIntosh will read a paper on "Intensification and Reduction," with illustrations. The Hon. Secretary will be pleased to see any one interested in the subject at this meeting. Visitors are always welcome.

OCCASIONAL LECTURES AT BEDFORD COLLEGE.—The first of the series will be given by Dr. W. J. Russell, F.R.S., Chairman of the Council, on Friday, February 24, at five p.m., at Bedford College, York-place, Baker-street, W. Subject: "How Pictures can be taken on a Photographic Plate in the Dark," with lantern illustrations.

EXTREMELY ANCIENT MIRRORS.—At one of the recent sessions of the French Academy Berthelot described three metal-backed glass mirrors of great antiquity which had been originally discovered in Thrace and Egypt. The metal backing of these mirrors consists of almost pure lead, which, in the molten state, appears to have been poured on the concave surface of discs cut from balloons of blown glass. This appears to be a highly important contribution to the history of the arts among the ancients.

BROKEN glass, usually considered one of the most worthless of things, promises to become an article of commerce in some parts of the world. In Switzerland and France the manufacture of glass brick for paving purposes has just been taken up on a large scale, and Geneva already enjoys the distinction of possessing several glass-paved streets. The new material looks well, and gives a safe footing for horses. Nice also will have a glass pavement in the near future. The glass scrap is first heated until soft, when it is compressed into bricks. By this treatment the glass loses its transparency, but its strength and power of resistance to shock and fracture are increased. Glass scrap has hitherto been converted into ornamental tiles.

CONSIDERABLY over two hundred ladies and gentlemen attended the Fourth Annual Smoking Concert of Mr. J. Fallowfield's employees, which was held on Friday evening, February 17, at the London Tavern, Fenchurch-street, E.C. Mr. F. W. Hindley occupied the chair, and among the visitors were Mr. Hindley, jun., Mr. Thomas Bedding, Mr. A. E. Dean, Mr. J. A. Sinclair, Mr. R. Child Bayley, Mr. S. H. Fry, and Mr. A. Mackie. Mr. H. J. White was in the vice-chair, and Mr. F. J. Goode was, as hitherto, a hard-working and vigilant Hon. Secretary, and under his direction a long and amusing programme of songs, recitations, and other items was carried through. During the evening the thanks of the company were tendered to the Chairman and the Hon. Secretary, and the entertainment concluded amidst the manifestations of pleasure of those present. All concerned are to be congratulated on a great success.

CROYDON CAMERA CLUB.—The meeting on Wednesday, February 15, was devoted to a lantern lecture upon "Hand-camera Work," read by the President on behalf of Mr. J. H. Gear. This was followed by the inspection of a large number of lantern slides by the members. At the instance of the President, seconded by Councillor J. Noaks, it was resolved "that the Hon. Secretary be instructed to convey the Club's sincere sympathy with Mr. Wratten and family at their bereavement."

NITRATE OF SILVER STAINS.—A solution of iodine in ammonia water, the so-called colourless tincture, will remove nitrate of silver stains from the hands, clothing, &c., but owing to the danger of the formation of nitrogen iodide, which is a very powerful explosive, it is not recommended. A solution of iodine in iodide of potassium dissolved in water is nearly as quick, and quite as effective. Dissolve 15 parts of iodide of potassium in 50 parts of water, and to the solution add 10 parts of iodine. When the latter is dissolved, add sufficient water to make 500 parts. Keep in a well-stoppered bottle. Treat the spots with this, and after a few minutes with a ten per cent. solution of caustic soda, which will remove the silver iodide formed by the first treatment.—*National Druggist*.

THE Beverley Photographic and Sketching Society's Sixth Annual Public Exhibition of Photographs, Paintings, and Drawings will be held in the Assembly Rooms, Beverley, on Easter Monday and Tuesday, April 3 and 4, 1899. The following are the photographic classes:—Section A. (open): 1, Landscape, Seascape, and River Scenery; 2, Architecture; 3, Portraiture and Figure Studies; 4, Instantaneous Hand-camera Work, showing Moving Objects (six direct prints); 5, Enlargements; 6, Lantern Slides (set of six). Section B (members only): 1, Landscape, Seascape, Architecture, and River Scenery; 2, Portraiture and Figure Studies; 3, Enlargements; 4, Lantern Slides (set of six, the winning sets to become the property of the Society). The Hon. Secretary is Mr. T. J. Morley, Toll Gavel, Beverley.

NEW USES FOR GLASS.—Experiments have lately been made with glass as a substitute for metals for bearings. The most suitable kinds were found to be bottle and ordinary window glass. The bearings were cast in moulds, in two pieces. They gave the best results when mounted in elastic supports. It was found to be necessary that the revolving parts should be well balanced and the shafts accurately centered. The results are stated to have been that the glass bearings require less lubrication, have less friction, and in many cases are more advantageous than metal bearings, though in some cases they afford less security than others. It is recorded in the French journal, *L'Edairage Electrique*, that at Marseilles glass tubes are being used as underground conduits for telegraph wires and for carrying electric-light wires in factories, theatres, &c.

NORTHAMPTON EXHIBITION.—The following are the Judges' awards in the open classes:—Champion Class: Silver medal (No. 19), *Sunlight and Shade*, by Mr. F. W. Bannister; bronze (No. 5), *The Storm Lifting*, by Mr. C. F. Inston. Portraiture, Genre Studies and Animals: Silver (No. 68), *Portrait*, by Mr. Smedley Aston; No. 86, *Portrait*, *Christopher Wilson, Esq.*, by Miss Boden. Architecture: Silver (No. 251), *Ely*, by Mr. C. S. Baynton; bronze (No. 224), *Lincoln Interiors*, by Mr. John H. Gash. Hand-camera Work: Silver (No. 275), *The Olive-gatherer*, by Dr. E. G. Boon; bronze (No. 265), *Series* by Mr. W. E. Inston. Landscape, Seascape, and River: Silver (No. 306), *End of a Winter's Day*, by Mr. W. A. Fraser; bronze (No. 296), *Evening on the Chase*, by Mr. W. Smedley Aston. Lantern Slides: Silver, Mr. E. Marriage; bronze, Mr. C. M. Wane.

IRON FELT.—This is the name given to a new insulating substance made at the Adlershof Works, near Berlin, and for which numerous applications have been found. The felt consists essentially of long and strong woollen fibres, impregnated with a by-product of petroleum, and then coated (with a certain amount of penetration) by gelatine rendered insoluble, and also (alternatively or in addition) with indiarubber, afterwards vulcanised. After being subjected to considerable pressure, the iron felt assumes the form of plates, measuring 20 sq. dm. (2 sq. ft. 22 sq. in.) and upwards, with a thickness varying from 1 to 5 centimetres (13-32 in. to 2 in.). These plates are very elastic, being practically imperishable, while they will stand a pressure of 1458 kilogrms. per sq. cm. (20,736 lbs. per sq. in.); and their surface is so hard as not to be cut by the sharp edges of bolt heads or of iron girders. Placed as a cushion between rails and their chairs, or sleepers, underneath plumper-blocks or between engines and their foundations, this substance is also stated, by *La Nature*, to prevent vibration.

THE BIRMINGHAM INDUSTRIAL EXHIBITION.—The Photographic Section of this Exhibition bids fair to be a very large one, and Mr. Welford, who has it in charge, informs us that he is surprised at the great number of applications for prospectuses, which have been arriving by post at the rate of eighty per week, after 4000 preliminary copies were dispatched to all well-known

exhibitors. In a former issue we referred to the fact that the medals offered would be of a design differing from those as usually given, and above we are able to give an illustration of it. The wording will, of course, be altered. The Exhibition will be opened on Monday, March 20, by the Lord Mayor of Birmingham, and Mr. Welford will endeavour to post a printed list of awards to every competitor on that night.

**PERMANENT INK FOR GLASS AND METAL WARE.**—The following inks are suitable for labelling and otherwise marking glass or metal ware. The marks are not washed off by water. Black: Fluid Indian ink, 11 parts; sodium silicate, 1 to 2 parts. White: Chinese white or barium sulphate, 1 part; sodium silicate, 3 to 4 parts. This ink must be kept in stoppered bottles and well shaken up before use. The writing is done with a steel pen. When dry the ink is affected by very few reagents, but can easily be scraped off with a penknife. The strength of the sodium silicate is not given, but probably the ordinary commercial thirty-three per cent. solution is referred to. The colours are to be well dried and finely powdered before being used.—*Pharm. Zeit.*, 43, 860, after *Deutsch. Mech. Zeit.*

## Patent News.

The following applications for Patents were made between February 6 and February 11, 1899:—

**CINEMATOGRAPHS.**—No. 2630. "Improvements in or relating to Cinematographs." H. MORRISON.

**DEVELOPERS.**—No. 2756. "Improvements in Photographic Developers." Communicated by The Chemische Fabrik auf Actien vormals E. Schering, Germany. A. ZIMMERMANN.

**ANIMATED PHOTOGRAPHS.**—No. 2840. "Improvements in Apparatus for Displaying Animated and other Pictures, Advertisements, and the like." W. A. SEYMOUR.

**LENSES.**—No. 2854. "Improvements in Photographic Objectives." Complete specification. C. P. GOEZE and E. VON HOEGH.

**PHOTOGRAPH-CARRIERS OR STANDS.**—No. 2908. "Improvements in Carriers or Stands for Photographs and the like." J. CADBURY and F. W. LAMBERT.

**ANIMATED PHOTOGRAPHY.**—No. 2954. "Improved Means applicable for use in taking Photographic Views in Rapid Succession or in presenting the same in like manner." C. RALPH.

**LENSES.**—No. 3041. "Improvements in Photographic Objectives." Complete specification. E. LEITZ.

**COATING PAPER FILMS, &c.**—No. 3086. "Improvements in the Method, Means, and Apparatus for Coating Photographic Paper, Films, and the like, and in the Manufacture of Photographic Materials." J. E. THORNTON and C. F. S. ROTHWELL.

**VIGNETTING APPARATUS.**—No. 3129. "Improvements in and connected with Photographic Vignetting Apparatus." C. S. SOUTHIN.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

February.	Name of Society.	Subject.
27.....	Beverley	Prize Slides.
27-Mar. 4	Birmingham Photo. Society	Annual Exhibition.
27.....	Bradford Photo. Society	Some Analogies of Light. Edgar A. Heywood.
27.....	Camera Club	Art Enamels. Cyril Davenport, S.S.A.
27.....	Kingston-on-Thames	Hand-camera Work. John H. Gear.
27.....	Oxford Camera Club	Home Portraiture. Miss Acland.
27.....	Richmond	Lecture: Practical Points in Exposure, Developing, and Printing.
28.....	Hackney	Annual Dinner.
28.....	Leeds Photo. Society	Colour and its Reproduction by Photography. E. J. Wall.
28.....	Newcastle-on-Tyne	Demonstration: Photogravure. Messrs. Corder and Spence.
28.....	Royal Photographic Society	Apparatus for Animated Photography. Birt Acres.
28.....	Shropshire	Invitation Exhibition of Members' Slides.
March.		
1.....	Brentford	Lantern Evening.
1.....	Croydon Camera Club	Fortieth Public Lan'ern Show.—A Visit to Penshurst Palace. D. P. Roberts.
1.....	Leeds Camera Club	Paper by A. Horsley Hinton.
1.....	Photographic Club	Up the Nile. Sydney Keith.
1.....	Southsea	Photographic Chemistry. H. T. Lilley, M.A.
1.....	Woodford	Some Notes on Photographic Chemicals. Mr. Emier.
2.....	Ashton-under-Lyne	Sale of Monthly Magazines.
2.....	Bolton Mutual Photo. Society	Our Trip to Spain. N. S. Kay.
2.....	Leigh	Highways and Byways in Venetia. S. L. Coulthart.
2.....	Liverpool Amateur	Demonstration: Carbon and Gum-bichromate. Jos. Appleby.
2.....	London and Provincial	Intensification and Reduction. J. McIntosh.
3.....	Croydon Microscopical	Meeting to Arrange for Summer Excursions.
3.....	West London	Holiday Rambles. W. A. Brown.
4-11.....	South London	Tenth Annual Exhibition.

### ROYAL PHOTOGRAPHIC SOCIETY.

FEBRUARY 21.—Photo-mechanical Meeting.—Mr. Chapman Jones, F.I.C., F.C.S., in the chair.

#### OFFICERS AND COUNCIL.

The CHAIRMAN announced that the Council had made the following appointments:—*Hon. Secretary*, Colonel J. Waterhouse; *Hon. Librarian*, Mr. Horace

Wilmer, C.E.; *Hon. Solicitor*, Mr. Francis Ince; *Hon. Editor of the Society's "Journal"*, Captain W. de W. Abney; and that they had elected Messrs. J. A. Hodges and J. J. Vezey to fill the vacancies thus occasioned among the ordinary members of the Council.

### PHOTOGRAPHY OF LIGHTNING IN DAYLIGHT.

Mr. F. H. GLEW gave a "Demonstration with Wireless Electric Waves for Actuating Photographic Apparatus and for Photographing Lightning in Daylight," illustrating a most interesting and comprehensive lecture upon the subject. Commencing with a consideration of the analogy between lightning sparks and sparks produced in the laboratory, the difference in the conditions, and the effects of the temperature and pressure, he proceeded to deal with the various types of sparks and the oscillation and periodicity of the disruptive discharge, pointing out that, whilst the sparks from a coil result from a very sudden rise of potential, lightning probably results from a somewhat more gradual rise of potential, increasing until bursting point is reached, caused by the union of particles of water, a condensation of electricity being thereby produced. In attempting to photograph lightning flashes at night in the usual manner, he had been surprised at the large proportion of failures he had had, many plates being entirely blank, although he was quite sure that the camera was correctly placed in the line of sight. He had thought that this was probably caused by the extreme vividness of the lightning producing reversal; but he found that he got better results with the lens working at  $f/8$  than at  $f/16$ , and also that a rapid plate, preferably with a double or triple coating, was an advantage. The next point considered was the question of the duration of the lightning flash, which had been estimated variously from millionths of a second to 1-10,000 of a second; but the lecturer had ascertained that these estimates were not borne out by his own recent photographic measurements by using a lens made to vibrate at a known rate, or by means of a photographic plate in motion. One of his experiments showed that with a lightning spark of three components the entire flash lasted  $\frac{1}{10}$  of a second, the time between one component and another being about  $\frac{1}{100}$  of a second, and he thought this experiment demonstrated the fact, that the lightning flash was compound in character and had a perceptible duration. The lecturer next dealt with the compound nature of lightning, not one spark but several passing down the same path, the radiation of Hertz waves during a lightning discharge, and demonstrated an apparatus which he described as a Hertzian sentinel, for giving warning of an approaching storm; and he then proceeded to discuss the nature of Hertz waves, their detection by a scraping spark gap, and the action of the coherer detector, and to analyse the Hertz waves, dealing with syntony and "skin" currents. Photography of lightning in daylight, he said, had been attempted, and difficulty arose in consequence of the fogging of so many plates, and it had been noticed that the flashes thus obtained were dark instead of light, a reversed effect; but Mr. Clayden, who had investigated this question, found that the sky fog produced in waiting for a spark did not reverse the spark, but that the same amount of sky fog following the spark did reverse it, a curious fact which he had experimentally corroborated, and which he demonstrated by means of slides. This showed that the fog resulting from waiting for a flash might be disregarded, and that, when a flash had been received by the plate, the lens must be at once capped. Knowing that a lightning flash is compound in character, and that it emits Hertz waves, the possibility arose of photographing lightning in daylight by causing the Hertz waves emitted by the first component of the compound flash to go through a coherer, and in that way actuate a photographic shutter. Mr. Glew exhibited and very fully described the manner in which he had adapted a Thornton-Pickard shutter for use with this object, and by means of which he could work the shutter at  $\frac{1}{100}$  of a second, a speed more than sufficient for the purpose. He regarded it as quite possible to arrange a shutter which would capture not only the second, but also the first, component of a flash. The light had to travel through glass before it reached the plate, while the Hertz waves went through the ether. The speed through the ether was the speed of light, whilst the speed through the glass was only two-thirds of that through glass; it might therefore be possible to actuate the shutter before the light had had time to pass through the glass.

Mr. Glew's paper will appear in full in the Society's *Journal*, to which we must refer those of our readers who are interested in the subject, it being impossible here to do more than briefly indicate the lines which he followed.

Mr. J. E. WIMSHURST, in the course of some remarks, said he would be most willing to lend both time and material to the prosecution of further research in this interesting direction.

Mr. SANGER SHEPHERD referred to some experiments which he had made in 1884 and 1887, in which he obtained photographs of dark flashes, and to some theories advanced by Sir George Stokes to account for them. He said he had made many attempts to photograph a flash in daylight, but had not succeeded in doing so.

Mr. W. E. DEBENHAM, referring to the subject of the dark flash, thought it might be regarded as certain that, with the plates in use at the present time, if there were a flash strong enough to cause reversal, there would be on both sides of the reversal line a positive image due to irradiation or reflection from the illuminated path.

Messrs. T. Bolas, A. Haddon, C. F. Townsend, the Chairman, and others also took part in the discussion, and Mr. GLEW having briefly replied, the proceedings closed with a hearty vote of thanks to him for his valuable communication.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 16.—Mr. H. C. Rapson in the chair.

Mr. A. MACKIE showed an artificial negative or sensitometer scale made upon the pattern of Warnerke's sensitometer, and consisting of a series of increasing thicknesses of paper. He called particular attention to a device intended to overcome the reproduction on the test plate of the granularity of the tracing paper employed. For this purpose he had provided upon one side a piece of cardboard, which prevented the test plate from coming into closer relation with the series of densities than the thickness of the cardboard.

allowed. Obviously, if absolute contact between the two were permitted, the grain of the paper would be copied upon the plate, and this would be likely to interfere with the critical nature of the readings. The thickness of the cardboard diaphragm had the effect of forming a cell between the sensitive plate and the graduated standard, resulting at once in a more even deposit and one which could be read with more accuracy than a granular deposit.

Mr. J. S. TRAPE suggested that, if the layers of paper had been enclosed between two sheets of glass, the effect would be the same.

Mr. MACKIN thought that such a course would prevent the formation of a sharp line between the tints, and to facilitate the comparison of tints sharp edges were very necessary.

Mr. TRAPE thought that a sensitometer scale with a double set of graduated densities was preferable to a single one, as by such an instrument two plates of different make could be exposed under identical conditions at one and the same time.

Mr. Tom Bright was kind enough to lend a very fine collection of lantern slides for display. The series embraced specimens of all classes of subject, those of marine and cloud effects calling particularly for favourable mention. The technical quality of the slides, as well as their pictorial merits, was equally deserving of commendation, and the formula adopted in making the slides was considered worthy of trial. It is given below:—

A.	
Pyro .....	20 grains.
Ammonium bromide .....	20 "
Metabisulphite .....	50 "
Water, to .....	10 ounces.
B.	
Ammonia (880) .....	70 minims.
Water, to .....	10 ounces.

Equal parts. Ten drops of a ten per cent. solution of ammonium bromide may be added to each ounce of developer as required, but a proportionately longer exposure must be given. Thomas's plates were used.

Mr. Lewis Medland supplemented the above with a small selection of views in Copenhagen, showing the chief places of interest, statues and monuments, and street life, concluding with some examples of Thorwaldsen's sculpture preserved in the museum of that name, which forms one of the chief attractions of the city of Copenhagen.

**Croydon Camera Club.**—At the entertainment on Saturday, 11th inst., provided by the Croydon Camera Club, the attendance was a record one for the series now being given by the Y.M.C.A. at Horniman Hall. The programme was, moreover, one which seemed to have just hit off the taste of the audience, if a constant accompaniment of laughs and exclamations, varied by applause, are criterions. The President of the Club (Mr. Hector Maclean) had arranged the display, and did the needful as regards explanation. The show opened with a visit to Hatfield, which afforded the lecturer much matter for comment. A peroration, in which the Prime Minister's ancestor, Lord Burleigh, and his Sovereign, Queen Elizabeth, were compared with the present Lord of Hatfield and our illustrious Queen, fairly brought down the house. Many other kinds of notable people and places were touched on. Thus, we had the King of Ratecatchers, with his Royal insignia of silver "Bandicoot" rats; R. B. Lodge ("the Camerist in a Sack"), with some remarkable bird studies; and the Mountaineering Lady, Mrs. Main; some sermons by "Sambourne," of *Punch* fame; the Father o' Pearl; a Man of Many Marvels (Sir David Salomons, Bart.); notable county cricketers, of whom J. T. Brown obtained an ovation; as did Doughty's dogs. Dick Turpin's house, which until lately stood at Thornton Heath, was an interesting scene, contributed by Mr. W. H. Rogers, who also obtained a flattering reception for his sea and cloud effects, as did Mr. A. K. Taylor for his after-dark pictures. A collection of about fifty striking zoological studies by Mr. Henry Sandland brought the slides to a brilliant conclusion; after which Mr. Victor Bender showed, by means of the Velograph, a selection of moving photographs, which the audience were markedly pleased with.

**Hackney Photographic Society.**—February 14, the President (Mr. E. Pattock) in the chair.—A large number of prints were brought up, showing the result of toning with Messrs. Burroughs & Welcome's new sodium-formate tabloids, of which samples had been distributed at a previous meeting. The examples showed that a great variety of pleasing tones were obtainable with the sodium formate, and several members spoke of the economy of the toning bath so made. It had also been observed that the bath would not keep for a second time of using, and that it gave browner tones than sulphocyanide. Mr. J. H. GEAR gave a lecture on

#### HAND CAMERAS.

Dealing, among other things, with the choice of pattern, he said that this would, of course, depend upon the needs of the user, but he personally had a great liking for the twin-lens pattern. The working lens of this should, when possible, be an anastigmat; the finder lens might be a cheaper kind, so long as it was of the same focus. As to shutters, he gave preference to a focal plane working in front of the plate on account of its high efficiency; the next best he considered to be the ordinary roller-blind pattern, working in front of, or behind, the lens. He preferred dark slides to any other form of plate-holder, not excepting a changing box, for the latter sometimes got out of order, and was always more or less liable to cause dust. Concerning the shutter release, the worst possible position for this was at the side of the camera, and the best on the top of the same, for in the latter case the thumb should be used to make the exposure, and the downward pressure should be counterbalanced by a corresponding upward pressure of the fingers below.

**North Middlesex Photographic Society.**—February 20, Mr. Charles Beadle in the chair.—Mr. A. W. W. Bartlett was elected a member of the Society. Mr. H. W. BENNETT, F.R.P.S., gave a lecture, entitled

#### ELEMENTARY NOTES ON LENSES.

The lecturer started by saying that the usual advice to a beginner was, Get a

good lens; but the fact remained that, in the hands of one who thoroughly understood its capabilities, an inferior lens could be made to give better results than a first-class article in the hands of one who understood nothing about it. The lecturer used large diagrams and also the blackboard all through his lecture to make clear his meaning. Rays of light, he said, travelled in straight lines; on passing through a sheet of glass they are bent or refracted to one side, but, on emerging therefrom, go on, if the sides are parallel, in the same direction. If they impinge on a prism, they are bent as before, but on emerging they are bent still more, towards the base of the prism. A lens may be regarded as a series of prisms, with the apex at opposite ends. The rays from a distant object which strike the lens thus meet at a point the other side, which is called the focus. He explained the different forms of single lenses, and that they, in addition to refracting the rays, also dispersed the colours, rendering it impossible to get the visual or yellow rays to coincide on the screen with the actinic or blue rays. This is overcome by combining two different kinds of glasses of different refractive and dispersive powers. The equivalent or solar focus of a lens was the nearest point to it at which objects could be focussed, and is obtained when parallel rays pass through it, as from the sun or any very distant object. He explained the use of stops, and the relation they bear to the focus of the lens; also the method of calculating the focus by getting the image of an object the same size on the screen, measuring the distance between the object and the image, and dividing by four. He explained depth of focus, which did not vary with the quality or kind of lens, but bore a fixed relation to the stop used. The covering power of a lens did not vary with the size of the stop, but the latter affected the defining power. The roundness of the field of most lenses was explained, and the means used to remedy it. The distortion of single lenses was generally much exaggerated, and, provided care was used not to include too wide an angle or get long straight lines near the edge of the plate, they could be used for architectural work quite well. He also touched on astigmatism, and gave instructions how to test a lens at home to find out its capabilities. Several questions were asked by members. One was, How to fix the position of a stop in an unmounted single lens? Mr. BENNETT said it was generally fixed by trial and error, but, as a general rule, it was one-sixth to one-eighth of the focal length, depending on its diameter.

**Richmond Camera Club.**—February 13, Mr. Cambrano in the chair.—Mr. E. MORGAN, of Messrs. Morgan & Kidd, gave an account of

#### MODERN METHODS OF BOOK ILLUSTRATION.

Mr. Morgan first referred to the results obtained by hand work or wood blocks, metal plates or lithographic stones, which, up to the advent of process work, were the usual means of producing illustrations for books. In all these the mode of obtaining the half-tones was by breaking up the white surface of the paper by lines or dots, and Mr. Morgan showed how the same result was obtained in the case of a photographically prepared block by photographing the subject through a glass screen ruled with very fine lines, close together, and crossing each other at right angles. He showed a Levy screen ruled with lines eighty to the inch, and the negative, prepared zinc plate, finished block, and prints obtained by means of it.

**Birmingham Photographic Society.**—February 14 (Beginners' Evening).—Mr. W. T. GREATBATCH gave a paper and demonstration upon

#### PLATINUM PRINTING AND DEVELOPING.

In his opening remarks Mr. Greatbatch said that the process was one of very great simplicity, and the only difficulty to the beginner was judging of the depth of printing, but, after a very little careful work, there should be no difficulty on that score. Sepia platinotypes he considered the finest sepia prints obtainable by any process. It was very necessary with the sepia paper to use a rubber sheet in the printing frame to ensure that the paper be perfectly dry, but this was not so necessary with the cold-bath A A paper. Very pleasing sepia prints could be obtained upon the cold-bath papers by adding a few drachms of a solution of bichloride of mercury to the developer, but he could not say what effect (if any) it would have upon the permanency of the print. For blue-black tones the addition to the developer of a little oxalic acid helped matters considerably. If prints were found to be under-printed, they could be very often saved by raising the temperature of the developer. During the discussion which followed, Mr. C. J. FOWLER advised the use of an actinometer in printing, and it was advisable to write upon the corner of the negative the exposure, according to the actinometer, for future reference.

**Liverpool Amateur Photographic Association.**—February 16.—Mr. F. ANTON gave a demonstration on

#### DEVELOPMENT.

Mr. Paul Lange (President) presided. Mr. ANYON, after dealing with the theory of development, proceeded with a practical demonstration, and developed several negatives, showing under, over, and correct exposures, and how to modify the developer to suit each case. Throughout the lecture frequent discussion arose between the members and the lecturer dealing with the subject. At the conclusion, Mr. JOHN H. WELCH (Vice-President), in proposing a hearty vote of thanks, spoke of Mr. Anyon's merits, and the great benefit afforded the members by the lecturer's knowledge of the art. Mr. Anyon then presented the Society with the three negatives used to demonstrate his lecture. Before the close, Mr. A. C. BALDWIN introduced a new printing paper, Gravura, and, by practical illustration, showed how several different coloured prints might be obtained by its use.

#### FORTHCOMING EXHIBITIONS.

1899.

February 24..... Hastings and St. Leonards. Exhibition Secretary, A. Brooker, 21A, Wellington-place, Hastings.

" 24, 25 ..... Edinburgh Photographic Society. Hon. Secretary, J. S. McCulloch, 2, George-street, Edinburgh.

February 24, 25 ..... Woolwich Photographic Society. Hon. Secretary, F. W. Machen, 161, Griffin-road, Plumstead, S.E.  
 ,, 27-March 4 Birmingham. C. J. Fowler, Court Mount, Erdington, near Birmingham.  
 March 4-11 ..... South London. Hon. Secretary, A. E. Allen, 27, Princes-square, Kennington Cross, S.E.  
 ,, 14, 15 ..... G.E.R. Mechanics' Institution (Photographic Section), Stratford, E. Hon. Secretary, H. W. C. Drury, St. Oswald's, Downs-road, Clapton, N.E.  
 ,, 15, 16 ..... Brentford.  
 ,, 20-May 13 ..... National Trades and Industrial Exhibition, Bingley Hall, Birmingham. Manager, Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### STILL ANOTHER PRINTING PAPER WANTED.

To the EDITORS.

GENTLEMEN,—In view of the issue of new rapid printing development papers, in my opinion the goal is not reached yet or likely to be (for professional use) by this innovation. The difficulty lies in the very rapid development, and consequent difficulty of getting each print of the same colour and depth.

Still it is a step in the right direction, and I should like to suggest that, if makers could issue a paper that, although it could be printed in a reasonable time by gaslight, and then slowly developed, say, half a dozen or a dozen at a time, like toning, so that depth and colour could be deliberately noted, it would be far more acceptable to the professional man, especially if a slightly visible image would give a guide to exposure.

In my opinion, from what I have seen, the old albumen or newer P.O.P. will not be quickly supplanted where time allows for printing out.

OTHELLO.

### APPRENTICES.

To the EDITORS.

GENTLEMEN,—Just a few lines to express my warm appreciation of your leader of last week, "Unanswerable Questions." One cannot but admit that in most cases they could be better solved by the querists themselves with a little observation and theory.

You certainly hit the nail on the head in your remarks as to apprentices and their masters; in such cases the latter are often the first to advertise, "No duffers need apply," and offer sweating wages in the bargain. It is to this class that your article may cause offence, and properly so, for they are degrading photography to the detriment of those firms who work theoretically and believe in fair remuneration both for themselves and their employees.—I am, yours, &c.,  
 AN ADMIRER.

### THE R.P.S. AND PROFESSIONAL PHOTOGRAPHERS.

To the EDITORS.

GENTLEMEN,—As a professional, I trust something practical will yet come out of the letter by Mr. Harris in the JOURNAL of January 6. When I read it, I said Mr. H. at last has "hit the nail on the head."

Of late years there have been many schemes set going to raise the status of the profession. Doubtless, the professionals looked on with mixed feelings on the scheme of the Royal to create or make Fellows. I think whoever started that should be made a knight or K.R.P.S., as it made the guineas to flow on.

But it can easily be seen that one can call themselves members or Fellows of the Royal, and that F.R.P.S. or M.R.P.S. or M.E.P.S. will have the same glitter in the eyes of the public, and won't draw the public if good photographs are not given to customers.

I assert that a man can be an F. or M.R.P.S., and yet not qualified to conduct a business as a photographer. What is wanted now is a scheme or association that can guard the public from any amateur or shamateur who can buy a camera, &c. (perhaps on credit), and start a studio and call themselves photographers or artists.

It is disgraceful and a fraud on the public that any one can be free to rush into business who has no experience or knowledge of the work.

It is this gap which needs to be shut up. One needs only look over your Answers to Correspondents to see the gross ignorance of those who inquire of you about the smallest matters. You would need to do nothing else, but go through these places and instruct these fools who rush in to open studios. I often wonder how long some of them exist.

I could give instances of studios being opened by some ignoramus, and even specimens from others shown as their own work, and, when customers come there not knowing, they only took the photos they had taken for them and put them in the fire.

In justice to the public, I maintain that no one should be allowed to open a photograph business until they have gone through a practical training in a good studio and served a proper time, and then they should have proper credentials to that effect.

No one dare call themselves doctors, or chemists, or even captain of a vessel, who are not qualified, but any sham can open a photographic business and thus deceive the public.

Many professors and even tradesmen protect themselves this way, but photographers have no protection.

This important thing has been lost sight of. Something should be done, but how it should be wrought I leave to others to suggest. Mr. Sutcliffe writes another sensible letter, but no one takes up the subject. I write this to keep the matter from going into oblivion.

Let the Royal and Salon, &c., go on their own course, but that need not hinder the profession from being established on a better foundation than what it is.

I will guarantee that you could find many good practical professionals who have for years kept going a good business, and gathered to themselves a good connexion, and yet that won't qualify them for a F.R.P.S., neither would their work be received at some exhibitions.

It is a pity your criticisms on this last season's Royal Photographic Society Exhibition were not printed in every paper in Britain. *Vide* p. 631 of JOURNAL, September 30, 1898; you there say: "There are some photographs hanging in the Pall Mall just now which we should disdain to criticise in our weekly Answers to Correspondents column." So that is the up-to-date photography! Verily it needs a reformation.

I do not write as a despondent exhibitor, nor yet as one who has not done a good business, but as, yours, &c.,  
 PRO BONO PUBLICO.

[We do not, of course, agree with the writer of the foregoing letter in his criticism of the Royal Photographic Society and its Fellowships; but we refrain from denying it publication, inasmuch as we never refuse a photographer the opportunity of airing his views on a subject of such manifest importance as the advancement of the material interests of his profession.—ED.]

### THE LEEDS CAMERA CLUB AND THE YORKSHIRE PHOTOGRAPHIC UNION.

To the EDITORS.

GENTLEMEN,—Will you kindly allow me to trespass on your valuable space to reply to the mis-statements contained in the speech of the President of the Leeds Camera Club, reported in last week's issue. It is not my intention to dispute the right of this Club to do that which it thinks best for its own interests. The reasons assigned for the action taken were certainly debatable.

Mr. Warren states: first, that other attempts at federation have failed; second, that photographic societies are conflicting atoms, and therefore cannot be federated; third, that the scheme was all Bradford, and that the societies of Yorkshire were to be united to these twelve Bradford gentlemen; fourth, "that the Leeds C. C. was not a charitable institution to give lectures to some societies."

To take the first point. Personally, I am not aware there has ever been any attempt to unite for mutual benefit the photographic societies of Yorkshire, certainly not on the present lines. Presumably, Mr. Warren refers to the Royal Society's Affiliation scheme; but why has this failed in Yorkshire? In my opinion, because of the lack of sympathy displayed towards the movement by the Council of the R.P.S. I could give other reasons: the objections of Yorkshiremen to be tacked on to a London Society; the distance between present organization and subscribing society, making direct representation an impossibility; the advantages offered by the central authorities not being commensurate with the amount paid, and so on.

But a federation of Yorkshire societies, managed by Yorkshire delegates, will suffer from none of these disadvantages.

The second point. I really cannot accept the atomic theory of Mr. Warren as applied to photographic societies. It is not the intention of the Union to destroy the individuality of any society, but to unite societies for specific purposes. Surely friendly rivalry does not of necessity mean absolute antagonism. Why a photographic atom, say, for example, in Leeds, should have no affinity for a similar atom in Bradford, passes my comprehension; and, if one ceased to exist, the one remaining would be not a whit the better, but probably worse. That these so-called conflicting atoms are not conflicting, but have an affinity and a cohesiveness, is proved by the fact that the societies of Yorkshire did unite for the purpose of an Exhibition, which was a pronounced success. The third point is not difficult to deal with. Mr. Warren knows that Bradford is entitled to three delegates, the same as any other society with a similar membership roll. A committee of eight discussed the provisional scheme, and decided to bring it before the Yorkshire societies. The Union being formed, this committee therefore ceased to exist. What

is meant by the twelve conflicting Bradford atoms, I know not; but, as Secretary of that Committee of eight, I can state, positively, they were unanimous that the advantages of a scheme of union were incalculable, and that it was worth a struggle in order to see if the thing was practicable. The last point I prefer not to enlarge upon—no one society is expected to give of its abundance without a *quid pro quo*.

To argue that individuals are conflicting atoms, and that societies are also conflicting atoms, is somewhat puzzling. An individual atom must have some affinity or coherence for other atoms or there could be no aggregated atoms in the shape of societies. To carry the analogy further is useless. Thanking you in anticipation, I am, yours, &c.

113, Chesham-street, Bradford.

EZRA CLOUGH.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

RECEIVED.—T. M. (Newport); A. A. NOAKES; F. S.; H.; and others. In our next.

J. F. BENSON.—No; we do not keep such addresses.

ALFRED UNDERHILL.—The address is Great Windmill-street, W.

E. MOORE.—Yes; you have a legal claim in the circumstances mentioned. You can recover in the County Court.

A. H. (Cardiff).—We are much obliged to you for your letter, the information in which will probably be useful to us on a future occasion.

CROFTHORPE.—At the moment we can offer no suggestion on the lines you indicate, but we will keep your letter before us. By all means call here when you come to town.

PHOTOGRAPHER.—There is no analogous publication issued in France, or anywhere else. Better try the *Moniteur de la Photographie*, published at 51, Quai des Grandes Augustins, Paris.

A. M. Z.—It is recommended by authorities that in cases of over-exposure the bromide should be increased in greater proportion than with other developers. We, however, have had no personal experience on the precise point.

FRANK COGHIAN.—The only way of ascertaining if copyright is in existence is by making a search at Stationers' Hall. In the case you mention copyright has probably run out, but, for the sake of a shilling or two, you had better make sure.

LENS.—R. C. W. The most generally useful lens for an amateur "at a moderate price" is one of the rapid rectilinear type, and not the wide angle. For  $7\frac{1}{2} \times 5$  one of about nine-inch focus will be suitable, and for the quarter-plate size one of about five and a half or six inches focus.

LENS FOR STUDIO EIGHTEEN FEET LONG.—PROVINCE says: "Will you inform me what focus lens I shall require to take a full-length C.D.V. in a studio eighteen feet long?"—A lens of six inches equivalent focus will require from twelve to thirteen feet between camera and sitter, and that is about the longest focus lens that can be employed in so short a studio.

VARNISH.—ILEX says: "Will you inform me what stain or ingredient to add to photo shellac varnish (solvent meth. spirit) to make it a deep yellow, for coating glass, and leaving a yellow film?"—A little aurine, one of the coal-tar colours, added to the varnish will give it a very non-actinic tint. Most of the yellow coal-tar colours are soluble in alcohol and may be used.

COPY OF PORTRAIT.—MIDLAND. We are not surprised that the paper refuses to pay you anything. Why should it? The gentleman paid you for taking the portrait, and he sent it to the paper with permission to use it. You have no copyright in the portrait, therefore it would be no use for you to register it with a view to taking proceedings against the paper. Clearly the proprietors of the paper know the law on the subject better than you do.

OBSCURING GLASS.—P. S. M. says: "The outlook of my studio is very bad—a mews with stables and manure heaps—and I want to obscure the outlook, and do not want to go to the cost of reglazing with ground glass. I have tried coating the glass with Epsom salts, and that is all right when first put on, but in damp weather it is spoilt."—Coat the glass with thin starch or flour paste, to which a little whitening has been added, stippling it on with a brush.

PROTECTING INVENTION.—M. SCOTT. The only way to protect the invention is by a patent. Registration is of no use. A provisional protection for a year is 1*l.*, and a patent for four years 4*l.*—that is, if you take them out yourself. If you get the work done by a patent agent, his fees will be in addition. We should advise you to get provisional protection in the first instance; that will allow you nine months in which to complete the patent or to dispose of the invention if you choose to do so.

MANCHESTER.—1. Collodio-bromide emulsion may be obtained of Messrs. Penrose & Co., Upper Baker-street, Lloyd-square, E.C. Gelatino-bromide emulsion is not now an article of commerce. 2. Roughly from three to six dozen; but, of course, all depends on the thickness of the coating.

BACKING; AND MAGNESIUM FLASHLIGHT FORMULA.—X. Y. Z. says: "1. In your ALMANACK for 1899, the formula for backing (p. 1062), does it prevent halation? 2. Could you please give me a safe formula for magnesium flashlight powder?"—1. Yes. 2. The only really safe magnesium flashlight powder is simply the magnesium by itself, blown through a flame to cause its ignition. All the explosive mixtures containing such things as chlorate of potash, permanganate of potash, &c. are more or less dangerous—more rather than less.

STUDIO BLINDS, &c.—E. P. says: "1. Will you inform me what would be the best colour to have for studio blinds? My studio is 7 feet 9 inches to eaves, and 9 feet to ridge of roof. Two feet from end is board, 8 feet wide glass, which is rough rolled plate, light north. I have light grey linenette blinds now, but do not seem to be able to get much, if any, shadow on the face. 2. Can you also oblige me with the address of a manufacturer of the rackwork for studio stands?"—1. If sufficient shadow is not obtained with the blinds now in use, replace them by dark green window holland. 2. See the advertisements in the ALMANAC for 1899.

PREVENTION OF FRILLING.—P. M. N. says: "Kindly reply how to prevent frilling of films and coming off the glass. I use —. Unfortunately I lost a good order through it, as the gentleman I have taken is gone abroad. The film came off and expanded, and I could not save it."—If the plates be treated with formalin or with alum, it will prevent frilling, but we have never found the brand of plates named to require any such treatment. Had the expanded film been carefully transferred to alcohol, it would have gone back to its original dimensions, and could have been caught upon another plate, and then the negative might have been saved.

OWNERSHIP OF STUDIO.—EDMOND WALLIS writes: "I have put up a small studio in rear of my premises for photographing backgrounds in, and forgot to have anything relating to the ownership of it mentioned in the lease. It is built of matchboards, and stands on bricks. Does it become a removable tenant's fixture if I have it on wood blocks instead, or doesn't that matter if it is not let in the ground?"—We cannot say for certain; but we should say the studio could not be removed as a tenant's fixture, however it is fixed to the ground. The law is a little knotty on the point. For example, in the case of greenhouses, a nurseryman is allowed to remove his, but a private individual is not.

MATERIAL FOR SMALL BACKGROUNDS.—S. BOSEY writes: "I want some material for small backgrounds for sitters, heads and busts, upon which I can rapidly put in some shading or hatching to suit the sitter I am taking. Of course, I want the material to be of a suitable colour, as a light ground upon which I can sketch in with light or dark chalks, and to be inexpensive, as I shall mostly require a fresh background for each sitter."—We can suggest nothing better for the purpose than brown paper; indeed, it is difficult to conceive anything better. It may be had in almost endless length, and nearly five feet wide. It is known as carpet paper, and it may be had at any of the furnishing warehouses.

PHOTOGRAPHING A SILVER CUP.—G. THOMAS says: "I should be extremely obliged if you could give me any information as to photographing a silver cup, which is composed mostly of burnished silver. I enclose you a photo; you will see from that that the burnished parts come out black, and in the stem of the cup there is a great amount of reflection. The cup looks more like ebony than silver!"—Burnished silver is practically black, and should be so shown in the photograph, to distinguish it from the lighter portions. The photograph sent is under-exposed, and the reflections are due to imperfect lighting—all from the direct front. If the lighting had been more from the side and the negative better exposed, the photograph would have been a very good one.

WHITE SPOTS ON PRINTS.—ARGENT says: "Can you tell me what causes the yellow and white marks on the enclosed print? They do not appear till they have been mounted a few days. I use the Crossed Swords brand of paper, and sensitise it in a bath containing 50 grains of silver nitrate, floating it for three and a half minutes. After printing I wash the prints in six or seven changes of water, which take about ten minutes. I then salt them by putting a handful of salt in 2 quarts of water, and leave them in for about half a minute, or till they turn a bright red. I wash them again in about three changes of water, and tone in a bath composed of 2 quarts of water,  $\frac{1}{2}$  ounce of acetate of soda,  $\frac{1}{2}$  ounce of bicarbonate of soda, and enough gold to tone them in twelve to fifteen minutes. After toning, I wash them in two or three changes of water, and fix in a bath containing 3 ounces of hypo to the pint of water for ten or twelve minutes. After fixing, I transfer them to a bath containing a handful of salt to 2 quarts of water, and leave them for a few minutes, gradually letting fresh water in. I give them six or seven changes of water and leave them for the night. In the morning I wash them in running water for two hours, giving them between twelve and fourteen changes. They are then taken out and mounted with ordinary starch, and the marks appear in three or four days. The above refers to twelve or fourteen prints at a time. I have been printing in carbon for the last three or four weeks. Do you think the bicarbonate of potash from the sensitising bath has caused the marks by particles setting on the untuned prints?"—It is impossible to say the precise cause of the spots. They may be caused by particles of pernicious matter, such as bichromate of potash, or many other causes (see article on the subject on page 83 of our issue of the 10th inst.) The prolonged soaking of the prints in water is by no means conducive to their permanency, and may make them more susceptible to disturbing causes.

## EX CATHEDRA.

THE annual ALMANAC of THE BRITISH JOURNAL OF PHOTOGRAPHY is always received in such a kindly spirit by the many thousands of readers, advertisers, and others interested in its publication, that we submit no apology for the insertion of this short reference to the manner in which the thirty-eighth yearly volume, issued last December, "went off," to use the technical phrase. It was not only by far the bulkiest of the series, numbering 1508 pages, but the edition of 20,500 has been practically exhausted in the shortest time on record, namely, in the month of February. Hitherto the process of exhaustion has continued to a much later period of the year. We anticipate that in a very few weeks copies of the 1899 ALMANAC may not be obtainable. One other source of gratification remains to us, namely, the pleasant words of appreciation which the volume provoked in the press. Never before has the ALMANAC met with such a sincerely and cordial reception at the hands of our *confrères*, whom we heartily thank for their help and encouragement.

THE first Traill-Taylor memorial lecture on "The Focometry of Lens Systems"—to give it a shorter title adopted by Mr. Dallmeyer in preference to the one originally selected—has just been issued, revised by the author, in pamphlet form. As an appendix, a description of the Dallmeyer focometer, with illustrative examples of the manner of its use, is also given. Many of our readers will doubtless avail themselves of the opportunity of possessing, in a separate form, this, the first important contribution to the study of optics that has been made by an English author for some years past.

\* \* \*

COPYRIGHT is a subject in which all photographers are vitally interested, and it is to be hoped therefore that not a single person who makes use of the camera will fail to devote some attention to certain efforts which it is proposed to make in the direction of amending or altering the law on the subject. These efforts have their origin amongst a number of artists who propose endeavouring to get a Bill before Parliament, the object of which is to amend the existing law of Copyright in so far as it affects paintings, engravings, sculpture, and allied works of art. Doubtless, very good reasons exist for agitating to secure better protection for the authors' rights and interests in such productions, but we are in no small measure surprised to note what the promoters of the Bill propose to do in regard to photographs. In the first place, the provisions of the Act of 1862 are so far ignored that photographs are separated from works of art (in the Act referred to, no distinction is made), while it is suggested that copyright in photographs, instead of, as at present, existing during life and seven years afterwards, should simply run for a period of thirty years.

\* \* \*

BOTH proposals with regard to photographs strike us as totally uncalled for. The Act of 1862 has, on the whole, worked well in the interests of photographers. On what grounds do the promoters of the new Bill suppose that less protection is needed for photographic copyright now than thirty-seven years ago, when it could not possibly have been foreseen how greatly photography was to grow and become a necessity of modern art and industry? To-day, photographic copyright assumes—nay, possesses—a value to many which can hardly be over-estimated, and yet it is seriously proposed to

reduce that value, to subject to a heavy discount the interest of a photographer in his work, notwithstanding that the introduction of photographic processes has already effected a considerable diminution in the value of that interest. It is to be hoped that, before further progress is made in finally drafting the Bill, representative photographers and photographic institutions will be heard in the matter, so that the rights of photographers will receive the fullest protection. We should have thought that the artists, before having got their Bill into type, would have sought counsel of members of a class who are so vitally interested in that measure. Fortunately, the Royal Photographic Society has appointed a committee to take action in the matter, and no time therefore will be lost in considering how the interests of photographic copyright are affected by the proposed Bill, which certainly should not be allowed to reach Parliament in its present shape.

\* \* \*

THE *West End*, the latest addition to illustrated weekly journalism, previously had a successful career of two years as a monthly. If the quality, get-up, and prosperous appearance of the first number of the paper, in its capacity of a rival to existing publications of the kind, afford grounds for anticipating the career that awaits it, we may confidently predict that the *West End* will secure a position second to none among those beautifully produced weekly illustrated papers which are at once the wonder and the delight of the public. The *West End* very largely relies upon phototypic blocks for its illustrations, and the thirty or more that are given in the first number are of a very high order of merit indeed; truly, nothing finer could be desired. The other artistic contents and the literary contributions are just sufficiently *fin-de-siècle* for readers "outside the movement." Printing and paper are of the best, and altogether the *West End*, which is published at Clun House, Surrey-street, Strand, W.C., makes a bold bid for the success which we have no doubt awaits it.

\* \* \*

OUT of a chatty letter we have received from our *confrère*, Mr. F. Dundas Todd, editor of the *Chicago Photo Beacon*, we take the following extracts, which will, doubtless, be of general interest: "I meant to write you some time ago to let you know that I much enjoyed your notice of your humble servant in a recent issue of THE BRITISH JOURNAL OF PHOTOGRAPHY. I especially wanted to get an erroneous idea out of your head. It was not THE BRITISH JOURNAL OF PHOTOGRAPHY I was aiming at, but — & — The former, or his satellite, writes with an air of patronising superiority that comes from rank ignorance of conditions on this side, and I would simply say this, that if the British photographer does not look out he will be out-distanced by his American cousin just as thoroughly as our mechanical friends have been licked by the American mechanic in the matter of tools. I did not get rid of the big pile of books I figured on last year, but I disposed of 40,000. The war at first knocked things into a cocked hat, and business lay dead for about ten weeks, otherwise I would have done much better; 1899 starts off splendidly, my January business being just double of '98, and Feb. keeps right up. It is probable I may be on your side early in the summer, and, if I do get across you may expect to see me at the Convention, not to teach your folk anything, but just to make notes—possibly to be printed. I send you a sample of my advertising matter, so that you may have some idea of how we push business here, and also learn

that we American publishers are nine-tenths business men and one-tenth editor. My advertising expenses last year exceeded 250%. Are you now catching a glimmering of conditions different from yours? It does amuse me often to read about cold-weather precautions in English publications. We have just finished up a cold spell here, of which I dare say you have heard a little. Look at these figures:—

Sunday morning..... 17° below zero.

Wednesday noon ..... 45° above „

62° difference.

How would your cold-weather precautions work at 17° below, or 26° below, as we had it on Thursday? It has got to be felt to be appreciated. The English people know absolutely nothing about how to decently heat a house, office, or workshop, and I often think how I used to shiver over an open fire, and think that that style of heating was perfection."

\* \* \*

By the courtesy of a friend we have received a batch of free-portrait literature emanating from the Parisian Artistic Photographic Enlargement Company, Limited, of 39, Rue de Constantinople, Paris, of which "R. Leroi" is manager. This Company sends out a coupon entitling the holder to a life-size portrait, value 1*l.*, delivered absolutely free of charge, if the coupon, *plus* a photograph, is sent back within fifteen days. You are very considerably told to "have no fear" that your photograph will be returned to you in good condition. The second document consists of a page and a half of testimonials, all emanating from the North of England. A third is Monsieur R. "Leroi's" letter, in which, after making the offer of a free portrait in the terms in which such philanthropic proposals are usually couched, the writer goes on to say: "In conclusion, we would beg to remind you that you will, no doubt, have already received similar offers from various so-called Artistic Portrait Societies in Paris, who offer you a portrait gratis, but, before you can obtain your portrait, they compel you to either purchase a frame or to remit 8*s.* Please do not confound this offer and our Association with such concerns. We do not only give you the portrait gratis, but we deliver same to your address absolutely free. In other words, our offer is that of a portrait, size 16 by 20 inches, mounted on Bristol, delivered at your own home in about thirty days after we receive your photograph, all without costing you a penny.' If M. "Leroi's" Company has nothing to do with the other Lutetian portrait societies, against which he is so good as to warn people, it is to be regretted that the style, get-up, and phraseology of his circular bear such a close resemblance to that sent out by Messrs. "Tanqueray," Messrs. "Schneider," and the other persevering knights of (photographic) industry at present located in Paris.

\* \* \*

WE are reminded of the imminent approach of spring by the receipt of Messrs. Marion's catalogue of their annual clearance sale, which lasts from March first to the tenth; of the ninety-six pages of that catalogue about half are devoted to photographic goods, amongst which accessories, sundries, shutters, tripods, printing frames, dishes, animatographs, X-ray apparatus, cameras, porcelain ware, lenses, finders, mounts, and many other items are listed in great variety. As in former years, the sale will, doubtless, attract great attention. Catalogues are obtainable free.

## FOCUSSING OCULARLY AND BY SCALE.

THE season for outdoor photography is now fast approaching, and we have already had inquiries from more than one novice, in effect, as to whether they should get hand cameras with fixed-focus lenses or adjustable ones? Of course the majority of our readers do not require to be told that there is no such thing as a fixed-focus lens, or that there ever can be one. There are, however, fixed-focus cameras, but they are hand cameras and mostly of the cheaper forms. Most of the better-class cameras are provided with a focussing arrangement with a scale, graduated, at which objects at different distances will be at their sharpest in the negative. Others, again, of the twin-lens type are usually arranged so that the focussing can be done visually.

Now, the question arises as to which of the two systems is the better in actual practice, i.e., focussing on a ground-glass screen, or relying on the focus as indicated on an accurately adjusted scale. If the latter, why is it not applicable to cameras of larger sizes than the usual hand cameras? It may as well here be mentioned that with very short-focus lenses, such as those used for pocket cameras, an adjustment is scarcely necessary in practice, as the aperture of the lenses rarely exceeds about  $f/10$ , and the focus more than three inches. Consequently all objects with such lenses, beyond about eight or nine feet, will be in good focus or with a lens of four inches focus, fourteen feet, and it is seldom that anything at less than these distances has to be taken with hand cameras. For that reason, with lenses of such short focal, a focussing arrangement is scarcely necessary. But the case is different when we come to deal with lenses of five and a half or six inches, such as are generally used on the better class of quarter-plate hand cameras, and which have the larger angular aperture  $f/5.6$  or  $f/8$ . With a lens of six inches focus and the former aperture there will be a marked difference in the focus of objects situated within, say, a distance of about forty-five feet, though beyond a little more than that all objects will be practically in good focus.

To the users of cameras of the fixed-focus type, even with the shortest-focus lenses, we would say, See for yourselves that the lenses are really fixed at their best foci, for several cases have come under our notice in which they have not been, and considerable improvement might be made in that respect. The same remark also applies to the adjustable cameras with scales; they also have not been correctly adjusted. Hence the best has not been made of the lens when these incorrect scales have been relied upon, indeed excellent lenses have shown only as second or third-rate ones. In many cases, with the cheaper cameras, no more care seems to be taken in the adjustment of the lenses than has been the case with the fixing of the finders. More than once we have called attention to this subject. Rarely do we find, even with costly cameras, that on the finders—vertical and horizontal—the centres of the images coincide with the centre of the ground glass, or the angles included by them correspond with that included by the lens.

The point here, however, is whether focussing by scale is preferable to ocularly focussing for each exposure, and, if so with hand cameras, why not with those of larger size? With small cameras, and a properly adjusted scale—and all depends upon that—it seems that this is the best way in practice, for it is doubtful in many cases, as for example in street scenes or photographing some interesting event, or exciting scene, if so good a focus is secured when it has to be quickly obtained,

visually, as by a rightly adjusted scale. The objection generally urged against focussing by scale is the difficulty of correctly judging the distances applying to the scale. That is, however, more imaginary than real. Most people can judge pretty well if the object be ten, twenty, or thirty feet away, and an error of a foot or two, either way, makes no material difference in the result. When we get beyond, say, twenty feet, with a five-inch focus lens the difference between that and infinity is quite a negligible quantity, particularly if the lens is used with a stop.

As to the convenience of the two systems there can be no question. Seeing that, will it not be, in many instances, equally the case with larger sizes—the whole plate or  $12 \times 10$  for example? In some cases, certainly yes; for example, in photographing dark and badly lighted interiors where the only chance of obtaining a focus is by tapers burnt at different parts of the building. Here an accurately adjusted scale that could be relied upon would not only be a great convenience, but often a better result would be secured. So it often would be in taking instantaneous pictures of moving objects, &c. On this point we have in our minds a series of boating pictures of large size,  $20 \times 16$  or thereabouts, taken with a lens of some thirty inches focus, that were obtained by this method alone. But a considerable time had been expended in carefully adjusting the scale on the camera beforehand, and it is obvious that that need be done when working with a lens of such focus. Also the distance of the different objects from the camera had to be pretty correctly estimated, as in this case they were. Some of these pictures, thus obtained, took a medal at the Royal and other exhibitions some years ago. There is, however, a difficulty in the way of the scale system which must not be overlooked, namely, when the swing back has to be brought into use, but that difficulty is not really an insurmountable one.

**Purification of Acetylene.**—Herr P. Wolff, in *Chemiker Zeitung*, has some very pertinent remarks upon this subject. He alludes to the continual publication of new methods of purification, having for their object the purification of the gas with the purpose of avoiding smoke when the gas is ignited. As a matter of fact, the production of smoke is a function of the burner, and not of gaseous impurities. The only impurity of moment is phosphoretted hydrogen, which Lunge and Cedercreutz have proposed to eliminate by the use of chloride of lime. Herr Wolff had previously noted that this method of purification resulted in the production of a series of small explosions, caused by the nitrogen of the ammonia present forming chloride of nitrogen. To prevent this effect, the ammonia should be got rid of, and this Herr Wolff states can be easily done by simply washing with water. Chloride of lime can safely absorb the phosphoretted hydrogen and the hydrochloric acid at one operation. So pure is the gas so treated that it only possesses a faint ethereal odour, and the warning smell is lost till it is slightly restored by passing the purified gas over a further quantity of carbide, which causes a slight quantity of crude acetylene to pass over and give a sufficient yet not strong odour to the whole. The pure gas is without action upon copper and its alloys, but a trace of impurities will quickly bring about a brown stain on polished bronze ornaments. These stains are said to be not, as is commonly stated, acetylide of copper, but phosphide.

**Low Temperatures and Light Action.**—Professor Dewar's experiments upon dry plates exposed to the low temperatures of liquefied oxygen will be in the memory of our readers; he showed that all chemical action of every sort ceased, and recently MM. A. & L. Lumière have presented a paper to the Paris Academy of Sciences, upon a somewhat similar topic. They state that a gelatino-bromide

plate, when immersed in liquid air, and subsequently exposed to light for a short period, gives, upon development, very little trace of deposit. If plates were dipped into the liquid, and then permitted to resume their normal condition and temperature, they retained all their properties. The experimenters did not find all light action arrested at the low temperature of liquid air; but their sensitiveness, under the conditions, was reduced several hundred times.

**Explosive Actinometers.**—Speaking of explosive nitrogen compounds, it may be noted that, at the last Chemical Society's meeting, a reading of a series of papers of nitrogen iodide, led to the President's remarking that nitrogen iodide had already been proposed for use as an actinometer by means of the results of the decomposition of that substance when light was allowed to fall upon it under suitable conditions.

**New Current Interrupter for Ruhmkorff Coils.**—Mr. A. A. C. Swinton draws attention in *Nature* to a new current interrupter invented by Dr. A. H. Wehnelt, of Charlottenberg, which Mr. Swinton considers to be by far the most important improvement in connexion with these coils that has been for many years introduced. The apparatus is of extreme simplicity, consisting merely of a glass vessel into which dip two electrodes. One of these is a plate of lead of considerable area; the other is a glass tube, through the end of which protrudes a short piece of platinum wire, sealed into the glass. The glass tube is open at the other end, and is filled with mercury, into which is dipped one of the wires from a source of continuous electric current. The glass tube is immersed in the acid, so that the platinum wire is some distance below the surface, and is within half an inch or so of the lead plate. No condenser is employed, the primary terminals of the coil being directly connected with the supply mains (100 volts) through the electrolytic cell, the positive current being arranged to pass through the cell from the platinum wire to the lead. On turning on the current, a rapidly intermittent arc is seen to take place in the vicinity of the platinum wire, apparently between the latter and the dilute acid. Judging from the loud hum, the frequency must be some hundreds per second. At the same time from the terminals of the secondary of the coil, placed some five or six inches apart, a perfect torrent of sparks takes place. The effect is, in fact, very similar to that produced with a Tesla high-frequency coil, but is much more constant and much less diffuse. With regard to the photographic action of such discharges, we should require to have more information before we could form a decision as to whether the innovation is of value or not, for it is well known to experts that for the greatest penetration of the X rays to be obtained it is by no means necessary to have rapid intermittence of current. Indeed, while for diagnosis with the fluorescent screen rapid interruption may be useful, a current of such slow breaks that each one may be counted, and that, in consequence, will not bend the platinum reflector of the Crookes' tube, will give great photographic penetration. These varied effects are well shown in the mercury break sold by Messrs. Isenthal & Potzler, by which the current is under very complete control.

#### ON THINGS IN GENERAL.

WE all respect the utterances of so ardent and experienced a photographic veteran as M. Léon Vidal but whether we are to follow him in his onslaught against the Paris Municipal Council, for voting the immense sum of sixteen hundred pounds for the purpose of having the pictures of Hotel-de-Ville reproduced by engraving, is matter of doubt. "There is nothing like leather," we know of old, still I hope I shall not be considered a traitor to the art if I venture to raise a protest against the indiscriminate reproduction, by photogravure, of all and sundry paintings it is wished to multiply. When one has said that we obtain faithful reproduction by its means, we have said all and more than all. Tone and values are too frequently lost sight of; verisimilitude of outline, it is true, we get; but too frequently that is all, and the more nearly we approach the effect of the original, the

more do we owe to the clever manipulation of the expert handicraftsman, and the less to pure photographic process. We get some good photogravures, but they are the exception; the rule is a something of a nondescript nature, "neither fish, flesh, fowl, nor good red herring." To compare an average engraving with a photogravure is to compare living human flesh with Madame Tussaud's effigies.

That was an excellent discussion at the London and Provincial Photographic Association upon Mr. Welford's paper on "Photographic Society Life." The proper key-note was struck in the references to beginners and their work. Mr. Philip Everitt said, speaking of them, that the old custom of pouncing upon a raw beginner and holding up his work to ridicule was, happily, dying out. Well, this is only half true. Mr. Mackie's remarks were more to the point when he said that the treatment accorded to beginners was to a large extent dependent upon the attitude they assumed. To show a bad result for admiration was a sure means to invite ridicule; but he thought a beginner who brought forward his work with a view to acquiring better knowledge stood in no fear of such treatment. Quite true, Mr. Mackie; but does such a *rara avis* exist as the modest beginner? My experience of the race is that, when they have had a camera for, say, a week's time, they know absolutely everything it is possible to know. Time was when, in conversation with such a one, I would spend a good amount of time in explaining things, perhaps putting him in possession of some little tip, of which, or its use, he had previously been absolutely ignorant. And how would he take my aid? Not like Mr. Mackie's modest learner, anxious for information; no, he would merely reply, "Oh, yes, that is a capital plan," with an air as though he absorbed the knowledge with his mother's milk. He is ten times worse than an amateur painter, and we all know him. I was once shown a portrait painted (life size) in water colours by one of the latter. "What do you think of that?" he said. "I've just been to the Royal Academy, and I didn't see a single portrait on the walls that I liked so well." I assure my readers I am not jesting. My only resource was to fall back upon technique, and suggest that I thought he might get even still better results if he did not use Prussian blue (!) in his flesh shadows. A week after, he came to me again and said how much improved his work was for my tip. Now, no photographic amateur that I ever came across would have admitted that; he would have assumed that he threw all his Prussian blue in the fire such time as he used to place his sister's wax doll there. I don't really think, after all, there is such a thing as a photographic beginner in the sense implied in the discussion, unless it is a man who has just looked in on his return from his first photographic purchase.

I was much interested in Dr. Steinheil's paper upon the use of the tele-photo objective for astronomical purposes, wherein he shows the uselessness of the instrument for all except solar work. This will, perhaps, be a disappointment to many, but it is well to place on record all such limitations, so as to give a practical turn to the work of the many enthusiastic photographic workers with some photographic knowledge, and prevent their wasting time merely on the impracticable. I know a very clever photographer, equally skilful with his equatorial, who was on the point of buying a large single achromatic photographic lens to work at *f*-8 for fine stellar photography. He could not at once understand that a lens made to embrace an angle of at least twenty or thirty degrees could not be expected to give definition equal to that from a telescope objective corrected only to a tenth part or so of such aperture. I often wonder, seeing the *modus operandi* has been so often and well described in this JOURNAL, some one possessed of a good rapid rectilinear or anastigmatic lens of a couple of feet focus does not show what can be done by taking a snap-shot of the moon, and enlarging the small negative so taken. A very fair picture indeed could be so obtainable, and, indeed, a stereoscopic view of the luminary, an inch or inch and a half in diameter, might be produced by taking two views—one an hour after the other. Parallax equal to that from the two eyes directed upon an object ten or twenty feet distant would be given. The word parallax calls to mind the well-known lecturer who some years ago used to lecture in all the large towns on the subject of the rotundity of the earth. He was a clever man, and defended his position, that the earth was flat, with wonderful skill

and subtlety and plausible casuistry. One of his arguments in favour of his explanation of the whole solar system was that the moon gave off no heat, but, indeed, its rays were the reverse of hot. His arguments would have had an unfortunate termination if Lord Rosse's recent lecture at the Camera Club, showing how he had measured the heat of the moon's radiation had been delivered at the time. But the greatest of men are caught tripping sometimes. For example, I read the other day that "Mr. Dallmeyer, in a recent letter, pointed out to us that when a lens is focussed for infinity the focus of a negative lens required to bring any object into sharp focus without moving the plate is simply the distance of the object itself. This is a convenient little rule to bear in mind in such cases." I don't believe Mr. Dallmeyer ever wrote such a thing. To use a negative lens to cause the focus set for parallel rays to be correct for near objects is obviously absurd, and, further, to believe that he ever suggested that one and the same correcting lens was, under such circumstance, equally applicable whatever the focus of the original lens, is simply incredible.

Mr. Burrill's paper, read at the Leeds Camera Club the other day, was an interesting contribution to the knowledge of materials, but he went rather too far in his recommendations. Who, for instance, uses distilled water for making up his developing solutions? Yet Mr. Burrill laid stress upon the necessity of using pure water. Possibly, however, the abstract of his paper may not quite give the true sense of his words, and that pure, i.e., such as one could only in practice get in distilled water, was not intended. In any case, it may be safely asserted that distilled water is not necessary for compounding a developer with.

I noted at the Photographic Club the other day some one asked how to remove the yellow stain sometimes got with the ferricyanide reducer, the general opinion being that they could not be removed. In a sense that is so; but a five per cent. solution of citric acid will take them out, only, however, to return again if sufficient washing to remove the acid be given. One word more about the various toning methods of old. I find "A. W." writing that the phosphate of soda in toning was only introduced after the alkaline system was adopted—the carbonate, acetate, citrate, borax, *et hoc genus omne*. Now, it is not generally known that one of the later editions of Hardwich gave a method of compounding a citrate of soda toning bath of most excellent quality. This attracted virtually no attention, and, when the "alkaline gold toning"—carbonate of soda—was introduced, it was never heard of. I believe I am correct in saying that the next variation was the phosphate by Mr. Maxwell Lyte, and later came the acetate fathered by PAbbe Laborde. I am writing from memory, but I think correctly.

FREE LANCE.

#### FERRO-GALLIC COPYING PAPER.

THIS method of printing is due to Messrs. Schering, of Berlin. From a drawing in black lines upon a white ground, it gives, after exposure to light and development in water, a copy also having black lines upon a white ground.

Such positive copying paper, say Messrs. Schering, is produced by coating in the dark, by means of a rotating roller or other suitable apparatus, the ordinary so-called ferro-gallic paper (which is a paper containing ferric chloride and tartaric acid, and is usually developed by gallic acid) produced according to any of the known methods, either upon the side sensitive to light, or upon the reverse side, with the solution of a mixture of a body colouring iron oxide salts, for example, gallic acid, tannin, pyrogallol, and the like, and of an acid which prevents the premature formation of a dyestuff between the developer (gallic acid) and the light-sensitive salt (ferric salt), and does not itself darken the ferric salt in a suitable solvent, which does not dissolve gelatine and rubber, for example, alcohol or ether, and thereupon quickly drying.

The paper so produced is, in the usual manner, placed in the light under a drawing in a copying frame. After exposure, the paper is washed with a jet of pure water or placed in a vessel with a quantity of pure water, whereupon the drawing at once comes out black upon a white ground.

The preparation of the ferro-gallic paper with the solution of a mixture of gallic acid and the like, and of an acid which prevents the premature formation of a dyestuff between the developer (gallic acid) and the light-sensitive salt (ferric salt) and does not itself darken the ferric salt, which does not darken iron oxide salts, has many advantages. For instance, gallic acid alone in alcoholic solution gives to the ferro-gallic

paper treated therewith a black violet discolouration, which renders the paper unusable, this is absolutely prevented by the presence of the acid; the iron salt contained in the ferro-gallic paper remains, on the contrary, unaltered. Gallic acid alone, which, up to the present, has been rubbed upon the paper in a pulverised form, diminishes its sensitiveness to a considerable extent, by the use of a mixture of bodies darkening iron oxide salts and suitable acids; on the contrary, the sensitiveness of the paper is not only not prejudicially influenced but rather increased. Further, the development of the copies in water by the use of powdered gallic acid takes a long time, for the gallic acid is difficultly soluble in water, and the blackening of the iron salt is thereby retarded.

Dissolved gallic acid, on the contrary, operates, on account of its fine division, almost immediately, so that the development of a photogenic copy only takes a short time.

The presence of such an acid has also a purifying action upon the white ground of the paper, so that photogenic copies are obtained of much purer white.

To make positive photogenic copying paper producing violet lines upon a white ground, the following may be used.

Ordinary positive copying paper, the so-called ferro-gallic paper, is coated with a solution of—

Gallic acid .....	150 to 200 grammes.
Tartaric acid .....	50 „ 80 „
In alcohol .....	1000 c. c.

Instead of gallic acid any other salt, in suitable quantities, rendering iron oxide salt dark—for example, pyrogallol, tannin, and the like—may be used; instead of tartaric acid, citric acid, oxalic acid, anhydrous acetic acid, alcoholic, hydrochloric acid, or other acid not darkening iron oxide salts may be used; instead of alcohol, any other solvent capable of dissolving the before-mentioned substances and acids in sufficient quantities, which, however, leave the substances contained in the ferro-gallic paper unaltered, as, for example, ether, amyl-alcohol, acetone, methyl-alcohol, and the like may be used.

By a suitable choice of the bodies which colour iron oxide salts different shades of black, as also other colours, may be obtained.

#### ALBUMEN AND GELATINE PAPERS.

IT is now some time since albumen was superseded by gelatine in the preparation of photographic printing papers. Its rapid adoption and almost universal use in place of albumen, that for so many years had held its own without a rival, indicated that there was some deficiency in the albumen surface that workers were anxious to remedy. Gelatine, offering the desired immunity, was received, so to say, with open arms. It may be pertinent to ask if the gelatine has been found all that was hoped for, and so superior to the albumen it has, in a measure, supplanted, that the older process may be considered nearly obsolete, or in a fair way to becoming so.

Two serious charges were made against albumen: one that the prints so soon faded, and that the surface was not so perfect as could be desired. I fancy the beautifully even and grainless surface of the gelatine paper was the chief factor for its undoubted popularity; as to its superior permanence, it is a matter of considerable doubt if it is in any way superior, or even as good, as albumen. I think we may safely say a carelessly prepared gelatine print is very much more fugitive than one badly prepared on albumen; but perhaps fugitiveness, in many instances, is a blessing in disguise. It is not, however, fading that is the worst quality, but rather the dirty, sickly appearance, a yellowing of the whites of the print, that imperfect preparation generally induces, and that at an early date, in many instances even before they are washed and dried. The familiar P.O.P., which has in so many instances taken the place of albumen, and is the only kind of printing-out process known to a great proportion of amateurs, possesses qualities both superior and inferior to albumen. If extreme glossiness and the possibility of making fair or passable prints from poor, thin, over-exposed negatives were the principal objects, P.O.P. would undoubtedly be a long way ahead; but, given a negative of good quality, the results on an albumen surface would be more pleasant to look at, and more than equal its rival in artistic effect.

Unfortunately, owing to careless preparation in one or other parts of the process, many albumen prints look crude and deficient in delicate nuances of tone, that are beautifully apparent on the negative; but this is not the fault of the process, but of carrying it out, and depends not on any single, but on every, part of its preparation—printing, toning, fixing, and washing, any one of which badly or injudiciously done will put its mark on the finished picture; whereas with gelatine the print may be bad, but the half or more delicate tones will not suffer in anything like the same proportion; there is, in fact, an amount of half-tone, some of which might be well spared. The amateur, as a rule, looks for a method of working by which all trouble is minimised, even to adopting that abomination, the toning and fixing bath in one solution, that will, unfortunately, produce a print pretty enough in the first instance, but many times more fugitive than the worst albumen print that ever was made, and one that in a very short time becomes yellow and patchy. In looking over a large number of mixed prints on albumen and gelatine respec-

tively, I was struck with the deterioration that had taken place both in brilliancy and colour in the gelatine prints in the course of four or five years, in the colour especially.

Albumen prints ten or fifteen years old were brilliant in comparison, and in every case superior to the gelatine ones—in fact, many showed no signs of any alteration, and were as good as when first printed. That could not be said of any one of the gelatine when only a couple of years had passed over them and they had been closed in a folio nearly all the time. It may be said care was taken in preparing all these prints, so it was not from careless preparation, but evidently from faults inherent to the process. The usual sulphocyanide toning bath was used in all cases, and fresh hyposulphite fixing solution more than sufficient for the number of prints prepared at a time, with a thorough and careful washing afterwards; and yet the prints had become wofully shabby, which term expresses just what they were. When these are the results with careful preparation, what is more than probable will take place with carelessly prepared ones in a few months is easy to imagine. When we contrast the rough, slap-dash way in which thousands of albumen prints were made—fixing bath black with constant use, toning that scientific opinion would attribute to sulphur not to gold, and washing, well, a dip and a swill and little else—and yet they have lasted, probably rather yellow in the lights, but many of them fairly strong images after dozens of years, and quite copyable, if there was any necessity of perpetuating the image, gelatine prints, it is safe to say, would have had the decency to pass out of existence altogether in a fraction of the time.

But it is not the permanency of prints, but rather the appearance of them, to which I desire to draw attention. The charge has been frequently brought against albumen paper that it fails to produce the delicate detail there is on the negative, which charge is frequently correct, but not so when the process is blamed; it is the carrying out of the process that should be found fault with. Provided the paper is good as a foundation, over the preparation of which, in a general way, the photographer has no control; but, given a well albumenised paper and proper attention paid to the different processes it has to undergo, no other paper will give more satisfactory results in this respect, combined with brilliance and delicacy. Care should be specially given to depth of printing, condition of toning bath, and freshness and strength of the fixing solution, and, finally, to the length of time in the washing water. This latter condition is most important as affecting the *brilliance* of the print. All large producers must have noticed it. In course of business, prints are frequently left washing from Saturday night to Monday morning, with the result that Monday's prints are always duller than those prepared in the rest of the week that have only had one night's washing; but, if the one night in the water was curtailed to one hour, there would be a wonderful gain in brightness; energetic washing for a short time, if properly done, even for half an hour, not only leaves a more brilliant but more permanent result. The long-continued action of water sets up incipient decomposition with all its induced faults, yellowing, fading, *et id genus omne*. In the first place, let the printing be done in good diffused light to a proper depth; here, at any rate, we have all the detail there is in the negative. Afterwards come those processes that, improperly performed, destroy it. The toning bath being a little out of condition may dissolve the more delicate tints, and the fixing bath may be of the wrong strength or temperature, and do the same. Between them, the print, although brilliant, is deficient in delicate detail, and the process is blamed for injudicious manipulation on part of the worker. I cannot help but think that, after a time, albumen will once more be taken into favour, unless some other process is introduced that may be at present in the womb of futurity.

In this article I am merely comparing the ordinary glossy P.O.P. with albumen paper as used for the bulk of general work. Of course, with platinotypes and other matt-surface papers, for artistic effect albumen is not in it. Some of the modern papers and a good negative leave nothing to be desired for artistic effect judged by the highest standards. From very early days there has been a desire to have such prints, prints that would be brilliant and delicate without gloss, but it is only of late years that we have been able to do so. Many attempts were made at matt-surface prints, but they never seemed to be appreciated; possibly they were not sufficiently good. The majority of them were produced by floating ordinary albumen paper on the back and printing on the back, or by the use of plain salted paper. Providing a pleasant colour could be had—and that was not easy—when finished they had a wretched sunk-in appearance, although in the washing water they looked exceedingly nice. The effect of a large print on Whatman's drawing paper salted was particularly good when wet, but, like the rest, on drying, detail went out of the shadows, and a more or less sunk-in appearance supervened. With all such surfaces it was necessary to use a very strong negative; a soft, delicate one was useless. So, to begin with, getting detail in the shadows was severely handicapped. The crowd would, however, have none of it, so the photographer, who had to consider his profits, stuck to shine and vulgarity. How our leading portraitists of those days—William, for instance—would have appreciated our modern matt surfaces one can well imagine. His well-managed vignette heads would have further added to the estimation in which he was held for this particular class of work, and the charming productions of the leading men in Paris, Vienna, and Berlin would have been more charming. I

am, however, afraid it will be a long time before the public is drilled into a frame of mind to like matt rather than glossy prints, although the most appreciated pictures at our exhibitions are made on it.

What fascination a print of moderate size, say, whole-plate, with a surface like looking glass, can have, I am at a loss to divine; but, at the same time, I must confess to a liking for very small prints on a bright surface, where it is important to show the smallest detail clear and distinctly, but beyond this their very shiny surfaces have a commonplace vulgar effect. A smooth surface is unobjectionable, and must not be confounded with a shining one, which is a different thing altogether. Complaints were made of the detail in the shadows not showing sufficiently on albumenised paper, and the manufacturers have gradually contrived to so prepare it that the image remains mostly on the surface, and the gloss is better than formerly, and certainly shadow detail is improved. It has also had the effect of preventing its being used as formerly by floating and printing on the back when a matt surface was required, the salting not penetrating into the body of the paper. This is, however, now a matter of little importance, other matt-surface papers being readily available, and much more suitable than the makeshift plan we had formerly to adopt. When detail in the shadows requires accentuating on albumen paper, waxing the print will improve them without adding much gloss, and incidentally will have the effect of protecting them against atmospheric action to a considerable degree.

One great advantage P.O.P. has over albumen, in the eyes of the small consumers, is its keeping qualities, which are superior to albumen papers even when purchased ready-sensitised. Albumen paper will, in a time insufficient to cause discolouration, tone badly, whereas the P.O.P. does not alter in this particular whilst it remains white; either, however, keep very well with proper storage. Home-sensitised albumen paper much more readily deteriorates, especially in hot weather, unless special precautions are used to preserve it, than which nothing is more effective than superposing a sheet of carbonated paper upon the face of each sheet of sensitised paper, and keeping under pressure until required for use, and then backing it up in the printing frame also with the carbonated paper, in fact keeping it in contact with it until ready for washing. Albumen paper is also more pleasant to handle throughout the different processes, and very much less liable to get damaged, which should be considered in its favour. Most ready-sensitised albumen papers are preserved with acid, and acid in the toning bath invariably upsets it; the precaution of passing the prints through a weak solution of carbonate of soda before toning should be invariably practised, of course washing off the soda before toning, then much of the difficulty of getting good coloured prints would vanish. Again, the adaptability of albumen paper to all qualities of negatives is distinctly in its favour, except, as I have remarked, from thin, weak, or foggy negatives; but, whatever process is adopted, a good negative is the foundation of good prints. EDWARD DUNMORE.

#### A NEW SYSTEM OF FILM PHOTOGRAPHY.

MESSRS. MOH, HESERIEL, AND GRÜNEWALD, of Berlin, the authors of this invention, point out that a sensitised film may be exposed in the known manner, developed, fixed, and washed as usual, and then strengthened, that is to say, rendered thicker, with a gelatine film by pressing the two films together in a moist condition. There is thus obtained a strengthened negative sheet or film which may be treated like any other negative sheet, but can be copied from both sides with the same sharpness. The photographic image is produced in the camera upon an improved negative paper, which we will now describe. This negative paper comprises a suitable sheet of paper as a carrier for the sensitised film, which film consists in turn of three different films, viz.:

- (1.) A rubber film, which rests directly on the paper to which it adheres.
- (2.) A collodion film intimately united to the rubber film.
- (3.) An upper gelatine film as a carrier for the sensitising material.

These three films together constitute the negative sheet or film, of which the paper serves as the carrier. The negative paper thus constituted is exposed to light in the camera.

In the following description the combination of the negative sheet or film with the paper will always be referred to as "the negative paper."

After the negative paper has been exposed in the camera, developed, fixed, and washed, it is dried, and it then possesses the property of allowing the negative film to be stripped from the paper backing. The rubber film adheres sufficiently firmly to the paper to permit the various operations of developing, washing, and so on, yet not so firmly as to prevent the stripping off of the sheet; a smooth and easy removal of the negative film from the paper is thus possible. The negative sheet thus obtained is rather thin and liable to pucker or form wrinkles, which is a hindrance in copying. In order to remedy this drawback, the negative sheet is preferably strengthened, *i.e.*, rendered thicker. For this purpose a gelatine paper of similar constitution to the negative paper above described, but with this difference, that its gelatine layer contains no sensitising material, is immersed in water and united to the original negative while this is still upon its paper backing, so that both gelatine films adhere to each other. The two negative papers are then pressed into intimate contact by rolling or other suitable operation, and the resulting

sheet is hung up to dry. After drying, the two paper-backing sheets between which the strengthened negative film is contained may be stripped off, and a stronger, thicker, and smooth negative film is thus obtained which does not roll up and can be copied from both sides.

Besides the strengthening effect referred to, a further useful effect is produced by the employment of an adherent sheet as just described. The rubber film of the second or strengthening negative paper, which rubber film is in direct contact with the paper, receives an impression of the grain of the paper. It is thus possible by choosing a suitable paper to impart any desired grain to this rubber film. The grain thus imparted to the rubber film may thus serve as a substitute, either wholly or partially, for retouching, since the rays of light are dispersed and distributed in copying by the grain. Inequalities or ruggedness of the image or picture are thus suppressed by means of the dispersion of the rays of light by the grain without loss of any of the characteristics of the picture. The sheet of different grain secured upon the original or sensitised sheet thus acts as a substitute for the slow and tedious operation of retouching the negative. With a little easy touching up, results may be obtained equal to those of artistic photography and such as have hitherto only been obtained by tiresome and tedious labour. It is evident that the strengthening film must be selected in varying thickness according to the size of work. It is further obvious that for a landscape a strengthening film with little or no grain should be employed. In the case of portraits the coarseness of the grain would increase with the size of the head in order to obtain the right effect.

The employment of the negative paper herein described for the production of negatives obviates the drawback occasioned by the necessity of rendering the negative to be copied transparent with oil which has hitherto existed because, according to the present invention, the paper backing is stripped from the negative sheet and is no longer present when the copying is effected. A great improvement as regards the strengthening, i.e., the thickening of the negative sheet, is that the two moist gelatine films, which have been smoothly and completely united to their backing sheets prior to pressing them together, return to their original size after pressing, regularly and without forming blisters or turning or curling over; a completely flat sheet is the result. A further advantage is that the negative sheet is completely protected during drying from dust and dirt by means of the superposed paper.

#### THE LIPPMANN PROCESS.

By the courtesy of Messrs. Fuerst Brothers we have been favoured with the following directions for taking photographs in colours, communicated by Professor Lippmann, the author of the process, to the Société Française de Photographie:

Dissolve 4 grammes of gelatine in 100 grammes of water; add 0.53 gramme bromide of potassium. For orthochromatising, add about 6 c.c. of alcoholic cyanine solution (1:500), and 3 c.c. of alcoholic solution quinal-in-red (1:500).

After having mixed the above ingredients and reduced the compound to a temperature below 40° C., add, in a dark room, 0.75 grain dry-powdered nitrate of silver, and stir for a minute or two until dissolved. Filter through glass wool; pour it over the glass plates, which have been warmed, in the same way as collodion.

Let the plates cool on a flat slab of very cold marble, wet each plate with alcohol before washing, then wash for half an hour, drain and dry it. The plates are then ready, and can be kept for a long time.

Before use, moisten the sensitive emulsion with the following solution:—

Alcohol, absolute .....	100 grammes.
Nitrate of silver .....	0.5 gramme.
Acetic acid, glacial .....	0.5 "

Shake and dry. The plate thus manipulated increases its sensitiveness, but must be used the same day.

Expose for about two minutes in sunlight before a Zeiss 6.5 lens.

#### DEVELOPMENT.

Any developer may be used—amido, eikonogen, &c. Perhaps the best effect is obtained by MM. Lumière's developer:—

I.	
Water .....	100 grammes.
Pyrogallie acid .....	1 gramme.

II.	
Water .....	100 "
Bromide of potassium .....	10 "

III.	
Caustic ammonia .....	
Density 0.960 .....	

For developing take—

Solution I. ....	10 grammes.
Solution II. ....	15 "
Solution III. ....	5 "
Water .....	70 "

It seems to be more advantageous to develop little and to intensify with bichloride of mercury and with amidol.

One can also develop very well with a dilute solution of ammoniacal protoclauride of copper.

For fixing after intensification use cyanide of potassium.

#### THE JOYS AND SORROWS OF PHOTOGRAPHY.

BEFORE the Leeds Camera Club, on Wednesday, February 22, "The Joys and Sorrows of Photography" was the subject of a most humorous and instructive lecture by Mr. E. P. Newstead ("Peter Elland," of the *Junior Photographer*), who in the course of his remarks said variety was the spice of life, and the photographer got it, for, whether in cycling, footballing, fishing, or any other pastime, the gentle art of photography exceeded all. It was a great joy to go abroad in bright weather, and find plenty of good subjects; the sorrow came in when all your pet subjects were found spoiled, either with being wrapped in newspapers, or perchance from broken negatives. To go to the seaside and bring back mementoes of your holidays, with brilliant light, what a number of exposures you can get! But, if it rains all the time, then the sorrows come in. The fairest craft may be photographed with the sea in its calm mood, and further inland the sheep grazing quietly amidst the graves in some old village churchyard, and their reproductions would be things of beauty and joys for ever; but on developing, if you found (as often photographers do) the little ships and the little sheep on the same plate—well, words could not express it; the sorrows again came in. The hand camera secured you many interesting records of Jubilee processions, &c., and it was very disappointing to find at the critical moment a man had passed to catch his train, or something else had completely covered all your view. Again, in portraiture, how often it occurs that your sitters will be frivolous; you want expression, and you talk to them seriously. The result is another of your sorrows; you get an expression of a different kind. Children make capital subjects; they compose so easily, and with care you can get a pretty joy, which you can call "Watching for Father," &c.; but, when the child's white blouse is so mixed up with the white wall at the back that you cannot tell a nice little boy from the wall, then the subject is a sorrow which would form a good *Tit Bits* puzzle. One of the joys is the fact of your being able to visit foreign places, and on your return lecture upon them; and you bring back many slides, with a map and a stick, you rattle off a lot of outlandish names, and you are considered a great traveller; sorrows, however, are apt to crop up when some one of your audience, who may have lived there is inclined to ask you awkward questions; and your slide of *Omar's Tomb* (which has got in some way by accident) is pointed out as being really some old mosque or other, a few thousand miles farther away. There are many things to do, and there are many more to avoid doing, and the photographer, to succeed, must go through great tribulation; but the art is free from sameness, and the lecturer did not think anybody would be deterred, for, on the whole, the joys outweigh the sorrows, though it may be beyond the power of man to ever say with certainty whether his negatives will produce fine results or exactly the reverse.

#### PERSISTENCE OF VISION AND RAPID VISUAL SIGNALLING.

At the United Service Institute last month, Mr. E. S. Bruce, M.A., delivered a lecture on "The Relation of Persistence of Vision to Modern Rapid Visual Signalling." Lieut.-General Sir Andrew Clarke, G.C.M.G., presided. Mr. Bruce said it had been his privilege to add another instrument to the list of those devised for illustrating persistence of vision. The instrument, which he called the aerial graphoscope, while it showed the general effects of persistence of vision in a striking manner, so that a whole audience could see them, carried its penetrative qualities of instruction further than the old instruments designed to illustrate the phenomenon; for instance, it appeared to be the only instrument which showed the difference in intensity between the real image and the incidental image, and the gradual fading from the retina of incidental images. It also formed a most delicate test of the exact duration of persistence of vision on the individual retina, and it was in this second capacity that it applied to the relation of persistence of vision to modern rapid visual signalling. The vital principle of the instrument was a narrow lath of wood painted white in front, with a grey centre gradually diminishing in shade to white. This lath could be rapidly revolved at its centre by means of a multiplying wheel, or, if preferred, by an electric motor. On the lath he threw a small portion of a magic-lantern picture. When the lath was revolved rapidly, they saw the whole picture before them apparently in space, the explanation being, that as the lath revolved it received the different parts of the picture in turn. Owing to the fact that the retina of the eye retained for a short time any impression presented to it, the various portions had not time to fade before the whole picture had been successively projected on to the lath. The exact time that the persistent image remained on the retina varied with the intensity of the illumination with which objects were perceived, and with the sensitiveness of the individual retina. Probably also the perception of persistence varied with the sensitiveness of that complex mechanism which connected the rods

and cones of the retina with the grey matter of the brain. It is conceivable, too, that the brain itself had a part in determining the time of persistence. By means of actual tests with the aerial graphoscope, he had found that the same person could have a very different capacity of persistence of vision at different times of the day, according to the circumstances under which he was placed; for instance, within a few minutes his capacity of persistence of vision showed different durations for objects viewed under the light of different colours, or varied after a few minutes' violent physical exercise. The apparatus promised to be useful, not only in physiological laboratories, but in schools of army and navy signalling, as a means of testing the retinas of would-be signallers as to their capacity of persistence of vision. It would seem that bodily fatigue tended to prolong persistence of vision, which, he believed, was the tendency of illness. A light inside a signaller's lantern was visible, through persistence of vision, when the shutter obscured the actual light from reaching the eye. In reading the signals the signaller was discriminating between real and incidental images, a rather delicate operation, for the difference between real and incidental images was one of degree of illumination. It seemed evident that the signaller's sharp reading of dot and dash would depend upon the persisting capacity of his retina, and that a good signaller was likely to be one whose persistence of vision was abnormally low. The possible modification of a signaller's capacity for persistence of vision after fatigue might explain unexpected deficiencies in signalling which may have been in the past ascribed to indolence or carelessness on the part of an individual. Since signalling with flags was more fatiguing than signalling with lantern or heliograph, the former method of signalling would seem to tend to diminish the competency of the retina sooner than the latter. He hoped that those in authority would think the method of testing for persistence of vision worth a trial. Colonel Keyser said there was a great deal in Mr. Bruce's system. It was heart-breaking work for an instructor in signalling to find that in some cases all his labours had been thrown away. The men might have worked hard and done their best, but some of them had not got the quality of sight for the work, and therefore failed. Perhaps it would be useful to send men to the hospital to have their sight tested before they were allowed to join a class for signalling.

#### AT THE CAMERA CLUB.

THE lecture given on Monday, last week, by Mr. Horace W. Monckton, on "Glaciers and Flords in the Bergen District of Norway," stands out from the usual run of tourist lectures, in that it dealt with the Norwegian scenery from a distinctly geological point of view. Many persons have pointed out how valuable are photographic records of geological action, but the labourers in that particular field are few, and it is seldom, consequently, that we see a good photographic illustration of the earth's movements in past times. That this is the case will be at once conceded if we glance at any modern text-book of geology, when we shall find that sectional views of the earth's crust are invariably presented, not by photographs, but by outline drawings. All this will, of course, be altered in the future, but Mr. Monckton's pictures show us that it could be done now.

Although it was not pretended that the pictures had a higher aim than scientific illustrations, some of them had high artistic value as well, and elicited much applause from a rather critical audience; but, they gave the idea that the original negatives would have afforded better transparencies in more experienced hands, a not uncommon thing with amateur lecturers who prepare their own slides.

Nature's operations have been upon so grand a scale in Norway that mountains and valleys, streams and waterfalls, generally looked dwarfed in a photograph, but Mr. Monckton has successfully endeavoured to avoid this by a happy choice in the point of view, and by managing to get foreground contrast. He was able, by his pictures, to trace the formation of a valley, and to illustrate how, in ancient times, that valley was filled up by ice, and how, by glacier action, rocks, stones, and *débris* generally, were carried from afar to form a dam to the land-locked water in after-years.

We were also enabled to watch the progress of a modern glacier, fed by mountain snow, and terminating in vertical cliffs of ice, pierced in one case by a magnificent cave. Such an ice cave is not, however, of annual occurrence in the same situation, but is a freak of nature which may appear one year and be absent the next.

Other photographs showed how a lake might be gradually filled up by the *détritus* from decomposed rocks around, and how below the steep sides of a perpendicular cliff by such degradation would form a huge talus, or mound of earth. In other cases we saw long trails or *scree*s of loose blocks which have been split off by the action of frost and heat from the rocky heights above.

There was one very interesting picture illustrative of volcanic action, perhaps the best of this particular kind that we have met with, showing the intrusion of a basalt dyke into a mass of rock of quite another kind, this black wall of eruptive material having a very curious effect. On the whole, Mr. Monckton may well be congratulated upon his pictures, and

upon the interesting remarks which, wholly without notes, he made upon them.

Dr. Armstrong occupied the chair, and echoed the feelings of the members when he said that the lecturer had afforded them a very enjoyable evening.

#### THE WOOLWICH PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THE Fifth Annual Exhibition of the Woolwich Photographic Society was held at the St. John's Schoolroom, Wellington-street, Woolwich, on the 23rd, 24th, and 25th February last.

The Society is not one of those which makes a great stir in the world; nevertheless, in the management of its annual Exhibitions, there are many points which might be studied with advantage by other societies holding exhibitions, which are accounted of far greater importance. In the first place, it has never been found necessary to offer medals, or awards of any description, in order to induce members to exhibit. This shows an admirable *esprit-de-corps*, and it also shows that there is little ground for the supposition that, in order to make an exhibition a success, it is necessary to cater for the "pot hunters." Then, the errors which we are obliged to point out in one year's exhibition are not forgotten, but are avoided as far as possible in the next, and there is ample evidence in other things that those who are responsible from year to year for the organization, management, and arrangement of the exhibition, work well together and for the common interests.

On entering the gallery we were favourably impressed with its general appearance. The improvement we found to be partly due to the less crowded state of the walls, for this year the Society has depended more upon its own members, and has been able to all but dispense with the usual loan collection, and partly to the absence of frames of startling hues, which we have had occasion to deprecate in former years. There was a slight decrease, numerically, in the members' pictures, but the average size had considerably increased. The pictures were tastefully arranged, the extra room at command allowing them to be opened out.

Although the average quality of the work was undoubtedly higher, the improvement seemed to be due rather to a levelling up from the bottom than to any striking improvement in the older workers, but that is the usual comment on this season's Exhibition.

Mr. H. J. Spencer had a fine series of pictures all worthy of notice. We may particularly mention *Silver Birches*, *Washing Day at Gurinperlé*, and *Over Stony Ways*. Mr. F. W. Maehen had a charming moorland study, *Amid the Misty Wood*, though its extremely cool grey tone struck us as less pleasing than a warmer colour might be, and his other pictures were good.

In Architectural work we were glad to see Mr. J. B. Panting again exhibiting. We missed him last year. The interiors of St. Saviour's, Southwark, printed in carbon, were all fine, and we can equally bestow praise on Mr. W. H. Dawson. We preferred *From Transept to Choir*, *Winchester*. Mr. C. Churchill had also commendable work, though, in his bromide prints especially, there is a tendency to hardness and want of depth. Mr. J. Hope's *Playmates*, a little girl and a big dog, was good photography, but quite conventional in treatment. In his portrait of a little girl he had quite missed a very good thing. It wanted trimming down considerably. Mr. G. Japp has very much improved in technical photography. Of his four well-chosen subjects we prefer *After the Shower*. Mr. C. H. Imrie's *The College, Cobham, Kent*, made a very pretty little picture.

Figure studies were not numerous. Mr. R. J. Redding's *Ready for Mischief* was unconventional and had plenty of "go" in it. In *A Morning Bath*, a frame which included some dozen or so little pictures of a child in a bath, as varied as attitude and expression could make the same subject. Mr. A. J. Allen scored a distinct success, and his landscapes were good. Other members who deserve notice were Messrs. J. Desforges, M. Gottfried, A. Ames, and S. Hughendon.

The small loan collection consisted of works by Messrs. J. Mummery, H. Stuart, and J. B. B. Wellington. The lantern slides were, perhaps, of not so good an average as last year's. The trade exhibitors were Messrs. Barron & Wellcome, J. J. Griffin & Sons, and Mr. A. J. Wing, a local dealer. As usual there was a lantern entertainment and concert on each evening the Exhibition was open.

#### NORWICH LADIES' CAMERA CLUB EXHIBITION.

THE Ladies' Camera Club, which was formed in 1896, made its *début* before the public of Norwich last week, when the result of the work of its members during the last twelve months was placed on view in the room of the Woodpeckers, in Exchange-street. The Club is a small and select institution, comprising only fourteen members, of whom five are honorary, and the 800 odd pictures which adorn the walls are the work of the remaining nine. That so many views should be hung says much for the industry of the nine, and the great merit of them is eloquent of their ability. This is really the third Exhibition this enterprising Club has held, but the two previous ones, which took place at Carrow Abbey,

were private, and the reason for making the present public is probably to be found in the fact that the members desire to aid the funds of the Jenny Lind Infirmary, for not only is the money taken for admission to be given to that admirable institution, but whatever may be realised by the sale of any of the pictures is to be devoted to the same good purpose. Many of the photographs were taken during the summer outings of the Club, which included a wherry trip on the Norfolk Broads; but they are by no means confined to local views. There are landscapes, seascapes, pictures of flowers, of buildings (interiors as well as exteriors), and of persons, although the latter are few in number. Many of the pictures are enlargements and most of them are very tastefully framed. It is a rule of the Club that the members shall not delegate any of the work to others, professionals for instance; otherwise it would be difficult to believe that amateurs were capable of producing such highly meritorious results. There are many pictures in which very beautiful effects have been obtained, and the carbon work is in all cases excellent. The cloud effects and the appearance of night have been produced with a remarkable degree of perfection, and, indeed, Mr. Percy Lund, the Editor of the *Junior Photographer*, who judged the pictures, declares that it is the best Exhibition of the kind he has ever seen in the provinces, while it is the only one that has been given by a ladies' club. Mr. Lund made a careful inspection of the pictures, and selected nine by three of the ladies as the best in the whole collection. They were as under:—By Mrs. E. T. Boardman: *Narcissus, Cherry Blossom, and Boats on the Nile*. By Miss Edith L. Willis: *By the North Sea; Tom, Tom, the Piper's Son, and Twilight*. By Miss Willis: *Dutch Fishing Boats, Lake of Thun by Moonlight, and A Norfolk Landscape*. These three ladies will receive prizes, and between them will hold a silver teapot, which was to have been awarded for the best collection, but the Judge declared that they were all of equal merit.

#### THE HASTINGS EXHIBITION.

It is some nine years since the Hastings and St. Leonards Photographic Society held their last Photographic Exhibition, and local photographers therefore had looked forward with considerable interest to that held, under the auspices of the Society, at the Public Hall last week. There were about 100 exhibitors, with about 500 exhibits, including several from America, and they were displayed in the Hall so as to appear to every advantage, thanks to the efforts of the energetic Secretary, Mr. A. Brooker. Besides those sent for competition, there were some fifty photographs lent by the Royal Photographic Society (Affiliation Loan Collection), which were ranged below the platform, while at the other end of the Hall there was a collection of cameras and different kinds of apparatus. Very general satisfaction was given by the way in which the Judges whose services the Photographic Society had secured performed their duties—Mr. Wilson and Viscount Maitland, who were assisted by the Duke of Newcastle. There were six classes in which medals were awarded by the Society, and two in which the Hastings and St. Leonards Borough Association offered prizes. The two latter classes were for lantern slides and photographs or art sketches, illustrative of Hastings, St. Leonards, and neighbourhood, and their object was to obtain a collection of lantern slides and a series of post cards for the purpose of making widely known the attractions of the town and district. In this section of the Exhibition Councillor Dr. Gray, Councillor Boutwood, and Mr. R. White Ford (the Chairman of the Borough Association) acted as Judges, but the exhibits hardly came up to expectations. There were but few entries for lantern slides, and the first prize, which was to have been given by the President of the Photographic Society, was not awarded. The second prize was three guineas, which was obtained by Mr. W. A. Thomas, with an admirable set of slides, representing scenes well known to Hastingsers, such as Battle Abbey, Hastings Castle, the Pier, several views of the Parade and the Old Town, and of the Beach. Mr. Joshua Smith was awarded third prize (two guineas) for a similar set, noteworthy among which were a couple of views of Eversfield-place and Grand-parade, St. Leonards, a rough sea at St. Leonards, the Baths Promenade, the Alexandria Park, and Old London-road.

At the opening ceremony the Mayor said that the Exhibition was held at an opportune time. In the closing years of the present century rapid strides had been made in every branch of science, but in none more so than in the photographic art. It was his duty to declare the Exhibition open, and he would also, in the name of the Photographic Society, and in the name of the town, thank Mr. Wilson Noble and Lord Maitland for the assistance they had given in acting as Judges on that occasion, and also the Duke of Newcastle for his services.

Mr. Wilson Noble, in returning thanks, said that it had been a very great pleasure for them to come down to that Exhibition, and they had felt it an honour to act as Judges. They had had the opportunity which, perhaps, would not be the case with all who visited that Exhibition, of examining carefully all the exhibits, and he could safely say, and he was sure Lord Maitland would agree with him, that the Exhibition was a very marked success. He remembered being present at a similar Exhibition in that room some years ago, which was considered to be successful, but the present Exhibition far eclipsed the former, both in technical and pictorial excellence. It was always

difficult for Judges to decide whether they should pay most attention to the technical or the pictorial side, but he (the speaker) believed in the latter, as technical excellence was only a means to an end, the final result being the thing to be looked to. Taking the Exhibition as a whole, the Society were to be heartily congratulated on it as a considerable success.

The Judges' awards were as follows:—

Class A.—Gold medal withheld; silver medals, No. 65, Mr. J. E. Dumont; No. 70, Mr. C. Job.

Class B.—Silver medal, No. 115, Mr. C. Job; bronze medal, No. 91, Mr. W. D. Welford.

Class C.—Silver medal, No. 144, Mr. James Rooth; bronze medal, No. 148, Miss M. Weil.

Class D.—Silver medal, No. 212, Mr. E. R. Bull; bronze medal, No. 214, Mr. A. J. Loughton.

Class E.—Silver medal, No. 261, Mr. W. F. Ward; bronze medals, No. 242, Mr. E. G. Boon; No. 263, Mr. G. H. Capper.

Class F.—Silver medal, Nos. 315 to 320, Mr. G. Bird; bronze medal, Nos. 306 to 311, Mr. E. Marriage.

Class G.—Silver medal withheld; bronze medal, No. 345, Mr. T. H. Redwood.

Class H.—Silver medal, No. 383, Mr. J. Smith; bronze medal, No. 366, Mr. C. W. Kennaway.

#### THE BIRMINGHAM EXHIBITION.

A VISIT to the Fourteenth Annual Exhibition of the Birmingham Photographic Society, which is being held this week in the galleries of the Royal Society of Artists, enables us not merely to note the great advances which photography in its pictorial aspect has made during the last three or four years, but also the forward strides which the Society itself has taken in promoting and holding a representative Exhibition of modern work. It is four or five years since we personally examined a Birmingham Photographic Exhibition. At the time we speak of, the display was held in the well-remembered Hall in Needles Abbey, lit, if we do not mistake, entirely from one side. The apartment was far too small for the purpose, and consequently very easily became crowded. A minute and confusing classification was in vogue, and the newer methods of framing and printing had not yet taken hold to an appreciable extent of those who sent in contributions to the Exhibition.

All this seems only as yesterday, and what a revolutionary change has apparently taken place since then! The great room of the Royal Society's galleries is an ideal apartment for hanging pictures in. It is of circular form; the light comes from the top of the dome. The walls, covered with a light green fabric, and draped at intervals with a darker variety, bear some hundreds of excellent photographs, which are viewed under the best possible conditions of lighting, surroundings, and hanging. Truly the Birmingham Society are greatly to be envied for the fine environment they are enabled to give their Exhibition, which could not be held under more favourable circumstances. Several smaller halls spring from the main rooms, and these have been utilised to the best advantage in sheltering individual collections of work and portions of the Exhibition.

This year the classification has been brought down to simple limits. The classes consist only of Open, a Loan Collection, Members' Survey, Lantern Slides. The Judges were Messrs. A. Horsley Hinton, John H. Gear, F.R.P.S., and W. J. Wainwright, A.R.W.S. In all, considerably over 500 photographs were hung, and the Lantern-slide Class attracted twenty-one competitors, who sent in sets of six or more. Amongst Birmingham professional photographers the following sent in special exhibits, contained in separate rooms: Messrs. Harold Baker, 58, New-street; J. W. Beaufort, Colmore-row; J. A. Draycott, New-street; H. J. Whitlock, New-street and Broad-street. The North Room was devoted to an exhibition in novelties in apparatus and appliances, by the following firms: Messrs. Morris Banks & Co., Bull-ring; C. S. Baynton, Exchange-buildings, New-street; Griffiths & Co., Union-passage and Highgate-square; Southall Brothers & Barclay, 1, Broad-street; W. Tylar, High-street, Aston; Birmingham Mutoscope Company, Limited; J. J. Griffin & Sons, "Velox," London; F. Lewis, 16, Gladstone-road, Sparkbrook; Harcourt, Fox, & Co., County Chambers, Corporation-street.

The Open Class, containing 156 exhibits, was an exceptionally strong one, and the Judges must have had a rough time in coming to their decisions. It struck us that the imitative tendency into which certain exhibitors have recently fallen was very strongly apparent. For instance, to take an example which we noted as we passed over the exhibits, Mr. C. T. Humphrey's *Wet Night—Dalston-lane* was highly suggestive of Mr. Paul Martin's *Clapham Pavement*. Mr. H. C. Leat's *Winter and October* are full of realistic wintry effect, and one of the most charming little views of a yacht race we have seen comes from Mr. W. T. Greatbach in No. 46, *The Race*. The same exhibitor's landscape photographs are undeniably good. Mr. G. J. T. Walford may be advised not to follow too closely the style and methods of Mr. A. Horsley Hinton, who has several other imitators and copiers in this Exhibition. We think that executives should take note of this sort of thing. The portraits were exceptionally fine, Mr. J. A. Draycott particularly distinguish-

ing himself with some good work. On the other hand, Mr. Geckle's *Study of a Child's Head* looks uncommonly like one of Mr. Harold Baker's *Geoffrey*, we think it is called, and in Mr. Charles Speight's *Portrait of a Lady* we seem to see Mr. William Crooke's *Lady Mary Lygon* over again. Doubtless the force of example is very strong in photography, but, where imitation is carried so far as to amount to copying, we think a protest is called for.

Mr. C. S. Baynton strikes new ground this year, and some of his figure studies are so extremely good that we are justified in looking for really great things from him in the immediate future. He has a fine eye for a gracefully posed figure having the attitude and movement of life, but at present he is not quite sure of his powers, and therefore falls into the easily remedied defect of overcrowding his canvas, so to speak, thus detracting from simplicity of effect, which is the highest result to aim at. Mr. Pirie Macdonald's portraits of *Mistress Dorothy* and *Miss Annie C.* stand out by reason of the striking power shown in the posing and lighting. We wish we could see more of the work of this exhibitor, who is a leading professional in the States. On the whole, if we make allowance for the imitative tendency we have already referred to, the portraiture comes out very strongly. One of Mr. Draycott's exhibits, the head of a lady in profile (No. 113), we seem to have seen before. It is uncommonly like a similar subject shown years ago by Mr. Percy Lankester. Other pictures of high merit are Mr. F. Howard Mercer's *Buoy repairing, Brizham*; Mr. Smedley Aston's rustic studies, Nos. 16 and 17; Mr. W. A. Fraser's view of *Fifth Avenue (N.Y.) in Winter*; Mr. Ernest Marriage's well-chosen, carefully exposed little architectural bit, *An Old Belfry*; Mr. Thomas Carter's clever hand-camera studies (No. 85); Miss Boden's group of lady and children (No. 129); and Dumont's always welcome *Village Choir*. The architectural studies are not numerous, but are a remarkably level series, C. S. Baynton, Harold Holcroft, W. R. Bland, and J. H. Gash sending in very good work.

The Loan Collection, numbering over a hundred examples, makes a fine exhibition in itself. Familiar work comes from Messrs. A. Keighley (Mr. Keighley's studies have a curiously old-fashioned effect in our eyes, they would have been accounted very great a few years ago, but now seem to suffer from over-elaboration of detail), Sweet, Warneke, Harold Baker, A. Horsley Hinton, H. W. Bennett, W. J. Warren (amongst Mr. Warren's series are some delightful studies of a little girl who readily lends herself to ideal treatment by the lens), E. R. Ashton, W. Crooke, J. Stuart Bhedwar, Rejlander, Lund, Karl Greger, J. Craig Annan, Sutcliffe, Thomas, and others.

In the Members' Section the experienced hand of Mr. Ernest Underwood is responsible for several admirable views at Wells Cathedral and Oxford, and bold in effect is Mr. Francis A. Bolton's *Scotch Firs*. *Reedy Wastes*, by Mr. W. Smedley Aston, shows how easily Mr. Hinton may be imitated. *A Blast Furnace*, with its yellow effect of light, is a clever rendering of the subject. *Awaiting Evening Tide*, a marine study by Mr. A. C. Peach, attracted attention, and Dr. Hall-Edwards has a capital bit of technique in *In the Workshop*. *Sweet Seventeen*, by Mr. Aston, a delightful study of a young lady, simple and unconstrained in the pose, and softly lit, we highly admired at Bradford. It is the best thing we have seen from Mr. Aston's hands. Capital views by Professor Allen (President) and Mr. George Whitehouse are shown in the class, to which notable contributors besides those named are Messrs. Hugh Lewis, H. J. Yeates, and William Topham. The work shown by the members of the Birmingham Society is really so good that a first-rate exhibition could very easily be organized without outside aid.

In connexion with the Warwickshire Survey some fifty photographs are hung, and Dr. Hall-Edwards, one of the most noted radiographers of the time, has half a dozen interesting studies.

Great pressure on our space obliges us to very much abbreviate our notes on this Exhibition. Very little work was hung that could be objected to on the score of quality, and the Open Class is a singularly level display. But among these photographs the imitations are so palpable that we feel it a duty to call the attention of Exhibition executives to the matter. We have only noticed this tendency during the last year or so, and it should seriously be considered how far it should be countenanced or encouraged.

#### A WIFE'S PHOTOGRAPHS—"NECESSARIES."

JUDGE STONER delivered judgment, on February 24, at Marylebone County Court, in a case in which a photographer, Mr. Hayman Seleg Mendelssohn, Pembroke-crescent, Bayswater, was the plaintiff, and the defendants, the Hon. D'Arcy Lambton and his wife, of Gordon Mansions, W. Mr. Lowe was counsel for the plaintiff; Mr. Shearman represented Mr. Lambton, and Mr. Chapman appeared for Mrs. Lambton. His Honour said the plaintiff sued the defendant for 29l. 18s. 6d., for photographs and a miniature, the cost of the latter being 10l. 10s. The photographs and miniature were portraits of the wife, and, the plaintiff alleged, were ordered by her with her husband's authority. The order, sale, delivery, and prices were admitted, but Mr. Lambton denied that his wife had any such authority. Mr. Lambton, formerly a lieutenant in the Royal Navy, married the co-defendant in 1888. He then had a fortune producing

about 1000l. a year, while his wife had none. In 1892 Mr. Lambton settled a large account for his wife's photographs. About this time she told him that she had recently got from her grandmother in Australia an allowance of 400l. a year, and it was then agreed that for the future she should pay her own personal expenses. The husband continued, however, to pay large sums for her personal debts. In 1897 he absolutely refused to pay these personal debts for her, and next year they separated, he formally prohibiting her from pledging his credit. It was about this time that he learnt that his wife never had a settled allowance, although she had received from friends gambling at Monte Carlo, and from other sources, some 200l. or 300l. a year. Upon the whole, considering that Mr. Lambton had paid about 10l. a year for three years on account of his wife's photographs, apparently recognising them as "necessaries," he (the Judge) thought the case resolved itself into a question of excess of authority. He found that Mr. Lambton was liable for 10l. 10s., and that the co-defendant, Mrs. Lambton, must be held to have pledged her personal estate for the goods absolutely or conditionally, in case her husband refused to pay. He, therefore, found against her for the balance, 19l. 8s., with costs.

## Our Editorial Table.

### THE "SANDERSON POPULAR" CAMERA SET.

George Houghton & Son, 88 and 89, High Holborn.

THE Sanderson Popular Camera, although introduced at popular prices, has all the features and advantages of the more expensive form. A few of the points claimed for the camera are that it has a greater rise of front than is obtainable with any other. It does away with the tilting of the camera, entirely dispenses with the swing back, and, in place of all the old movements and adjustments of camera and stand, a greater latitude between lens and plate is secured, with the power to swing the front and

to compose a subject on the ground glass and roughly focus it, all by one and the same action; it is controlled by two adjusting screws only, one on either side of the camera front.

The Sanderson Popular Camera Set comprises a camera with wide-angle movement, special long extension (half-plate, twenty inches), &c.; double dark (book-form) slide; rapid rectilinear achromatic lens with iris diaphragms; Thornton-Pickard time and instantaneous shutter; three-fold tripod stand.

### ARMSTRONG'S GUIDE TO PRACTICAL PHOTOGRAPHY.

By T. N. ARMSTRONG. 142 pp. Price 1s.

London: Dawbarn & Ward, 6, Farringdon Avenue, E.C.

READERS of this JOURNAL have for many years been familiar with the numerous practical articles which Mr. Armstrong has contributed to its pages. His advice is the outcome of mature experience, and can always be relied upon. In the closely printed volume before us he devotes some thirty-nine chapters to his subject, to most of the ordinary branches of which he introduces the reader. It is difficult to select any one part of the book for special mention when the whole of it bears the impress of a master hand; suffice it to say that it is written very exhaustively throughout, and that it may be recommended as a safe guide to place in the hands of a beginner. There is much wisdom in the concluding sentence of the chapter on apparatus: "The requirements of a good photographic outfit are not many, and need not be unnecessarily expensive, to produce excellent all-round work."

## THE FRENA PNEUMATIC RELEASE.

R. &amp; J. Beck, Ltd., 68, Cornhill, E.C.

THIS attachment consists of an indiarubber ball and tube acting upon a spring plunger. Squeezing the ball pushes in the shutter release and sets off the shutter, thus making the exposure. To attach it, two screws are screwed into the camera, as shown in the figure, and the apparatus can be clipped on or taken off as required without removing the screws.

The advantages of the release are, that it overcomes the risk of shaking the camera in the act of setting off the shutter; that it enables an exposure to be made in many positions where it is otherwise most inconvenient to get at the shutter set off. It is pointed out that with a long tube and large ball the operator may retire to a position at a distance from the camera and make the exposure unobserved; he may also take his own portrait or may form part of a group.

## ADUROL.

Agents, A. &amp; M. Zimmermann, St. Mary-at-Hill, E.C.

ADUROL is a new photographic developer, said to be obtained from hydroquinone by a patented process. It is sent out in the form of a fine greyish-white powder, and among the advantages claimed for it are that the image is seen in about a third of the time taken by hydroquinone to produce an appearance; greater detail and strength of half-tone are obtainable; the total time necessary to complete development is shorter; no stain results; and the solution may be used over and over again. It has also been ascertained "that two parts by weight of adurol, with a like amount of an alkaline carbonate and sulphite, develop in the same time a more vigorous negative than three parts by weight of hydroquinone." Adurol, therefore, obviously has features of a distinctive character to recommend it to the notice of photographers.

## THE VICTOR FIXING SALT.

Agents, Fuerst Brothers, 17, Philpot-lane, E.C.

THIS is a new preparation of Messrs. Lumiere's, the hyposulphite being sent out in the form of an anhydrous acid compound. Among the advantages claimed for using the salt in its converted form is that it dissolves instantaneously in water: Although the weight is about two times less than hypo, it contains the same quantity of active substance. On account of the acid reaction a great number of negatives can be fixed without discolouring the solution, even if the negatives have been insufficiently washed after development. It becomes possible, when using this salt, to fix plates and papers without washing them after development. It slightly hardens the gelatine. The following is the bath recommended for plates and papers:—

Water .....	1000 grammes, or say 25 ounces fluid.
Victor fixing salt.....	80 " " 2 ounces weight.

## THE VANGUARD ACID-PROOF NEGATIVE VARNISH.

Manufactured by the Vanguard Manufacturing Company, Maidenhead.

WE can cordially recommend this preparation as a sure preventive of stains on negatives. Applied either hot or cold, it dries very quickly, and thereafter interposes a practically impenetrable and impervious film between the silver image and external influences. We have subjected negatives coated with the Vanguard acid-proof varnish to a number of very severe tests, and have found that it acts as a perfect protector of the image. Negatives covered with this varnish are, in the ordinary course of things, absolutely secure from chemical attack. Photographers will find a supply of the varnish one of the best investments they can make for the negative room.

MESSRS. ELLIOTT & SON, of Barnet, send us an advanced copy of a new edition of their bi-monthly journal, *The Photographers' Record*. Dealers who have not hitherto had supplies can be furnished upon application for free distribution. *The Record* in its new get-up presents a very tasteful and artistic appearance. The contributions by Mr. Bothamley and Mr. Land, on "Development" and "Impressionism," are useful and readable.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, March 8, at eight o'clock. Members' Open Night.

G.E.R. MECHANICS INSTITUTION (PHOTOGRAPHIC SECTION).—Photographs for the Open Class of this Exhibition will be received up to March 13, instead of 11th, as already announced.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday next, March 9, at eight o'clock, Mr. A. T. Harris will read a paper, "A Chat on Photographic Lenses." The meetings are always open to visitors, who require no card of invitation.

MESSRS. TRENEBY & COPE, carbon, platinum and silver printers, of 147, Prescott-road, Fairfield, Liverpool, have dissolved partnership. Mr. W. Cope has taken over the business, which will in future be carried on by him under the style of W. Cope & Co.

CRIPPLEGATE PHOTOGRAPHIC SOCIETY.—The next meeting of this Society will be held on Monday, March 6, at the Cripplegate Institute, and will take the form of a Lantern Night. Intending members are invited to make application for full particulars to the Hon. Secretary, Mr. Alfred T. Ward, Cripplegate Institute, Golden-lane, E.C.

BIRMINGHAM INDUSTRIAL EXHIBITION.—We are asked to remind readers that for the photographic section of this exhibition entries close Monday next, March 6; London exhibits must reach Mr. Welford's office by Wednesday next, 8th inst., and all other exhibits (except those from the South London Exhibition) must reach Bingley Hall by Saturday, 11th inst.

THE Fifth Annual Dinner of the Hackney Photographic Society was held on Tuesday evening, February 28, at the London Tavern, Fenchurch-street, E.C. Mr. Edward Puttock (President) occupied the chair, and he was supported by about sixty members and visitors. A feature of the evening was the presentation to Mr. W. F. Fenton-Jones (the retiring Hon. Secretary) of a handsome diamond ring, subscribed for by members in recognition of his services to the Society since its foundation ten years ago. The presentation was made by Mr. Herbert Robertson, M.P. The toasts included "The Society," "The Visitors," and "The President," and, as usual at the Hackney dinner, that portion of the programme prepared for the amusement of the company contained a number of capital items capitally rendered. The dinner was a very great success throughout.

THE ADOPTION OF THE METRIC WEIGHTS AND MEASURES.—At a meeting of the Manchester and Salford Trades Council held on the 16th ult., the following resolution was passed:—"That this Council desires to again express its sympathy with the objects of the Decimal Association, believing that by their adoption the interests of commerce and industry throughout the United Kingdom will be much benefited." All the leading Trades Unions in Great Britain strongly support the movement for the adoption of the metric weights and measures by this country, and on two occasions at the Congress of Trades Unions resolutions in favour of this reform were unanimously passed. It appears from the resolution passed at Manchester last week that these trade organizations intend to agitate with fresh vigour for legislation to render the metric weights and measures compulsory.

THE movement for preventing the destruction by the builder of Croydon Hurst, Croydon, is rapidly gathering increased energy. The secretary of the Preservation Committee has received a large amount of correspondence from all parts of the country, showing the widespread interest in the project for acquiring the whole of the hill for the public for ever. The Committee, some seventy-five strong, met the Croydon Council on Monday last as a deputation, urging them to push forward the inquiries they have in hand to obtain the price for the remaining fifty acres from the Whitgift governors. Under present arrangements nothing is likely to be done for some time to come unless in response to a definite demand by public opinion. A mass meeting will be held at the large public hall, Croydon, on March 10, when resolutions in favour of acquiring the whole of the Hurst on favourable terms will be submitted. Representatives will be present from the Croydon Council, the Rural District Council, Microscopical Society, the National Trust, Selborne Society, Commons Preservation Society, Croydon Guardians, School Board, Camera Club, Chamber of Commerce, &c. A series of lantern slides illustrating the Hurst is in preparation by Mr. Hector Maclean, which will be shown at numerous local meetings which will follow the mass meetings.

A PROFESSIONAL'S LECTURE TO AMATEUR PHOTOGRAPHERS.—On Thursday evening, February 22, Mr. F. Fielding delivered a lecture to amateur photographers at the studio of Messrs. Fielding & Jepson, Mincing-lane, Blackbarn. The subject of the lecture was "Carbon Printing," and Mr. Fielding illustrated his remarks by practical demonstration. He explained the necessity of printing by means of an actinometer, and went through the process of developing several carbon tissues, showing how they may be transferred on to opal, glass, &c. The lecture was made additionally interesting by the fact that any one was allowed to develop tissues himself in order that the process might be better understood. Mr. Fielding pointed out the great simplicity of the working of this process as compared with the P.O.P. process, and added, that not only was it much cheaper but less time was wasted than in the working of silver paper. The results of the carbon process could scarcely be compared with the silver paper for beauty, whilst any number of tints, ranging from dark blue, sea green, purple black, sepia, terra cotta, &c., could be obtained. The prints also, unlike most silver paper, were absolutely permanent, time and wear having scarcely any effect upon them. Several specimens taken on carbon were exhibited, and a most pleasant evening was spent. At the close a vote of thanks was passed to Mr. Fielding for his interesting and instructive lecture, and Mr. Fielding, in replying, remarked that he was pleased to do all he could to help any amateur. To read about carbon printing in a book, he said, was like learning to swim by reading. They wanted to see it done practically, and to try it themselves, before the simplicity of the process could be realised.

## Patent News.

THE following applications for Patents were made between February 13 and February 18, 1899:—

- CAMERAS.**—No. 3194. "Improvements in Photographic Cameras." M. NIELL.  
**DARK SLIDES.**—No. 3257. "Improvements in or relating to Photographic Dark Slides or the like." H. FARMER.  
**BACKING TRAY.**—No. 3262. "Photographic Plate Backing Tray." J. H. AVERY and C. VARNAM.  
**STEREOSCOPIC APPARATUS.**—No. 3274. "Improvements relating to Coin-freed and Stereoscopic Apparatus." Communicated by E. HANAN and E. GAUTHIER. A. F. SPOONER.  
**KINETOSCOPIC PICTURES.**—No. 3285. "Improvements in and in Means or Apparatus for Producing and Exhibiting Kinetoscopic and like Pictures." H. A. BROWN.  
**FILMS.**—No. 3419. "Improvements in Photographic Films and in Apparatus for Using same and connected therewith." J. E. THORNTON.  
**LIGHT-FILTERS.**—No. 3492. "Improvements in and relating to Translucent Screens or Light-filters for Use in Photography." H. FARMER.  
**COLOUR PHOTOGRAPHY.**—No. 3560. "Improvements in Colour Photography." W. N. L. DAVIDSON.  
**CHANGING BOXES.**—No. 3582. "Improvements in Photographic Changing Boxes." H. WOOD.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
6.....	Barnet and District .....	P.O.P. Demonstration. W. H. Harrison.
6.....	Beverley .....	Bells and Bell-ringing. The President.
6.....	Bradford Photo. Society .....	Members' Slides, Prints, &c.
6, 7 .....	Camera Club .....	Exhibition of Novelties.
6.....	Kingston-on-Thames .....	{ Apparatus for Animated Photography. Birt Acres
6.....	Putney .....	{ Lighting and Exposure. Francis T. Beeson, F.R.P.S.
6.....	Richmond .....	Affiliation Slides, B Set.
7.....	Ashton-under-Lyne.....	Venetian Pictures. James Shaw.
7.....	Birmingham Photo. Society ..	{ Display of Lantern Slides sent in for Competition at the Annual Exhibition.
7.....	Gospel Oak .....	{ Exhibition of Members' Work and Social Evening.
7.....	Hackney .....	Annual Meeting.
7.....	Iale of Thanet .....	Lantern Slides. John A. Hodges.
7.....	Lewisham .....	Development Competition by Members.
7.....	Rotherham .....	Architectural Photography. J. H. Avery.
8.....	Croydon Camera Club .....	Lantern Night.
8.....	Leeds Camera Club .....	Crysoleum. J. Skilbeck.
8.....	Photographic Club .....	Members' Open Night.
8.....	Southport .....	Three colour Photography. Henry Ball.
9.....	Camera Club.....	{ Possibilities of Electric-power Supply in England. Leonard Addenbrooke, M.I.E.E.
9.....	Darwen .....	Flashlight Evening.
9.....	Liverpool Amateur.....	{ X Rays Up to Date. Dr. C. Thurstan Holland.
9.....	London and Provincial .....	{ A Chat on Photographic Lenses. A. T. Harris.
9.....	Oldham .....	My Camera and I on the Antrim Coast. J. W. Cooper.
9.....	Woolwich Photo. Society .....	Slides contributed by Affiliated Societies, Set A.
10.....	Croydon Microscopical .....	Channel Islands, Norfolk Broads, and Lake District Slides. A. P. Hoole.
11.....	Croydon Camera Club .....	Forty-first Public Lantern Show.

### ROYAL PHOTOGRAPHIC SOCIETY.

FEBRUARY 28,—Technical Meeting, Mr. J. J. Vezey in the chair.

#### APPARATUS FOR ANIMATED PHOTOGRAPHY.

Mr. BIRT ACRES read a paper on the above subject, and described and demonstrated the Birtac, his apparatus for taking and exhibiting animated photographs. Having recalled the fact that he was the first to show such pictures on the screen in England, when, some three years ago, he gave an exhibition at a meeting of the Society, he proceeded to give a brief historical sketch of the history and development of this branch of photography, which he considered would be the photography of the future. Starting with the old "wheel of life," or Zoetrope, he alluded to the work of Professor Muybridge, who used a series of cameras for taking the negative; Mr. Friese Greene, who made the first serious attempt to take a series of pictures on a continuous band of sensitised material; Professor Anschütz; M. Demeny; MM. Lumière; and M. Marey; and also referred to the Edison Kinetoscope and the Biograph and Mutoscope, discussing the advantages and disadvantages of the various forms of apparatus which had from time to time been introduced. Mr. Birt Acres' latest instrument for "at home" animated photography, the Birtac, has already been described in these pages, and it is unnecessary to refer in detail to its construction; it is sufficient to say that it is a small but very complete and practicable apparatus, which is sold at a comparatively low price, and that by simply altering the position of the lens it can be used either for taking the negatives or exhibiting the transparencies, a film twenty feet in length being employed, containing 640 pictures, each half an inch by three-eighths of an inch, the whole being projected in about a minute. The apparatus is fitted for use with incandescent gaslight as the

illuminant, and Mr. Acres showed his very ingenious and effective method of increasing the pressure of the gas, by means of which he is able to obtain a well-illuminated disc of five feet diameter. The pictures shown at the conclusion of the paper were projected upon a screen of ground glass about two feet square.

At the close of the exhibition, Mr. CHAPMAN JONES, while recognising the improvement effected by the increase of gas pressure, suggested that, having regard to the fragile nature of the incandescent mantles, it might be advantageous to adopt acetylene as the illuminant.

Mr. BIRT ACRES replied that he did not yet know enough about acetylene to justify him in putting a lamp upon the market, and the restrictions of the London County Council and other authorities made him doubt the wisdom of adopting such a course.

Mr. DANDO dissented from an opinion which had been expressed by Mr. Acres in favour of perforating the films at the margin rather than between the pictures.

Mr. ACRES said that, although by the latter method the whole width of the film could be utilised for the negatives, it was then necessary to waste a space between each two pictures, as by continual use small portions of the film were split off, and the negatives were spoiled unless the perforations were made upon the blank spaces between them.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 23,—Mr. S. Herbert Fry in the chair.

The HON. SECRETARY read a communication he had received from Mr. A. L. Henderson, touching the matter discussed in Mr. Howard Farmer's recent paper before the Association upon the light in the dark room. He had little doubt that many of the members would remember that some years ago he offered a prize to any one who would devise a safe light. Although his offer remained open for a long time, not a single candidate came forward until, some years after the withdrawal of his offer, he received a communication from a very clever Scotch photographer on the subject. This man offered the following suggestion in the hopes of securing the award, viz., to pass the light through a number of pinholes and then reflect it into the dark room. This idea was, however, found wanting upon examination. Mr. Henderson proceeded to describe some experiments which he had undertaken at that time. Dr. Gladstone, at a meeting of the British Association, exhibited some photographs showing the peculiar property of a solution of disulphate of quinine. One of the Doctor's experiments was repeated by Mr. Henderson before the Association. Three wine glasses were arranged side by side, containing water, black ink, and a nearly colourless solution of disulphate of quinine respectively. The three were photographed together, and it was found impossible to distinguish any difference between the photograph of the vessel containing the ink and that containing the solution of quinine. It was suggested at the time that a cell of such a solution of quinine disulphate should be used in lieu of coloured glass for dark-room illumination, and Mr. Henderson had a lantern constructed for the use of such cells. The arrangement was useful experimentally, but was not found effective. Another of his ideas was to use light reflected from luminous calcium sulphide (Balmann's paint), both plain and filtered through coloured media; the light so obtained was very feeble and consequently fairly safe. Some advantage was also obtained by using a reflector of orange paper saturated with a solution of disulphate of quinine. Mr. Henderson has predicted that the day will come when it will be possible to prepare very sensitive plates in a white, or nearly so, light—in other words, to separate the actinic rays. Perhaps a judicious arrangement of coloured screens and sensitisers might lead to the desired result. Mr. Henderson also commented upon the opinion expressed by Dr. E. Vogel that the action which took place in formate toning was a depositing action and not a substitution process. Had this been the case, Mr. Henderson could have seen a great future before it, as richer prints might have been obtained from weak negatives. He did not agree with him, however, and sent some prints marked one and two to support this. Each print was cut in half and toned separately, one with formate and the other *minus* formate, and it was impossible to distinguish between them. A vote of thanks was passed to Mr. Henderson.

The CHAIRMAN showed five or six stereoscopic transparencies interesting as made by his father in 1857, in the wet-collodion days. They were instantaneous studies of waves, and spoke well for the processes of those early days. It was stated that the positives were made and sold to houses like Horne and Thornthwaite, at the wholesale price of a guinea a piece.

Mr. P. R. SALMON gave a brief account of his experiences in the Holy Land as a photographer, and showed about a hundred slides made from the negatives taken during his journey. His encounters with the Customs authorities, soldiery, &c., and the insight afforded the meeting into the powers of judiciously distributed "backsheesh" were of an entertaining character, and admiration for his photographs was freely expressed.

The Chairman supplemented the lantern display with some very fine slides from some of Rejlander's original studies from the nude, which met with every mark of appreciation.

### PHOTOGRAPHIC CLUB.

FEBRUARY 22.—Mr. Frank Hae in the chair.

Mr. E. W. FOXLEE made reference to the opinion that red tones were impossible upon Velox paper by direct development, expressed at the last meeting. Mr. Ethelbert Henry had said that they could be got, but exposure to daylight was necessary unless one had the patience of Job. Mr. Foxlee thought it might be of interest to show that red tones were quite possible by artificial light with an exposure so short as to induce one to think that Job's patience was much over-rated. He showed a series of prints ranging from red, through red-brown, to sepia, with exposures of three or four seconds with magnesium ribbon, the longest being two inches of ribbon burned five inches from the negative. The negative was an old collodion one, and the developer

Mr. Foxlee promised to give shortly, so soon as he had reduced to a definite formula the information he had gleaned from experiment.

Mr. WALTER D. WELFORD delivered his lantern lecture on the "Cumberland Fells" in that part lying round the old lead-mining district of Alston, the highest market town in the country, situated between Carlisle and Newcastle-on-Tyne. The pictures were such as to show what systematic procedure could do in evolving an entertaining series from a bleak, desolate, and monotonous tract of country such as this, and lecture and slides served to emphasise the views held by the lecturer regarding the unhappy tendency of Society lantern displays to degenerate into a mere procession of slides with nothing in the way of descriptive observations, excepting the make of plate, lens, stop, &c., a state of things which he hoped would not obtain for long.

**Kingston-on-Thames and District Photographic Society.**—February 20.—Mr. A. VANDENDRIESCHE lectured upon

#### ROME AND POMPEII.

After several photos of St. Peter's had been thrown upon the screen the lecturer showed a view of the portico of the Temple Faustina, special interest being attached to this picture by reason of the recent discovery of the spot where Julius Cæsar was cremated. Numerous views of the Colosseum having been passed through the lantern, the lecturer took his audience to Southern Italy, the first picture representing the Bay of Naples with Vesuvius in the background, this being followed by a collection of snap-shots secured in the vicinity of Pompeii. Included in these was a photograph of a typical South Italian team, consisting of a horse, a mule, and an ox. These teams, said the lecturer, often vary considerably in their zoological combination. He remembered, on one occasion, meeting a loaded cart going to market, the proprietor's wife and ass supplying the motive power. Another interesting picture represented the Capuchin monastery, the peculiarity about this building being that the entrance hall is situated on the top floor.

**Liverpool Amateur Photographic Association.**—February 23.—There was a crowded attendance of members and friends present to hear Mr. G. E. THOMPSON'S discourse on

#### THE CANYONS OF SOUTHERN FRANCE.

Mr. Paul Lange (President) occupied the chair. Mr. Thompson in a vivid manner described the remarkable limestone plateaux of the Garonne basin, which is of the greatest interest to ethnologists and geologists. The series of 130 pictures illustrating the course of the rivers Dordogne, Lot, and Tarn revealed scenic wonders, equalling in grandeur the famous canyons of America, and surpassing them in the added interest lent by ancient castles, chateaux, bridges, cottages, caves, and other relics of the mediæval times. The course of the Tarn is especially remarkable, and the lecturer's vivid account of his hazardous descent of its rapids was fitting climax to a bright, well-studied, and most entertaining narrative.

**Plymouth Photographic Society.**—February 24, the President (Mr. H. S. Hill) in the chair.—Mr. HENRY J. HISSSETT gave a lecture and demonstration on

#### PLATINOTYPE.

Mr. Hissett is an esteemed member of the Society, and though by no means an old photographer, his great energy and devotion to photographic art always enables him to accomplish most thoroughly that which he has set his heart on doing, time and expense being but very little considered. This fact is well known to his fellow-members, consequently he was a big "draw," and the large number who came were well rewarded. A full history of the process from the time of its introduction by Mr. Willis, together with the dates and particulars of his many patents, were given, and, with the aid of chemicals, Mr. Hissett, in several experiments, showed the principles involved. His lecture lasted exactly one hour, after which he gave a practical demonstration, developing about forty prints, from whole-plate and half-plate negatives. Taking the glycerine method first, he showed how slow it was possible to make the development, and how easily any particular portion of the print could be strengthened or kept back, also the method of getting good "vignettes." Then, with the developer heated to about 70° in a dish, he performed development at a faster pace, and eventually made several sepia prints, with the hot bath, with almost lightning rapidity, and all without a single failure. A set of prints, trimmed and mounted, duplicates of those developed that evening, were then passed round for inspection. These were the work developed by Mr. Hissett at a meeting of the Devonport Camera Club, where he gave a demonstration four months ago. They were, undoubtedly, very fine, many of them were printed and kindly sent to him for each of his demonstrations by the Platinotype Company, to whom he was much indebted.

**Redhill and District Camera Club.**—February 21.—A short paper was read by Mr. F. MARTIN DUNCAN on

#### CHOOSING A SUBJECT,

the lecturer confining his remarks chiefly to landscape photography. Mr. Duncan illustrated his lecture with photographs, to show the errors and mistakes generally made by the beginner. A discussion followed on the merits and elements of rapid plates in landscape photography, the general opinion being in favour of a plate of medium speed. At a subsequent Committee meeting, it was decided to start a circulating portfolio, to which members of the Club will be invited to contribute specimens of their work.

**Blairgowrie and District Photographic Association.**—At the Annual General Meeting of this Association on Tuesday, a framed photograph, entitled *Woodland Sunshine*, was presented to the Association Gallery by Mr. J. Kearney, jun., Liverpool, for which the Secretary was instructed to thank him. The *Gazetteer of Great Britain and Ireland* (3 vols.) and *Photograms* of 1895-96 97 98 from the President and four members were added to the library. The Secretary and Treasurer's reports were submitted and considered satisfactory, and office-bearers for the season were elected as follows:—*President*: Mr. Alexander Gaskie.—*Vice-Presidents*: Messrs. T. C.

Gorrie and John B. MacLachlan.—*Executive*: Messrs. Petrie, Richardson, Soutar, Mitchell, and Hendry.—*Lanternist*: Mr. H. S. Fyfe.—*Treasurer*: Mr. D. G. Monair.—*Secretary*: Mr. H. B. Jauntson. It was remitted to the executive to prepare a syllabus for the coming season.

**Edinburgh Photographic Society.**—The Exhibition of the Society, which has been open in the Society's Hall, 38, Castle-street, for the last three weeks, was formally closed on Saturday night. There was a crowded attendance, presided over by the President, Mr. A. Eddington, F.I.J. Mr. LANDER THOMSON gave a lecture entitled,

#### A RAMBLE THROUGH FLORENCE,

which was illustrated by numerous lantern slides of excellent quality. The lecturer dealt largely with the architectural and art features of the city, explaining the position which Florence occupied in the world of art, and alluding to the influence of these art treasures on the people. Mr. EDDINGTON, in closing the Exhibition, stated that it was the most successful yet held by the Society in regard to the attendance of the public, the sale of catalogues also being unprecedented, a third edition having to be printed. The lantern was skilfully manipulated by Mr. Banks and Dr. H. Scott Lauder, R.N.

#### FORTHCOMING EXHIBITIONS.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### WANTED A CHEAP ROLLABLE FILM.

To the EDITORS.

GENTLEMEN,—Their great and sudden success has shown that the new type of slow bromide papers has met a want which the photographic public had to look to other than our home manufacturers to imitate. Might I point out another great want, particularly of the amateur, in which it would appear that Continental makers will be first in the field, viz., a cheap rollable film. That it is used in the most expensive as well as the cheapest hand cameras, and the great variety of beautiful and convenient instruments of all kinds on the market to which it is adapted shows that in its universal applicability it is *facile princeps* as a means of carrying sensitive material.

But the amateur who is blessed with not too much worldly wealth recollects, as he surveys the tempting arrays of extra good value, pocket kodaks, cartridge kodaks, &c., that films costs three times as much as plates, and such luxuries cannot be for him. A stripping film on paper would (in the absence of something more convenient at the price) most nearly meet the needs of the case. The transference of the negative film to a glass basis ought to be done just as easily as the similar operation in carbon work, and form merely a detail in negative-making. In keeping qualities such a film ought to equal good bromide paper, which is practically equal to that of plates, and it would be proof against halation. Instead of costing three times as much as plates, it ought to cost considerably less.

If such films were put on the market, many would be able to convert their stand cameras into very efficient hand cameras at a small cost by means of the roll-holders, which can now be got very cheap.—I am, yours, &c., H.

#### PYRO AS A LANTERN-SLIDE DEVELOPER.

To the EDITORS.

GENTLEMEN,—Referring to Mr. Armstrong's letter in your JOURNAL of February 24, I can endorse all which he has said in favour of pyro for lantern slides, and add that the quicker developer is also greatly in favour of pyro as compared with hydroquinone, but I have been obliged with reluctance to give it up entirely owing to unevenness in development. I used ammonia, and I have found that sometimes, and very often, one

spot will develop quite densely before another portion commences to show much sign of starting at all.

I thought it might be due to improper mixing of the ammonia or unevenness of applying the solution, but no care in remedying these possible causes of the defects produced any better results. Then I thought that the film might be harder in some places than in others and to remedy this I tried soaking the plates in water and in plain pyro solution before applying the developer, but with no better result, and I was obliged to give up pyro altogether. The reading of Mr. Armstrong's letter revives the hope that I may be able to discover the cause of the trouble or to discover a plate on which I may work with success, for the pyro tones are just those which I like beyond all others. I have never tried soda as an accelerator with pyro.

I shall be much obliged if Mr. Armstrong can throw some light on these points.—I am, yours, &c.,

LOUIS MELDON.

31, Arisburry-road, Dublin, February 25.

### RETOUCHING WITH A PIN POINT.

To the Editors.

GENTLEMEN,—Apropos of Mr. T. M. Laws's note on the above, the enclosed little metal pencil may interest you. It is one of several made for me about ten years ago by Mr. A. Fenton, photographer, of Chester-le-Street. Mr. F. used them himself, and, I believe, sold them occasionally to those in want of an "easy retoucher."—I am, yours, &c.,

J. PIKE.

[We should think the fine-pointed metal pencil, which Mr. Pike kindly encloses, very useful for the purpose.—Eds.]

### THE FOCAL LENGTH OF A LENS.

To the Editors.

GENTLEMEN,—Mr. Dallmeyer's solution of the problem of measuring the focal length of a lens is perfectly satisfactory from a theoretical point of view, as, indeed, might be expected; but I have always found a practical difficulty in measuring the distance of the ground surface of a camera screen, when *in situ*, from any point outside the camera, and, of course, it is still more difficult to get the distance when both points are inside the camera. By making a variety of measurements and combining them, it can, of course, be done; but I did not think that procedure would suit those for whom I was writing, nor did I desire to trouble ordinary photographers with focal centres.

Allow me to suggest that opticians should adopt the practice laid down by the Paris Photographic Congress in 1887, and mark on the lens-mounting the place of one of the centres at least, adding the distance between them, as well as the focal length of the lens. When the centres are outside the limits of the mounting, its distance from a marked point might be given. Enlargers would thus have available all the information they require without any special investigations. It is true the enlargers are but a minority of the users of lenses, but the information could hurt no one.—I am, yours, &c.,

J. F. T.

### SACRED ART AND PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—The first four paragraphs of Ex Cathedra, your views and mine are thoroughly in accord. I know every one will not think the same, but I feel convinced your view of the subject is the right one, and so I speak.—I am, yours, &c.,

W. W. WINTER.

Midland road, Derby.

[A number of other letters, which the writers do not wish published, have also reached us, from which we have been pleased to find that our remarks have met with wide approval.—Eds.]

### CHEAP ENLARGEMENTS.

To the Editors.

GENTLEMEN,—Thinking it might interest you, I have sent you a circular emanating from the oldest established grocers in this city, and should be glad to have your opinion as to the best course to adopt to show them up, there are no less than ten or a dozen photographers in this city, and all classes are well catered for. I thought I should do one or two 12 × 10 bromide enlargements, and ticket them at 4s. 6d., and put the firm's circular one side of them and one of my own stating price, and with the intimation that I did not expect my customers to buy a pound of tea. Trusting I am not intruding too much on your valuable time, and any suggestion you can offer me will be very acceptable.—I am, yours, &c.,

ARTHUR A. NOAKES.

17, St. Peter's-street, Canterbury, February 21, 1899.

[The circular relates to the offer of 20 × 16 enlargements for 5s., and suitable frames for 4s. 6d., both of which can be very profitably produced at the prices. The best and indeed the only useful advice we can give our correspondents and others similarly situated is to

turn out work superior to these enlargements—to compete, in fact, both as regards quality and price. This is the surest way of making and retaining business. If the cheap enlargement schemes are the means of waking up photographers to the enormous possibilities of high-class portraiture, &c., they will ultimately prove blessings in disguise.—Eds.]

### COLOUR PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—The enclosed cutting was taken out of the "London letter" column of a local evening paper, and, as the writer of the paragraph states he had a specimen of the work, and pronounces it "a very creditable piece of photography, the colours coming out marvellously," perhaps the process has come under your notice, and you can enlighten us somewhat as to the merits of the work, or whether there really is anything in it or not. The "invention hailing from America," from which it differs "in many important respects," puzzles me a bit, as I think I have read in your JOURNAL that this is merely a repetition or modification of the three-colour processes. And what about the wonderful "Newquay" process of colour photography—the process above all processes which was to revolutionise the art of photography, and place in the hands of every photographer a simple and certain method of producing photographs in natural colours? "Cosmos," in his Jottings, rather shatters our long-cherished hopes when he speaks of "reserving his colour-photography reminiscences for his autobiography."—I am, yours, &c.,

Newport, Mon., February 21, 1899.

T. M.

[Appended is the paragraph our correspondent was kind enough to enclose. We have heard nothing of the "intelligent Russian peasant's" system of colour photography. On the latter subject the London correspondent of a provincial newspaper is, perhaps, the one authority least deserving of respect.—Eds.]

"CAZAR AND PHOTOGRAPHY.—The Czar is taking a paternal interest in other things besides disarmament. An intelligent Russian peasant has, I hear, invented a system of colour photography, and has been placed by the Czar in a position to perfect his appliances. I have had an opportunity of seeing one of the specimens of the man's work sent over to England for inspection. It is a very creditable piece of photography, the colours coming out marvellously. Details of the system have not transpired, but I am told that it differs in many important respects from the invention hailing from America."

### AN ALUMINIUM MICROSCOPE STAND, &c.

To the Editors.

GENTLEMEN,—In a recent issue of the JOURNAL I saw a notice of a microscope stand constructed of aluminium, excepting the working parts, which had been exhibited at the Quekett Microscope Club, and conveying the impression that it was an entire novelty. Since this instrument was antedated almost a quarter of a century, to my personal knowledge, it may not be uninteresting to your readers if a few particulars of this, perhaps the first microscope constructed of aluminium, be given in your columns.

In the spring of 1894 the late Mr. Joseph Beck, of the firm of R. & J. Beck, making one of his visits to this country, brought with him one of their "Large Best Binocular Microscopes," with a full outfit of accessories, and a set of objectives from a four-inch to a one-fortieth of an inch, every portion of which, excepting the working parts, was constructed of aluminium. All of this apparatus, stand, accessories, and objectives, was "packed portably" in a single case of mahogany, so light that it could be carried by one hand, readily, as an ordinary portmanteau. In the autumn of the same year I took this outfit to San Francisco, where it was left with a member of the Microscopical Society of that city for the consideration of 1800 golden dollars, duty paid.

I also noticed in your issue of January 13, some commendatory remarks as to the Velox printing paper, which I can most heartily endorse. For the perfect rendition of the delicate details of a photo micrograph I have never seen any printing medium (with the exception of glass) at all equal to it, whilst the ease of manipulation must recommend it to every user. And here, perhaps, I may give a hint to fellow-workers that will prove useful. The most perfect finish to be obtained with this, as well as with all other enamelled or glossy-surface papers, is had by squeegeeing them upon an ordinary ferrotype plate, from which they should peel off when dry, smooth, glossy, and perfect; but, alas! how frequently doth a print "stick faster than another," refusing to leave the plate, ruining not only itself but the placid temper of the operator as well. Being greatly troubled in this direction at times, I set about discovering a remedy, and found it. If the prints, after being duly fixed and washed, be transferred to a bath of one drachm of formaldehyde to eight ounces of water, for a few minutes, they may be squeegeed on a clean ferrotype plate with the absolute certainty of coming off when dry. Having treated several thousand prints in this simple manner without a single failure, I am enabled to speak positively as to its success. But the plate must be clean.—I am, yours, &c.,

W. H. WALMSLEY.

4248, Pine street, Philadelphia.

## THE R.P.S. AND PROFESSIONAL PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—I think we owe a debt of gratitude to THE BRITISH JOURNAL OF PHOTOGRAPHY for the publication of a letter signed "Pro bono Publico."

If the anonymous conceived the letter for "the good of the public," your valuable paper contained it "for the good of professional photographers."

I do not dare to discuss the first part of the letter in question, as I am in no position to judge the actions of the Royal Photographic Society, and therefore my belief in this high institution cannot be shaken, but it is the second part, dealing with the "make-belief amateur," which deserves to be printed in red letters, and be quoted in all the photographic journals of Great Britain and the Continent as a most useful contribution to a Correspondence column. Appeals, like "Pro bono Publico's," should be received with enthusiasm, lead to an open discussion of the subject, and to a consequent amalgamation of men who have learnt and do understand this branch of work in such an enormous field as photography.

There are a few Continental societies trying to protect the photographer's assistant from cheap competition, but there are none to protect the real professional photographer from the amateur who opens a photographic studio without knowing how to develop a plate properly. No wonder advertisements appear in photographic journals, asking for "attractive show-case specimens" cheap!

You do not agree with "P. B. P." in his criticism of the Royal Photographic Society. Well, this question will have its pro and con, but I take it as granted that you published the letter on account of the second question raised, which deserves public attention.

The second question, pronounced as a subject of manifest importance, which will advance the material interests of the profession. I think it will do more; it will raise the artistic quality of photographic trade productions and restore the good name of the profession in the eyes of the general public, which had reason to regret that we allowed our profession being dishonoured by individuals "Pro bono Publico" letter deals with.

As efforts in the indicated direction will not meet with general acclamation, why not fight with "open vigour" in a struggle to regain what's temporarily lost?

Names of some prominent photographers attached to their contributions would give confidence and courage to their minor brethren, who are, perhaps, too modest to raise their own voice in such important a dispute. A leader will easily be found amongst them, and then let us act *viribus unitis*.—I am, yours, &c.,

HENRY O. KLEIN.

Surbiton.

## THE LEEDS CAMERA CLUB AND THE YORKSHIRE PHOTOGRAPHIC UNION.

To the Editors.

GENTLEMEN,—Mr. Ezra Clough, seeking, like Alexander, for new worlds to conquer, and with his appetite whetted by the wholesale slaughter of Editors, Frank Sutcliffe, and suchlike big game during the last few months, has condescended to stoop down to such insignificant sport as a correspondence with me. Of course, in the natural order of things, the supply of lions could not be equal to our gallant Tartarin's demands, but I scarcely anticipated so early an attention, and I am correspondingly flattered by the distinction.

I and my Society, the Leeds Camera Club, have ventured to differ from Mr. Clough on the question of the advisability of our joining the Yorkshire Union of Photographic Societies, and the result is a round of blank across our bows.

In reply, personally I again repeat that federation has failed in Yorkshire, and I particularise, as an instance, when it was attempted by the Affiliation Committee of the Royal Photographic Society, and when a local sub-Committee, with a local Secretary who was a fellow Clubman and personal friend of Mr. Clough, was appointed some years ago, and has since not been heard of. I also say, in confirmation of what I have previously said, that societies are conflicting atoms, just as Mr. Clough is, and that personally I should be very sorry if any of my own Club was not, inasmuch as quiescence means standing still, and standing still means retrogression; that the proposed Union is itself an instance, inasmuch as it is founded, to a great extent, on feeling, and openly enters into rivalry with the Affiliation scheme. I say that the inception of the new Union was a mistake, by Mr. Clough's eight geniuses, who were all Bradford men, and who, with the help of other Bradford men, proposed, seconded, and appointed the Chairman (another Bradford man) and the Secretary (another Bradford man), and the subsequent hole-and-corner-proposed appointment, too, of myself as Treasurer by this self-ordained covenant, had a little too much of the same flavour to be satisfactory or to inspire confidence. Though Mr. Clough will perhaps not realise it, too much Bradford is apt to pall, and it palled first time on us. As to the practicability of a scheme wherein you are to have two sets of lectures, paid and unpaid; where every society is to have two

lectures free, and an equal number in addition for every lecture given by it to the Union; in other words, where the miracle of pouring a quart out of a pint jug is to be attempted; where, with twelve societies, and a subscription by them of certainly under 10L., it is proposed to pay a secretary, and run the show, time will prove. As it is, we propose to run "on our own," and I know of no section in the statute-book to prevent us.

I should be failing in that courtesy which is essentially characteristic of Mr. Clough if I did not thank him for the warning he gave me some time ago of the proposed "go for me," and, if he thinks that the game, be it either the Yorkshire Union game or the Ezra Clough game, should be necessarily played in this manner, let me assure him I have no objections. Your feelings towards Mr. Clough are of the most sympathetic description. I realise that, like the colt in the spring-time, he, overcome by his feelings and surroundings, is kicking and galloping over the greensward. I should suggest he should kick his heels now for all his worth, for very soon he'll be harnessed to the Yorkshire Union, and then there'll be an end to any colt's tricks.

Thanking you in anticipation for the demand I have made on your valuable space,—I am, yours, &c.,

W. J. WARREN.

Bedford street, Leeds, February 26, 1897.

## AN ASSISTANT'S DILEMMA.

To the Editors.

GENTLEMEN,—On perusing the pages of your JOURNAL, which I take every week, I came across a paragraph—"An Assistant's Dilemma," and, as my case is very much the same, I cannot help but replying.

About six weeks ago I sent you some of my work upon which to express an opinion and your reply was, "Although it was not the highest-class work yet it was very good class indeed." Now, since then I have answered three or four advertisements in your paper every week, but without success, and I cannot understand it at all. I do not ask a large salary, in fact perhaps too low. I am not only a good retoucher, but good operator and also miniature painter, and yet cannot obtain an engagement so "W" need not be disheartened. The only reason I can give for it is that either this country is overcrowded with good photographers or some of the advertisers are humbugs. I am afraid there are too many in the same fix. I should very much like to see a reply from one or two other assistants as to their opinion on the subject. Trusting you will be able to find space for this, and thanking you for same,—I am, yours, &c.,

F. S.

## NORMANDY.

To the Editors.

GENTLEMEN,—I am thinking of spending a few weeks in Normandy, going by the Newhaven route to Dieppe. I should be pleased if, through THE BRITISH JOURNAL OF PHOTOGRAPHY, some of its readers would kindly give me a little information respecting the places to visit on the coast, accommodations, &c. I am taking with me my hand camera, and would like to find out those old-world places and fishing villages with those quaint, picturesque fishing folk; also any information respecting permits to use my camera, and so forth, hotels and their charges.—I am, yours, &c.,

RAMBLER.

[Will some reader who has been fortunate enough to have the opportunity of photographing in Normandy oblige our correspondent with the information asked for?—EDS.]

## "ROUGH ON THE CRIMINAL."

To the Editors.

GENTLEMEN,—Does not the following paragraph from Monday's *Daily Telegraph* strike you as very hard on the criminal?

## CINEMATOGRAPHING A MURDER.

St. Louis (Missouri), Sunday.

During the trial yesterday of a man named Campbell Allgair for murder the prosecution introduced a set of cinematograph pictures giving the entire scenes of the crime. The instrument, which was kept in the room where the murder was committed, happened to be working at the time, and recorded the details of the killing. The lawyers for the defence say that if their client is convicted they will appeal against the use of the photographs as not being, in this instance, among the evidence legally allowable.—*Dakrid*.

I can't say I have much sympathy with murderers, but I do hope the love of fair play so dear to Englishmen will always induce them, when they have a cinematographic apparatus that happens to be working, to put up a notice—

## BEWARE OF THE CINEMATOGRAPH.

Dion Boucicault's absurdity in his play of the *Octoroon* isn't "in it" now.—Next, please!—I am, yours, &c.,

FAIR PLAY.

## AN OFFER OF ASSISTANCE.

To the Editors.

GENTLEMEN,—Should you at any time be applied to for information respecting India (or the East in general) by your subscribers—professional or amateur—I should be happy to be of service, having just returned from that hemisphere, having terminated an engagement lasting three years. By so doing I trust I can further, in some slight degree, the resources of THE BRITISH JOURNAL OF PHOTOGRAPHY, which publication I have found invaluable, and the which is to be discovered in the remotest corners of civilisation.—I am, yours, &c.,

ARTHUR CECIL COLE.

224, Earl's Court road, Kensington, February 26.

## Answers to Correspondents.

\*.\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\*.\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*.\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

## PHOTOGRAPHS AND DRAWING REGISTERED:—

E. C. MacMahon, 23, Academy-street, Inverness.—Drawing of railway show-card.

A. J. Ashbolt, 29, High-street, Southampton.—Photograph of the Southampton Foot ball Club cup-tie team, 1898-9.

Jesse Landon, 134, Queen's-road, Watford, Herts.—Two photographs of two young rats in one trap; back and front views.

H. A. Chapman, 235, High-street, Swansea.—Two photographs of underground chapel used for divine service in Mynydd Newydd Colliery, near Swansea.

F. H. CARTER.—Many thanks for your letter.

G. S. C. (BURY ST. EMUNDS).—The address of the agent for the lenses is Mr. H. F. Purser, 33, Hatton Garden, E.C.

ONE IN DOUBT.—Peruse the Copyright Act in the ALMANAC for 1899. To make assurance doubly sure, the register should be consulted.

T. M.—So far as we know, no patent is in force for the device described, which we have seen applied to many cameras other than those of the makers named.

E. H. MICKLEWOOD.—See a reference to the subject elsewhere in this number. The films are not yet obtainable in Great Britain; they will probably reach here shortly.

"REGISTERED."—S. H. HART says: "Will you inform me whether it is necessary to have the word 'registered' printed on the mount when a photograph has been registered?"—In reply: No, not necessary.

COMBINED BATH.—A. S. B. says: "Would you kindly give me a reliable formula for combined toning and fixing for gelatine prints—preferably one without alum or lead, and if possible a neutral bath."—It is a very vexed question, and always has been whether any combined toning and fixing bath is reliable. The best are those given in the ALMANAC. The old combined toning and fixing bath, universally used in the early days of photography, and which yielded prints many of which are now as good as when first done, was hyposulphite of soda, 12 ounces; water, 1 pint; chloride of gold, 15 grains. That was for albumen or plain salted paper and contained neither alum nor lead. But we doubt if the present gelatine papers will stand such a bath.

COPYRIGHT.—GWALIA says: "Would you be so kind as to answer these questions? 1. I photographed a rocket brigade recently. I have sold thirty copies of whole-plate for 2s. each. I gave them a 12×10 bromide enlargement, worked in black and white, gratis; they are going to present it to the late first officer, who resigned recently. Can I copyright same, and which way shall I proceed to do so? 2. I wish to join the Copyright Society; what course shall I take to become a member?"—1. You can register (copyright) the photograph if you were not paid for taking it. Send our publishers three prints and 1s. 7d., and they will effect registration for you. 2. Address Mr. Henry Gower, Photographic Copyright Union, London Chamber of Commerce, Botolph House, Eastcheap, E.C.

OWNERSHIP OF STUDIO.—A COUNTRY PHOTOGRAPHER says: "In your Answers column a correspondent, Edmond Wallis, asks about the ownership of studio. I have always understood that anything put up for business purposes could be removed; that has been my experience. I have built three studios. The first the landlord bought to turn it into a greenhouse when I left. The second I had pulled down myself, although I am not aware, or rather I forget, if anything was said about it in the lease, and I shall have no hesitation in pulling down the third if I want to."—In reply: As we said, the law is a little knotty on the point. We thank our correspondent, but neither of his cases was contested in a law court. What are and what are not tenants' fixtures is often a very vexed question.

SPOTS ON PRINTS.—VERAX says: "Will you kindly give me your opinion as to the cause of these spots appearing on a lot of my prints? Process: albumenised paper, sensitised by Blackfriars Company; acetate of soda toning bath. Mountant: starch."—This is one of the unanswerable questions dealt with in our issue for February 10, to which we would refer our correspondent. The spots are clearly due to the manipulations, and several laches in them would produce similar spots. The paper, toning bath, or the mountant have nothing to do with the trouble.

COPYRIGHT.—B. H. There is no question about the copyright and its registration, if the facts be as stated. We should recommend you at once to take proceedings for damages and an injunction to restrain further issue of the publication. There is very little doubt that, when proceedings are commenced, the publishers will drop their "bluff" and be very anxious to come to terms with you. If the case goes into Court, which they will not be foolish enough to allow, you will secure substantial damages. But lose no time in applying for an injunction to restrain further publication.

GELATINE; CHONDRIN; BROWN MARKS ON PRINTS.—A. BAKER says: "I see by your JOURNAL of September 23, 1898, you believe there is one firm that makes photo emulsion gelatine in England. Will you kindly give me the address? I think my failures are due to bad gelatine. 2. Will chondrin form in a white lump when a concentrated solution of chrome alum is added? 3. Can you tell me the cause of the brown marks on the enclosed prints?"—1. We do not now know of any firm that supplies gelatine emulsion. 2. Chondrin is precipitated by alum. 3. Carelessness; allowing the prints to stick together in the fixing bath.

INTENSIFICATION.—G. B. says: "I have tried the intensifier as recommended by Mr. Bolton in your JOURNAL a fortnight ago. I added two or three successive ten drops of intensifier to the pyro-ammonia developer, and left the plates in bath ten or fifteen minutes altogether. Result: 1. No appreciable intensification. Why? 2. The plates were covered with patches of metallic silver. Why was this? 3. Would a weak solution of iodine, followed by cyanide, remove hypo from a plate? 4. And is a trace of cyanide injurious to the ferrous-oxalate intensifier?"—1. We cannot say the reason of the failure. 2. This was, in all probability, due to the vessels not being thoroughly clean, and a similar cause may account for failure No. 1. 3. If by "hypo" is meant hyposulphite of soda, water alone will remove it. 4. Yes.

FOCAL LENGTH OF LENS; SHUTTER.—THOMAS ROGERS says: "1. I have just bought a hand camera, Fallowfield's Facile, which has a view lens and one fixed stop three-eighths of an inch in diameter, and am anxious to know the true working aperture of this lens. The distance from the plate to the inside face of lens is exactly four and five-eighths inches, and one inch from this comes the diaphragm. To obtain the focal length of this lens, from what point must I measure? 2. Enclosed please find drawing of the shutter which works in front of the diaphragm. Can you tell me whether the efficiency of this shutter is as high as a roller-blind shutter, such as a Thornton-Pickard? If not, perhaps you may be able to suggest some means of fitting such a shutter in place of the one at present fitted, as the space between the stop and inside front of camera body is less than one-eighth of an inch? The drawing is the exact size of the original. You may know enough of this particular camera to be able to recommend it, or to give your opinion as to whether it can be used as a practical camera. This last four years I have only used half-plate stand camera, and should like to go in for hand-camera work as well, but am afraid, with this lens and shutter, I shall get many under-exposed negatives, using Castle plates."—1. According to these measurements, the aperture of the lens is, roughly,  $f/13$ . 2. It is very good for a cheap form of shutter. Doubtless the makers of the camera could fit the other shutter you mention to the camera. The camera is one with which excellent pictures can be taken, and it can be fitted with a lens of the rapid-rectilinear type, which will, of course, work much quicker than the single one with which it is now furnished.

DETENTION OF NEGATIVES.—L. L. says: "May I trespass on your time and kindness to give me an answer to the following statement of facts? In October, 1895, I was in business as photographer in Newport, Mon. In that month a traveller from — received from me two negatives for enlarging, and in a day or so received from the firm an acknowledgment of my order. But I never received either negatives back or enlargement ordered, and after writing them once or twice I let the matter rest. Since then I have sold my business and come to Manchester in the employ of a firm of photographers. The other morning I opened a parcel containing a specimen enlargement sent to my firm by —, and there was a nicely coloured enlargement (12×10) of my daughter, the negative of which was one of the two I had sent to the first-mentioned firm more than three years before. Now, it seems to me there is a nice little bit of roguery here. I have not the slightest doubt but that other photographers have suffered in the same way. Naturally, I should like to make these people pay. I have an idea the two firms are one and the same. Have I any case? Should I proceed against the first for detention of negatives, or against the second for publication of work that is mine? And I suppose a solicitor would be the best to undertake the case? Or don't you think it is worth the trouble? There is an undoubted fraud somewhere, and, as an Englishman, I don't like being done. I can, of course, give you fuller details of the matter, if you care to have them, as you may, being of interest to the profession generally."—We certainly endorse the opinion expressed by our correspondent. It seems to us that the only remedy is to sue those to whom the negative was originally intrusted, whether they be the present Company or not, if he can find out who they are. Unless our correspondent can find out something about the people beforehand, it might be a waste of money to put the matter in the hands of a solicitor, who will, of course, have to be paid.

## EX CATHEDRA.

It has been estimated that the gelatino-chloride process supplies seventy-five or eighty per cent. of the sensitive printing paper used by photographers. Next to dry plates, it is probably the largest item of photographic manufacture and trade. No great amount of imagination, therefore, is needed to realise that an increase in the price of gelatino-chloride paper would be a very serious thing indeed for those who make it and those who use it. We gather that such an advance is well within the bounds of probability in Great Britain; it has already taken place in the United States, and, we believe, on the Continent. In America, according to our exchanges, the matter has given rise to considerable ferment, and no wonder.

\* \* \*

THE effect of an advance in price of British-made gelatino-chloride paper would mean the dislocation or the disturbance of a very important branch of manufacture. If the photographer is called upon to pay 1s. 3d. for what he has hitherto been in the habit of paying 1s.—to state the case in the form in which it is most likely to occur—his preference for gelatino-

chloride printing might be somewhat difficult to sustain. It can easily be supposed that he would not only revolt at the increased price, but would be induced, without difficulty, to transfer his allegiance to a printing process which would supply a substitute for gelatine at perhaps half or two-thirds its cost—albumen, for example, which would then stand a great chance of being more than temporarily resuscitated. Thus, the object of those upon whom the responsibility of raising the prices of gelatino-chloride would rest might not, in the end, be achieved; gelatine would be replaced by albumen, the manufacture of the former would be decreased, and albumen paper would again be worth the attention of English sensitisers working on a very large scale. If this inevitable result of a rise in price of gelatino-chloride paper has not been foreseen by those who are alleged to be contemplating action in the matter, they may acknowledge that, in calling their attention to it, we have taken a course not altogether inimical to their interests. In the long run we are convinced that neither photographers nor the public would be the sufferers by a rise in price of gelatino-chloride.

\* \* \*

WE are informed that ill health obliges Mr. George H. James shortly to leave England for a time. Mr. James is known and esteemed by a wide circle of friends. An old member and past President of the West Surrey Photographic Society, he has worked hard for years in his own immediate neighbourhood to promote the interests of photography, of the pictorial side of which he was always a cultivated and prominent exponent. As an experimentalist in carbon printing, he was led, last year, to work out the adaptation of the gum-bichromate process to commercial requirements, and with considerable success. It is to be hoped that Mr. James will not long be absent from England, as good workers of his stamp are none too plentiful in photography. On Wednesday evening last the members of the West Surrey and numerous friends gave a farewell entertainment to Mr. James, who was the object of many manifestations of goodwill and hearty wishes for a speedy return to health.

\* \* \*

MESSRS. CATHERALL & PRITCHARD, Ltd., photographic publishers, of 326, Camden-road, N., and Chester, write: "On several occasions of late you have drawn attention, in the pages of THE BRITISH JOURNAL OF PHOTOGRAPHY, to the revival of

stereoscopic slides, and have instanced the efforts of one or two firms to provide them at an extremely low rate. These productions are usually in colotype, or some similar mechanical process, and, when taken in bulk, are often very uneven in quality, as the low price precludes any rejection of inferior prints. Some months ago we decided to again take up the production of stereoscopic slides, and to issue a really good slide at a price but little in advance of the colotype slide. You have always shown such interest in stereoscopic work, that we have much pleasure in submitting to your notice some slides we are now issuing to the trade in silver, and which have as careful work put into them as at any time in our history."

\* \* \*

THE series of slides Messrs. Catherall & Pritchard have been good enough to send us illustrate Welsh and Devonshire scenery, and the subjects lend themselves admirably to binocular treatment, the views having been chosen with an eye to securing natural effects of relief and solidity. The prints are on albumen paper, and better images for the purpose could not be desired, every detail in the shadows being shown and the high lights stopping short of hardness. We are always glad to have evidence of an increasing interest in stereoscopic photography, and help promote its popularity; and such beautiful slides as those which Messrs. Catherall & Pritchard are issuing should materially aid us in our efforts on behalf of this fascinating branch of work.

\* \* \*

IT may be remembered that, on February 21, a meeting convened by the National Photographic Record Association was held for the purpose of discussing the means to be adopted for securing photographic records of old and disappearing London. The tangible result of that meeting was the formation of a committee whose duty it should be to arrange details of procedure. We here give the names of that body as it is at present constituted, but it is probable that some additions will be made to it:—Rev. J. O. Bevan, F.S.A.; Messrs. F. Goddard, South London Photographic Society; W. R. Stretton, Photographic Club; J. T. Price, West Surrey Photographic Society; E. Eastwood, Lewisham Camera Club; H. B. Wheatley, Society of Arts; J. W. Thomas; C. R. Ashbee; Col. J. Waterhouse, R.P.S.; W. Oxley; Philip Norman, F.S.A.; Dr. Mill, F.R.G.S.; R. Nevill, F.S.A.; Basil Lawrence, Camera Club.

\* \* \*

THE Pennsylvania Academy of the Fine Arts announce that, under joint management with the Photographic Society of Philadelphia, the Philadelphia Photographic Salon for 1899 (second year) will be held in the galleries of the Academy, from October 22 to November 19, 1899. The success of the first Salon has conclusively demonstrated the existence of a field for an American Exhibition devoted exclusively to pictorial photography in its highest sense. The aim of the Salon is to show only such pictures produced by photography as may give distinct evidence of individual artistic feeling and execution, rigidly selected by a jury composed of well-known artists and artistic photographers, whose certificate of acceptance shall be the only award. All those interested in the purpose of the Salon are invited to give it their cordial support and encouragement, both by submitting specimens of their best recent work and by making it favourably known to others. This preliminary notice will be followed in due course by a full circular, with all details, entry forms, &c.

IT is announced in *Nature* that, in order to afford the members of the Franklin Institute, Philadelphia, the opportunity of cultivating an interest in photography and microscopy, with especial reference to the branches of photographic optics and mechanics, photo-micrography, photo-chemistry, and their manifold applications to the various branches of the arts and manufactures, a photographic and microscopic branch of the Chemical Section is being organized. Of interest in connexion with this movement is the fact that the Chemical Section of the Institute has lately become the residuary legatee of the large and valuable accumulation of scientific books and physical and chemical apparatus of the late Mr. Matthew Carey Lea, who, in his day, as our readers know, was one of the foremost experimentalists in photographic chemistry.

\* \* \*

OUR contemporary also states that at the meeting of the Franklin Institute, Philadelphia, on February 15, Mr. L. E. Levy exhibited and described the acid-blast process invented by him to facilitate the etching of photo-chemical engravings. The invention consists essentially in the application of a spray of finely atomised etching liquid instead of the immersion bath at present in use, the spray being driven against the plate by a powerful blast of air from an air-compressor. Under the impulse of the blast the etching proceeds very rapidly. The heat evolved by the rapid chemical decomposition of the metal is absorbed by the expansion of the compressed air as it escapes into the etching compartment, and this results in keeping down the temperature of the plate and the etching liquid to a normal degree. As each succeeding globule of acid impinges on the metal in the direction in which the etching is required to proceed, the process can be continued to a depth beyond which the finer and closer lines of the design would become too frail to bear the strain of printing, and at that point the etching is stopped and the finer lines are protected by powdering in the usual way, after which the etching can be carried to the requisite depth. Attached to the etching box is a washing compartment, into which the plate-carrier is slid when the etching liquid is to be washed away from the plate.

\* \* \*

WE understand that an Exhibition of acetylene gas and the methods of producing it will be held at Budapest during May 14–28. The Exhibition is divided into two groups—the "manufacture of carbide of calcium" and "acetylene lighting," which are subdivided so as to include everything at present devised in connexion with acetylene gas. Particulars can be obtained from the President, M. Maurice Gelléri, Budapest, VI. Uj-utca 4.

\* \* \*

A PARIS correspondent says that by slow degrees the photographs of M. Loubet are replacing those of M. Félix Faure in the shop windows and the kiosks. The counterfeit presentments of the late President, however, will preponderate for some time, as it is evident that the shopkeepers want to sell off the large quantities of them which they have on hand. Half-size photographs of M. Loubet, wearing the broad sash of the Legion of Honour, have in the mean time been sent to all the Ministers and their principal secretaries. Engravings of the same portrait are to be forwarded in a few days' time to all high public officials and to the Prefects of Departments.

## THE DETENTION AND MISUSE OF NEGATIVES.

LAST week we, in the Answers column, replied to a correspondent; his complaint was this: A few years ago he intrusted to a traveller for a "firm"—now, we think, defunct—two negatives for enlargement, one of them being of his own daughter. In due course he received an acknowledgment of the order, but he was unable to get the enlargements or the negatives back. The other day, at another place, he opened a parcel containing a specimen enlargement sent by another "firm" and to his astonishment found it contained a coloured enlargement of his daughter's portrait from one of the two negatives sent to the other firm three years before, the names of the two firms being given. Now, it is very clear that he could sue the "firm" to whom the negative was intrusted for its illegal detention, and also damages, if it is in existence or he knew who the "firm" was, or is, and would get redress if the concern were worth "powder and shot." With regard to the second firm that now have the negative, and are trading upon it, he could, no doubt, obtain an injunction to restrain its further use, but that would entail considerable law costs, which some one would have to pay, the losing party if they have the means.

This subject opens up a question of some interest. The negative of a sitter is the unquestionable property of the photographer, but he cannot use it for any purpose of his own against the will of the sitter. He sells his business, and with it the negatives, and, presumably, his successor will follow the same course in his own interests. But assume that the photographer who took the negative becomes bankrupt, and his effects, including the negatives, are sold at auction, and are purchased by different people, what then? Are the purchasers restricted from putting them to any use they may think proper? This question occurred to us some time back when, on walking through the Friday market in the Caledonian-road, we saw packets of negatives of the nobility we recognised as being taken by a West-end house that had "come to grief." The names of the sitters were upon them, and they would have made excellent specimens for show-cases, and possibly have been utilised as such. Is there any law to prevent that, seeing that the negatives were sold in "market overt?"

A new Bill relating to copyright is just now being promoted by artists, and the Royal Photographic Society has appointed a committee to watch over the interests of photographers in the matter, and this point should receive some amount of consideration. It may be well to get a clause inserted in that portion of the Bill relating to photography, to the effect that it is illegal to use the negative of any sitter taken in the ordinary course of business, by any one into whose hands it may eventually fall, without the sanction of the sitter. This would be in the interests of photography, by inspiring confidence in sitters. In the case cited of the market, it would not be pleasant to the Countess of Sand-So, the Lady That, or the Honourable Miss Dash, to know that their portraits might figure as specimens in third or fourth-rate show-cases, or perhaps as "beauties" on match-boxes or in packets of cigarettes.

## VANISHING LONDON.

The efforts of Sir Benjamin Stone will, no doubt, be appreciated in securing a photographic record of rapidly disappearing buildings of historical interest—and none too soon—and every one will wish the idea the success it deserves. There are

many, however, who may desire to secure pictures of such objects for their own private collections. It is announced that the south side of that picturesque old London street, Holywell-strand, Strand, is expected by the London County Council to be cleared away before the end of the year. But, doubtless, long before that time, some of the shops will be closed and boarded up, or partially hidden by scaffolding. Therefore no time should be lost in securing what may be desired—i.e., views showing the street in its original condition. We would suggest with this street, as with several of a similar character, that the pictures be taken stereoscopically. This old street, with its continuous crowd of pedestrians and occasional stray vehicle or hand cart, makes excellent subjects—and there are several—for the stereoscope.

There is another phase of vanishing London that it will be interesting to secure photographic mementoes of while the opportunity lasts, namely, the congested street traffic in many of the London thoroughfares. There is now no question that, shortly, a great deal of that will be a thing of the past. Already the Strand, since the police have interdicted the "crawlers" from this thoroughfare, presents quite a different appearance from what it did a month or so back; and, when more traffic is diverted, the altered appearance of the Strand and other streets will be still greater, and the record of what they once were lost. Here, again, stereoscopic pictures will be the more interesting, and they may be easily secured with a stereoscopic hand camera. If they were, they would, by comparison with those taken by the late Mr. Wm. England, Blanchard, and others in the "sixties," show the difference between the London street traffic of 1899 and the period alluded to.

While on this subject, we may as well allude to another interesting spot, though not the London Strand, that is threatened, namely, Strand-on-the-Green. Kew Bridge, which, though not handsome in itself, yet makes an excellent distant background for views, looking up the river, of Strand-on-the-Green, is very shortly to be removed. It would have been done ere this but for some little hitch between the Surrey and the Middlesex County Councils. That is all arranged now, and the work is to be commenced at once. It was just mentioned that Strand-on-the-Green was also threatened. The local press is now calling attention to this neglected district and the unhealthy state of some of the dwellings there. If some of these old cottages are removed—and these, doubtless, will be—and modern dwellings erected in their place, Strand-on-the-Green will be lost to artists and photographers, to the former of which it has always been a happy hunting-ground, for, on a fine summer day, one rarely passes without seeing half a dozen or more at work, sketching or painting. At this spot a dozen or more excellent stereoscopic pictures—for it is admirably suited to stereoscopic work—may be obtained within a quarter of a mile; indeed, it is doubtful if so many good subjects for the camera are to be found in so small a space within half a dozen miles of the Marble Arch.

**Albumen versus Gelatine.**—The article by Mr. Edward Dunmore, in our last issue, should be read and duly considered by every photographer. Mr. Dunmore is an old hand and knows what he is writing about. He points out the weak and the strong points, dispassionately, of both the albumen and the gelatine printing processes, more particularly the probable permanence of the results. Mr. Dunmore dwells on the effects of carelessness in the working of both methods, and particularly points out the evil of long washing, or soaking, of albumen prints. As we have been saying for many

years past, the quicker albumen prints are washed, that is, thoroughly washed, the better it is both for the appearance and the stability of the results. Albumen may not, at present, be so largely used by modern photographers, particularly amateurs, as gelatine, but it is not yet dead, and we surmise that it will take a lot of killing before it becomes so.

**One-solution Sensitiser for Paper.**—Niewenglowski points out that the use of a single solution for sensitising paper was suggested by Liesegang in 1872, and that the following will give good results, provided a fairly heavily sized paper is taken and the sensitised sheets are used within twenty-four hours:—

Silver nitrate .....	3 parts.
Uranium nitrate .....	30 "
Distilled water .....	10 "
Absolute alcohol to .....	100 "

This solution must be kept in the dark or in a brown bottle, and the paper must be coated with the solution by gas or artificial light, and dried in the dark. A blue-black tone may be obtained by immersing in a solution of ferric chloride, to which a few drops of a solution of ammonium sulphocyanide have been added. It is advisable to wash the print in water acidulated with nitric acid at first and then in plain water.

**Ammonium Persulphate.**—Herr Schöncchen, writing in the *Photographisches Centralblatt*, states that this salt is made by the electrolysis of a solution of ammonium sulphate, and that Lumière and Seyewitz explain its reducing action on the silver image by the formation of a double sulphate of ammonia and silver according to the equation—

This explanation is, however, insufficient to account for several things that have been noticed, especially that fresh-made solutions will not act as reducers. From a series of experiments, Schöncchen states that an aqueous solution of the persulphate is gradually decomposed into ammonium sulphate, sulphuric acid, and oxygen, this being in the state of ozone—

Oxygen cannot act upon silver, but ozone will, and converts it into oxide or peroxide, which, *in statu nascendi*, would combine with the sulphuric acid and form silver sulphate.

**White Silver.**—The well-known French chemist, M. Mercier, states that, if a plate, normally exposed, be immersed in the following solution for one or two hours, a negative image is obtained which is white, but is so feeble as to be but of little use practically.

Sulphate or salicylate of eserine .....	1 part.
Metabisulphite of soda .....	2 parts.
Anhydrous sulphite .....	3 "
Carbonate .....	5 "
Water .....	100 "

Eserine, or, as it is sometimes called, calabarine or physostigmine, is the active principle of the Calabar bean (*Physostigma venenosum*).

**An Explanation Wanted.**—At the December meeting of the Namur section of the Association Belge de Photographie, M. Rousseau complained of the accidents which had befallen his prints which he had sent to the last Exhibition of the Royal Photographic Society. M. Rousseau stated (1) that one print had been pierced right through with a nail; (2) that three of his enlargements had been unmounted, spoilt, soiled, cut, and scratched, the frames destroyed and peeled off, and put together again in certain places; (3) the glasses were broken, and that there were no bits of glass in the packing, showing that this had been done before packing; (4) a frame so broken that it would not be possible to use it again; (5) and, lastly, a print had been taken from its frame; nothing better was found than to break the glass, and, as the print was pasted to its cut-out mount, it had been detached without any care, and it had

been rendered absolutely useless. These complaints were formally entered on the minutes and ordered to be published in the *Bulletin Belge* as an advertisement of the courteous method in which the Royal Photographic Society treated the prints sent to its Exhibition. M. Rousseau, we note from the catalogue, had no picture accepted.

**Rembrandt.**—There is at the present time to be seen a very fine collection of paintings by Rembrandt at Burlington House. They, with others, were shown last year in the Rembrandt Exhibition at Amsterdam. Amongst them are some lent by the Queen, the Duke of Westminster, the Duke of Devonshire, and others from their private collections. There is also on view—opened last week—in the gallery attached to the Print Room of the British Museum, a fine and large collection of drawings and etchings of Rembrandt's, also by some of his pupils and associates, as well as by members of his craft next to him in importance. Rembrandt's work, especially should be studied by photographers for its bold treatment of lights and shades, and the present opportunity, which may not occur again, should be embraced. Speaking of painting, it is announced that the Queen has promised to lend some of the best of her Vandyks for the Vandyk Celebrations at Antwerp in the early autumn. It may not be generally known that Her Majesty has, in her private collections at Windsor and Buckingham Palace, some of the finest Vandyks in this country.

#### VELOX FOR PROFESSIONAL WORK.

Few of us old professionals, a couple of decades back, could have imagined the conveniences we at present possess. Now almost everything is supplied ready for use, accompanied by full directions for its employment; indeed, there seems little left to learn in photography. How often have we sighed in the old days, during dark and foggy weather, for a paper with which good and uniform prints could be quickly obtained! Bromide paper we have had with us for some time, and, to an extent, it fulfilled that end. But, when the work had to be intrusted to some printers, who could ensure even a dozen prints all of equal depth and colour? or, if they were obtained, what was the proportion of paper wasted in obtaining them?

Now we have a new power at command in "Velox," which not only gets us over the trouble just referred to, while at the same time it yields just as pleasing results, so far as colour is concerned, as the old bromide papers. With the usual method of working, this paper yields a fine rich black, very similar to a platinotype. But, with a modification in working, which I shall presently refer to, any colour, from a bright Bartolozzi red, through sepias, to rich warm-brown blacks, can be obtained by development alone, without any after-toning, which closely resemble carbon pictures. Such is Velox paper, for which the old firm of J. J. Griffin & Sons are the agents. I cannot, of course, pretend to give details of its manufacture or the composition of the emulsion with which it is coated, though I fancy, from its behaviour and the rich colour it yields, I shall not be far wrong in saying that it contains a chloride as well as a bromide. It is of two kinds—"Velox" and "Special Velox"—with three grades of each. The first is best adapted for weak and flat negatives, as it tends to give strong contrasts. The latter gives softer effects with vigorous negatives such as are generally produced by professionals, therefore it is that which I recommend them to employ. It is more sensitive than the other, yet not sufficiently so to entail any greater precautions against light and its working.

Having had some experience of late with the paper, a few practical hints may be of service to those who have not yet worked with Velox. The developer is put up in tubes, and simply requires to be dissolved in four ounces of water, and is then ready for use. The tubes are sold at a very small price, and that, like the paper, is subject to a discount to the profession. The manufacturers make no secret of its composition, as that is given in the directions enclosed with the paper, and I have not found any difference between the sold in the tubes and that which I have made myself; and, as many

professionals will prefer to prepare their own developer, I here quote the formula. It stands thus:—

Water .....	10 ounces.
Metol .....	7 grains.
Sodium sulphite, crystals pure .....	$\frac{1}{2}$ ounce.
Hydroquinone .....	30 grains.
Sodium carbonate .....	200 "
(or 400 grains of the crystallised salt.)	
Ten per cent. solution of bromide of potassium (about) .....	10 drops.

The hydroquinone is best dissolved first, and the other materials added afterwards, and no more bromide should be used than will keep the whites clear. An excess, I find, is liable to give a less pleasing colour. On this developer I have not been able to improve when fine rich blacks are desired. If a large quantity of this developer be made up at a time, it should be put into small bottles, filled to the neck, and then closely corked. Under these conditions it will keep for a long time in good working condition. A second formula for a developer is also given, which is as follows:—

Water .....	4 ounces.
Sodium sulphite, pure crystals .....	200 grains.
Amidol (about) .....	20 "
Ten per cent. solution of bromide of potassium (about) .....	5 drops.

I have worked with both, but much prefer the first of the two though both in my hands have given good results.

The manufacturers of the paper lay great stress upon the sulphite of soda used, and I can emphasise the necessity for that from direct experiment. The sulphite should not only be pure when first made, but it should be preserved in that condition. If a small quantity of sulphite of soda, if originally perfect, be kept for a long time in a large bottle or exposed to the air, it becomes partially converted into sulphate. This, beyond loss of preservative action, does no material harm when used for dry plates; but with Velox paper the case is different, as here it is positively harmful, and likely to bring about trouble in the shape of streaks and other markings. It is for that reason that I would advise those who use the paper for the first time to have the tubes of developer, as they will thus ensure having the proper thing, and thereby try the paper under right conditions. The sulphite I have obtained from the Messrs. Griffin is perfect, so is that made by Boake's; but both require to be kept in that condition by preserving it air-tight. When a quantity is bought, I should advise its being ordered put up in four or eight-ounce bottles, according to consumption, so that the crystals are not unnecessarily exposed to the air when each batch of developer is made up. Other developers may be used with the paper, but of that I will say something later on.

With regard to the printing, a second or two to subdued daylight will suffice; but daylight is a very variable quantity, and when a second or two, either way, makes a material difference in the result, I recommend artificial light in preference. If we use a constant light, say gaslight, we can ensure uniform results, and much depends upon correct exposure here, as it does, indeed, with every other process of photography. With an average studio negative an exposure of about a minute, or a minute and a half, at twelve inches from a No. 5 bat's-wing burner, of the cheap regulator form, will be about right. Once the correct exposure is arrived at for a given negative, that for denser or thinner ones is easily judged. All is then plain sailing. Of course, three or four frames may be exposing round the light at the same time. When, however, Velox is worked commercially, I would suggest that the frames be laid flat on a table, above which is a gas burner of the regenerative type, such as the Wenham or the Siemens. We shall then have the frames always at a fixed distance from a practically constant source of light. By this means we shall work under constant conditions of light, and no errors need be made in the exposure. In place of the regenerative burner, a cluster of three incandescent gas burners, with an opal glass reflector above, may be employed. By this system of working, the exposure will, of course, be longer, five or six minutes; but a dozen or more frames,

according to size, may be exposing at a time, so no time will actually be lost. The prints need not be developed at once, as they do not hurt by keeping.

The next point is the development of the picture. The developer may be applied with a camel's-hair brush or with a pledget of cotton-wool, but in commercial work I recommend developing in a dish, using the solution more dilute than given in the formula—say the tube of developing salts dissolved in eight ounces of water instead of four, or the home-made developer diluted with an equal bulk of water before use. With the diluted developer a drop or two more of the bromide solution may be required. When taken from the printing frame, the print should be immersed for a few seconds in water and then transferred to the developer. The image then rapidly appears, and in a minute or two is fully developed. It may appear unevenly at first, but that is of no moment, as the laggard portions quickly overtake the others, and no trace of unevenness is seen afterwards, unless, indeed, the print is over-exposed and the development is stopped too soon. With right exposure the development stops as in the case of platinotype; if it is under-exposed, it is no use forcing the development, I find, with the idea of bringing out more detail. The developing action seems to stop suddenly when it has completed the action set up by the light; and that is one of the great advantages of the paper, as then uniform tints are secured. Sufficient and correct exposure is necessary to begin with, and that is easily secured by using artificial light; by that means any number of prints of equal depth and colour can always be ensured; and that is one of the most valuable properties of Velox. Several prints can be developed in the same solution, provided they be done immediately one after the other; for, if the solution be allowed to stand more than a very few minutes exposed to the air, marking on the prints will result. As the developer is so very inexpensive, I prefer to use fresh for each print.

As soon as the print is developed (which it will be in a minute or so), it is just rinsed in water, or under the tap, and at once put into the fixing bath. That recommended by the makers of the paper is the acid fixing bath of the formula issued with the paper. It is this:—

Hypsulphite of soda .....	16 ounces.
Water .....	64 "

When dissolved, add this solution:—

Water .....	5 ounces.
Sodium sulphite .....	$\frac{1}{2}$ ounce.
Glacial acetic acid .....	1 ounce.
Powdered alum .....	$\frac{1}{2}$ ounce.

Messrs. Griffin also supply the ingredients for this bath put up ready for dissolving. The fixing takes from ten minutes to a quarter of an hour, and it is unnecessary for me to tell professional photographers that, with Velox, as with all other papers, the prints must be kept moving all the while they are in the solution. The washing, in running water, should be about an hour.

With the formulæ and directions for use, issued with the paper, are given causes of non-success; but, if the directions are carefully followed and pure material used, they will be found unnecessary. Still it is well they are given, as then one may see where he has gone wrong.

I had intended to have given my experience in the productions of various reds, sepias, browns, &c., but I find my pen has been running too freely; therefore I propose, with the Editors' permission, to do so in a future article.

E. W. FOXLEE.

#### DEVELOPMENT AFTER FIXATION.

In the current number of the *Photographisches Centralblatt*, Dr. Haschek, writing on this subject, says:—

Kogelmann, of Graz, pointed out some time ago that the image could be developed physically after complete fixation. In September last, Dr. Neuhaus detailed his experiments, and many amateurs have made experiments, and, like myself, with no results, or the negatives were so thin that they were useless for printing. Many experiments were made by me to try and make the development as certain as in the ordinary

way, and a considerable improvement on Neuhaus's original formula was discovered; his developer was—

Distilled water .....	100 c. c.
Ammonium sulphocyanide .....	24 grammes.
Silver nitrate .....	4 "
Sodium sulphite .....	24 "
Sodium hyposulphite .....	5 "
Potassium bromide (ten per cent. solution) .....	8 drops.

For use, Dr. Neuhaus mixed 6 c. c. of this solution with 54 c. c. of water and 2 c. c. of rodinal. With this developer I was never able to obtain a trace of an image.

In place of this I recommend the replacement of the rodinal by 30-40 c. c. of a metol-sulphite solution, such as is used for ordinary work, and is made as follows:—

Metol .....	15 grammes.
Sodium sulphite .....	150 "
Water .....	1000 c. c.

When the plates are placed in the mixture, there will appear, after one or two hours, according to the exposure (and the plate should be strongly over-exposed and well washed from excess of hypo), a positive with all details when looked at, though it is scarcely visible when looked through. After about two hours the image has become sufficiently strong to show distinctly, when looked through, and can be treated further. When looked through, the image appears white, and, when looked at, as a vigorous positive. It should now be well washed and placed in a mercury intensifier, when the image will be first black and white, and at this stage it must be well washed and placed in a ten per cent. solution of sodium sulphite, when it will be intensified and become a beautiful blue-black colour. The plate is then washed and dried.

The above-named developer may also be used for plates in the ordinary way, and an image will be developed in about an hour.

#### THE GLOUCESTER CONVENTION.

THIS year's meeting of the Photographic Convention takes place at Gloucester, in the week July 10th to the 15th. The following preliminary announcement has been issued:—

By the courtesy of the corporation of Gloucester, the use of the spacious Guildhall has been granted for the Convention meetings. The Mayor has consented to open the proceedings, and it is anticipated that at the official reception the executive will be supported by most of the influential residents of the city.

A most attractive programme of excursions has been arranged, including Berkeley Castle, by the special invitation of the Right Hon. Lord Fitzhardinge; Elmore Court, the seat of Sir William Guise, Bart.; Frithern Court, the seat of Sir Lionel Darell, Bart.; the old English village of Frampton, Chepstow Castle, Tintern Abbey, Symonds Yat, Ashleworth, Deerhurst, Tewkesbury Abbey, Highnam, Matson, Hempstead, Cheltenham, Ledbury, Forest of Dean, &c.

Permission has been obtained to photograph the principal buildings in Gloucester, including the magnificent cathedral, the dean kindly allowing members of Convention to photograph the interior at any time during the meeting, except during the hours of Divine service.

The usual Trade Exhibition will be held, and, judging by the applications for space already received, it may confidently be expected that the exhibits of apparatus, pictures, &c., will be unusually numerous.

Special tariffs have been obtained at most of the principal hotels, and at the "Bell" (headquarters) a large room will be reserved for the sole use of members of Convention, whether living at the hotel or not. The Annual Dinner and Smoking Concert, at which ladies are welcome, will take place in the assembly-room of this hotel.

Gloucester is only 114 miles from London (Paddington), and is easily accessible from any station on the Great Western or Midland Railways, and the several lines in connexion therewith.

In connexion with the Convention Mr. Thomas Bedding, by the consent of the Council, has compiled a short history of that institution. It is here given in the belief that it will not only interest members and others, but be instrumental in attracting renewed support to the Convention, which, it will be observed from the appended details of its career, has filled a very useful part in photography during the thirteen years of its existence:

The Photographic Convention of the United Kingdom was founded in the summer of 1886. Its object was to afford facilities to photographers, professional and amateur, for an annual gathering at some suitable town, previously agreed upon, for the purpose of hearing and discussing papers of photographic interest; of holding exhibitions; excursions; a dinner; and other social gatherings. Conventions carried out on this model have for many years been popular amongst the photographers of the United States.

The founders of the Convention, the late Mr. J. Traill Taylor and

Mr. J. J. Bigginshaw, became its first Chairman and Hon. Secretary respectively.

#### DERBY MEETING, 1886.

The first meeting of the Convention was held at Derby in August 1886. The Mayor officially welcomed the members. Haddon Hall, Chatsworth, Dovedale, and Matlock were among the places visited on the excursions. The Convention lasted three days, the attendance numbering forty-six. An exhibition of apparatus was held. The following is a list of the principal papers read: "Success," H. P. Robinson; "Focussing Sailing Ships and other Moving Objects," J. Traill Taylor; "Instantaneous Photography," William Cobb; "Emulsion-making," W. K. Burton; "Daylight Enlarging," Andrew Pringle; "Gelatin Emulsion," A. L. Henderson. An Executive Committee was appointed by the members present.

#### GLASGOW MEETING, 1887.

The Convention was officially welcomed to Glasgow by Bailie Crawford on behalf of the Lord Provost and the municipality. The pictorial display at the Fine Arts' Institute, where the meetings were held, was pronounced "more attractive than that of the Pall Mall Exhibition;" the exhibition of apparatus was also large and interesting. During the week excursions were made to the Falls of Clyde, the Trossachs and Loch Katrine, Loch Lomond and Loch Long, Largs, &c. The dinner was attended by fifty members; the total attendance was about 200. A group of the members was taken at Tarbert.

Among the many papers read the following may be noted: "Finders and Focussers," Lyonel Clark, C.E.; "Elementary Photo-micrography," Andrew Pringle; "Home Portraiture," T. N. Armstrong; "Orthochromatic Photography," C. H. Bothamley; "Film Photography," S. G. B. Wollaston; "The Silver Photo-salts," W. Lang; and "Pretended Photography in Natural Colours." It is interesting to note that Messrs. Pringle and Bothamley at this meeting of the Convention first dealt with the subject upon which they have since become accepted authorities.

#### BIRMINGHAM MEETING, 1888.

The Convention was received by the Mayor at the Masonic Hall, New-street. Addresses at the opening meeting were given by Mr. W. Jerome Harrison (Chairman of the evening), Mr. Traill Taylor (Chairman of the Council), and Dr. Hill Norris. The excursions during the week were to Arley and Bardley-on-Severn, Stratford, Oxford, Kenilworth, Coventry, Warwick, Worcester, Malvern, and Dudley.

The dinner and exhibition were very successful. As evidence of the scientific spirit that animates the Convention, it is interesting to note that at the Birmingham meeting it was resolved, "That it was desirable to have a uniform standard of screws in connexion with camera fittings," and a Committee of five was appointed to consider the adoption of the system of standard lens fittings recommended by the Photographic Society, or to suggest alterations of the system, and to take or indicate such steps as might be necessary for its effective establishment.

Unusual interest attached to the papers read: "Orthochromatic Photography" being treated by Mr. Bothamley and Mr. B. J. Edwards; "Flashlight Work," "Printing-out Platinotype," and "Photo-lithography" being also discussed. The eminent astronomer, the late Rev. S. J. Perry, F.R.S., addressed the members on the applications of photography to astronomy.

#### LONDON MEETING, 1889.

A President of the Convention first appears at its head in the person of Mr. Andrew Pringle, F.R.M.S., who was chosen for the position at the Birmingham meeting. The meetings were held at St. James's Hall, and the custom of delivering a Presidential address was instituted.

During the week there were excursions to the following places: Windsor, Kew, Hampton, and Gravesend. A dinner was held at the Café Royal, and a group of the members was taken at Burlington House.

Mr. Bothamley again addressed the members on the subject of Orthochromatism, and among the other papers were: "The False Rendering of Photographic Images by the Misapplication of Lenses," T. B. Dallmeyer; and "Photo-Mechanical Printing," Thomas Bolas. A report was presented by the Standards Committee, appointed the previous year to consider and report upon the best means of securing uniformity in diaphragms and flanges of lenses and lens mounts. Several recommendations were made by the Committee.

#### CHESTER MEETING, 1890.

The President was Mr. C. H. Bothamley, F.I.C., F.O.S., and the Mayor of Chester welcomed the Convention, in whose honour his Worship held a *Conversazione* at the Town Hall. The Exhibition of apparatus attracted many novelties. During the week there were excursions to Moreton Old Hall, Llangollen, Conway, Bettws-y-Coed, Hawarden Castle, &c.

"Lens Standards," by Mr. A. Haddon; "Photo-micrography," by Mr. Pringle; "Animal Photography," by Mr. Gambier Bolton, were among the subjects dealt with at the evening meetings, at one of which Mr. Friese-Greene read a paper, in the course of which he described "a camera which had been constructed for taking photographs by merely turning a handle, which made a series of negatives on a band of sensitive material at the rate of 600 a minute." This is of historical interest in view of the great development in animated photography that has since

taken place, and singles out the Convention as the scene of the first mention of one of the most notable of modern photographic achievements.

#### BATH MEETING, 1891.

The late William Bedford occupied the Presidential chair, and the Mayor received the members in the Guildhall. Salisbury, Clifton, Bristol, Glastonbury, and Wells were visited during the week. At this meeting Mr. F. P. Cembrano, junior, who subsequently became President of the Convention, was appointed Hon. Secretary, in place of Mr. J. J. Briginshaw, whose business ties obliged him to resign.

At the meetings recent developments in printing processes were described in detail by Mr. Bothamley; the cult of indistinctness was criticised by Mr. W. E. Debenham, and Mr. L. Warnerke read a paper on a series of proposed International Standards.

#### EDINBURGH MEETING, 1892.

Presided over by Mr. George Davison, the Edinburgh meeting of the Convention was officially welcomed by the Lord Provost of the City. The papers read by Mr. H. P. Robinson and Mr. Arthur Burchett treated of the pictorial side of photography; Mrs. C. Weed Ward, Mr. Howard Farmer, Dr. C. L. Mitchell, and Mr. F. M. Sutcliffe also read papers. Among the interesting places visited on the excursions were Melrose and Dryburgh, Newhaven, St. Andrew's, Cramond Bridge, &c.

#### PLYMOUTH MEETING, 1893.

Again was the Convention the recipient of a compliment at the hands of the municipality, the Mayor of Plymouth welcoming the members at a reception in the Athenæum. Mr. George Mason, of Glasgow, was the President of the year. Excursions were made to Tavistock, to Mount Edgecombe Park (by kind permission of the Earl of Mount Edgecombe), Totnes, Dartmouth, &c.

The Mayor of Devonport also received the Convention. The papers submitted were of remarkable interest. The properties of the Zeiss Anastigmatic Lenses were exhaustively described by Dr. Rudolph of Jena, and Messrs. Hurter & Driffield gave an exposition of their system of measuring the speed of plates. The names of W. K. Burton, E. J. Wall, and the Rev. F. C. Lambert appear among the readers of papers.

#### DUBLIN MEETING, 1894.

The eminent optician, Sir Howard Grubb, F.R.S., presided over the meeting, and the Lord Mayor welcomed the members in the Library of the Royal Dublin Society, a *Conversazione* being subsequently held in the Science and Art Museum building. During the week, very successful excursions were made to Monasterboice, Drogheda, Powerscourt, &c., and the Lord Mayor gave a garden party to the members at his house at Killiney. At this meeting the Convention for the first time was declared to be in a satisfactory financial position, having a credit balance of 50l.

Among the readers of papers was Dr. Joly, who first publicly outlined his colour process at the meeting of the Convention. The President's paper was a valuable one on optical matters, and other subjects dealt with were the influences of temperature upon the sensitiveness of dry plates, a Photographic Sextant, Astronomical Photography, and the uses of Photography in Medicine.

This was a most successful gathering, and the membership reached a total of 270.

Mr. R. P. Drage became Hon. Secretary of the Convention at the close of this meeting.

#### SHREWSBURY MEETING, 1895.

The Tenth Meeting of the Convention was presided over by Mr. A. Haddon, and the Mayor received the members in the Guildhall. During the week the Convention was entertained by Mr. H. D. Greene, Q.C., M.P., Member for the Borough, and the principal excursions were to Bridgworth, Stokesay, Church Stretton, Ludlow, Buildwas, and Wenlock Abbeys.

Mr. Cembrano, the late Hon. Secretary, was presented with a hand camera in recognition of his services. The hearty hospitality of its Shropshire hosts and the beauty of the scenery on the excursions were highly appreciated by the members of the Convention. The group contained 130 portraits of members, many of them ladies. Colour photography formed the subject of papers by Mr. E. J. Wall and Mr. Child Bayley. Mr. Alfred Maskell dealt with pictorial photography, the old and the new.

#### LEEDS MEETING, 1896.

Mr. H. P. Robinson, the doyen of English photographers, occupied the Presidential chair, and he kindly organized a special Exhibition of Pictorial Photography, which was held in the Library of the Museum. An official reception was tendered to the Convention in the City Art Gallery. Bolton Abbey, Fountains Abbey, and York were the principal scenes of the excursions, which were largely attended and were highly successful. The principal paper read was one on "The Fixing and Washing of Prints," by Mr. Haddon. Radiography and Orthochromatism were also treated of.

#### GREAT YARMOUTH MEETING.

The President was Mr. Cembrano, and the Mayor officially received the Convention. Excursions by water were made to Lowestoft, Norwich, Salhouse Broad and Oulton Broad. The subjects of the papers were:—

"Methods of Control and their influence on the Ultimate Development of Artistic Photography," by Mr. A. Horsley Hinton; "The Points of a Lens," by Mr. Dallmeyer; "Half-tone," by Mr. Gamble; "Photography in Natural Colours," by Mr. Wall; and "The Strength of Hypo Solution and Time of Immersion for Fixing Albumenised Paper," by Messrs. Haddon and Grundy. The latter paper was the outcome of a grant in aid of research voted by the Council.

At this meeting the Dansac-Chassagne process of so-called photography in natural colours, by "selective colour absorption," was publicly demonstrated to members, who had an opportunity of observing that it failed to sustain the claims made on its behalf.

In addition to the usual group, a cinematographic picture of members was taken by Mr. E. P. Prestwich, and shown at one of the evening meetings.

Mr. Drage having resigned the Hon. Secretaryship of the Convention, Mr. F. A. Bridge was elected to fill the vacancy.

#### GLASGOW MEETING, 1898.

The Convention met for the second time at Glasgow, and was presided over by Mr. John Stuart. The chief excursions were to Ayr, the Forth Bridge and Edinburgh by train, down the Clyde and to Loch Lomond by water. An afternoon reception was given to members in the Municipal Buildings. The Presidential address was a comprehensive one, and, besides photography in natural colours, development, the speed of plates, and the gum-bichromate process were discussed at the evening meetings. The pictorial exhibition was large and interesting, the trade exhibits and local professional photography being noticeably good.

The membership reached a record total of 328.

#### HOME PORTRAITURE.

At the last meeting of the Oxford Camera Club Miss Acland gave her promised paper on "Home Portraiture." The beautiful portraits which Miss Acland had shown at the Club Exhibitions made the members anxious to learn her methods, and there was a large attendance. The President (Sir W. J. Herschel, Bart.) was in the chair, and Miss Acland's father (Sir Henry Acland, Bart.) was also present. The paper was a very comprehensive and able one, and was listened to with great attention, the beautiful examples of portraiture thrown on the screen by Miss Acland's brothers, who manipulated the lantern, elicited much applause. Miss Acland said the amateur, if he possessed technical skill, ought to find it easier to produce good portraits than the professional, as his sitters would be less constrained.

One of the first difficulties was the getting rid of all ideas of colour, and regarding the subject simply as a study in black and white. The proper distribution of light and shade was very important, and, by the kindness of the Curators of the University Galleries, Miss Acland was able to show three of Sir Joshua Reynolds's studies in black and white. These were carefully examined and criticised; they gave a vivid example of the importance of this part of the subject. The second difficulty was that of properly lighting the subject, especially in the absence of a properly equipped studio. Outdoors a shady place should be chosen, where the light is cut off on one side, and care must be taken that the eyes of the sitter do not face a strong light. It was a great advantage to use a screen, which can be easily made by stretching blue tarleton over a hoop fastened to a bamboo pole. It was mentioned that Mrs. Cameron used to place her sitters inside a barn with large open doors.

For indoor portraiture a long room should be chosen if possible, with two windows on the north side. The sitter should be placed opposite one window, about six feet from it, and, should it be a high one, the blind should be drawn a little to cut off the top light, or a piece of muslin at the top to diffuse the light would be better. Should the window reach to the ground, it should be covered to about the height of the sitter's shoulders. The second window, near where the camera stands, is useful to diffuse the light, and need not usually be interfered with. Should the shadow side appear too dark, a white blanket should be hung a little distance from the sitter; a blanket gives a softer reflection than a sheet or table-cloth. If a strong effect is required, concentrate all the light on the sitter by drawing the curtains of the second window. It was recommended that, before attempting portraits, experiments should be made on a bust in different positions, making careful notes of the effect of the light.

Miss Acland showed a remarkable example in four studies of a bust of Dante. It was seen that the variations of light and shade on the bust produced quite a marked alteration in the expression of the face. In one, Dante appeared with his usual lugubrious expression, while in another he appeared to be smiling; and one example was shown in which all expression had been eliminated by extensive retouching, so much in vogue. The question of backgrounds required much consideration. Rubens once said to a young painter that, if he properly understood backgrounds, he required no instruction from him, and it was admitted by all painters to be very important.

The amateur had not much choice; but a blanket made a good background, or a plain sheet on a roller could be purchased, it should be not less than eight feet high for standing figures. Slate was a useful colour, and Miss Acland showed how the colour of a slate background could be

varied by placing it in different lights almost so that in some cases it would appear quite white, and in others quite black, and by placing it at an angle it could be shaded off on one side. When the figure was beautiful it might stand out boldly, but, when this was not the case, it should be partially lost in the background. Ladies are more difficult to take than gentlemen, and particular care should be given to the posing; to make a graceful pose, the head should not be in a straight line with the body. It is often a help to tilt the camera down a little without using the swing back, so as to bring the different parts into one plane. The hands required special care; the wrists should be bent so as to produce a shade on it, to mark it, or it will not be seen. Few faces are sufficiently symmetrical to be taken full, and Mr. Debenham's rules, as to which side of the face should be taken, were quoted from *THE BRITISH JOURNAL OF PHOTOGRAPHY* for June 24 last. An expensive camera and lens were not a necessity, although, of course, when they could be had, so much the better; a good portrait was shown which had been taken with a guinea pocket Kodak.

In conclusion Miss Acland deprecated the idea that the photographer, however skilled, could ever compete with the artist in taking portraits: "Sun pictures can only be a means of elevating taste by rendering us more familiar with nature's infinite beauty, and by educating the eye by presenting her transient forms and effects imprinted by her own hand without fear or favour, causing true art to be better appreciated and more widely understood."

Many beautiful examples of portraiture taken by Miss Acland were thrown on the screen. These were, in most cases, friends and visitors at her own home, and their easy, unconstrained expression fully bore out what was said at the beginning of the paper as to the advantages over the professional in this respect. The portraits shown included Lord and Lady Salisbury, the late Mr. Gladstone, Mr. Ruskin, the Bishop of Oxford, Lord Kelvin, Sir Wm. Richmond, Prof. Max Müller, the late Dean Liddell, Miss Acland's father (by her uncle, the late Sir Thomas Dyke Acland), Mr. Brunel, Dr. Billings (Deputy Surgeon-General of the American Army), and the President of the Club, Sir W. Herschel.

At the close of the lecture a hearty vote of thanks was given to Miss Acland for her valuable paper, and some time was spent in examining the examples of portraiture by Miss Acland. Valuable Daguerrestypes, &c., and also a portrait in natural colours taken by Mr. Ives for the President, and which was shown in the photo-chromoscope. This was said to be the first portrait ever taken in natural colours.

#### AT THE CAMERA CLUB.

THE history of Renaissance architecture is a subject which lends itself to illustration by photography, and when it was known that such a competent lecturer as Mr. G. A. T. Middleton had promised to tackle the story, a large attendance of members of the Club was assured, for Mr. Middleton has again and again given evidence of his fitness to discourse upon matters architectural, which he does without notes and with a surprising fluency, considering the difficulty of the subject in hand; and his photographs, if not always technically perfect, are always taken with a view to illustrate some truth, or to show some little detail which he has unearthed, it may be, in some old-time Continental town, a detail which many would pass unnoticed.

Mr. Middleton's first examples were taken from the beautiful city of Florence, in whose palaces, churches, and public buildings generally, are to be found so many of the choice treasures which former artists and sculptors have left as evidences of their genius. Here we were shown a fine photograph of the well-known duomo of the cathedral, begun in 1447, and finished by Brunelleschi. To this man may be ascribed the Renaissance so far as Italy was concerned, for he went to Rome, saw the ancient buildings there, and, adapting their style to meet later requirements, went back to Florence and completed the cathedral there. He was a goldsmith by training, and, like many of that trade, became later on an architect; to this circumstance common to the time we owe much of that elaboration and fineness of ornamental design which we find upon so many early buildings, resulting in a richness which delights the photographer as much as any one.

Thus the Renaissance first arose in Florence by the genius of one man. Other buildings in the same beautiful city show plenty of evidence that the lesson was taken to heart by other architects, one of the most beautiful examples being a palace, which outside was stern and prison-like in appearance—for the exigencies of the time required that it should be a stronghold as well as a home, while inside all was of the greatest richness and delicacy. In Rome the Farnese Palace was selected by the lecturer as an example of Renaissance work; but the movement met with no support there until the sixteenth century. The interior of St. Peter's gave an opportunity of comparing that magnificent building with our St. Paul's in London, which, as is well known, was designed on the same model. It was the work of Michael Angelo, a painter, and for this reason he had given, in designing it, every opportunity for the introduction of paintings and mosaics upon its walls.

The third great city which came under consideration was Venice, and of which beautiful views of the Rialto, the Bridge of Sighs, &c., were thrown. Valuable lessons were drawn by the lecturer from the details of

each building, an advance in taste being indicated here and a retrograde step there. Decadence was shown in the building at Genoa by the introduction of pillars which had nothing to support, and buttresses where their aid was not required.

Many fine examples of French architectural work were projected on the screen, to show that Gothic had taken a much firmer hold in France than it had in Italy, and had resulted in masterly work. In these pictures it became apparent from what source our modern English architects have drawn much of their inspiration, and in some cases had improved upon the original works.

It was natural that Renaissance should quickly get from France to Belgium, and many fine examples of Belgian work were shown. Some of them were from casts; and the lecturer took the opportunity of reminding his readers that one of the finest collections of architectural casts in the world was at the Crystal Palace, Sydenham. Unfortunately, he added, it was difficult to get permission to sketch or photograph them.

There was a curious flaw in one of the lantern pictures shown here. It was a picture of a pulpit, supported by life-sized sculptured figures, one of which was holding out his upturned hand. Exactly on the fingers, as if balanced there, was a comet in the cover glass, looking just as if the saint had taken off his halo as an ordinary mortal would his hat.

In Germany, and notably at Nuremberg, we were shown how Gothic feeling was combined with Renaissance work with the happiest results; and it was with interest that we learnt that the authorities in this quaint old town were careful, in rebuilding where needed, to carry out all new work according to old traditions. Another old German town, that of Rothenburg, was happy in the circumstance that only one new building had been erected within its walls for a century past. Mr. Middleton strongly advised his brother photographers to visit the place.

With regard to modern work, the Germans are scientists rather than architects, and show a tendency to stiff and formal reproductions of classic models. They miss the spirit of Renaissance and give us only its dry bones. Thus finished a profitable evening at the Camera Club, under the chairmanship of Mr. Bros.

On Monday, the 6th inst., there was no lecture, but, nevertheless, the members spent an enjoyable and strictly photographic evening, for various manufacturers and dealers had been invited to show any novelties they might be introducing. It was a happy thought on the part of the Hon. Secretary to arrange such an evening as this, which turned out to be quite a little exhibition in itself. Some of the exhibitors were wise enough to send representatives to demonstrate the virtues of their apparatus, while others were content to forward written accounts of the goods which they sent, to which attention was called by the Hon. Secretary.

Messrs. W. Butcher & Son, of Blackheath, and Mr. Tylar, of Birmingham, showed many little novelties in the shape of small things of great use to photographers. The photographic outfits of the former firm are most compact and wonderfully cheap. Mr. Tylar's isochromatic screen discs to fit on any lens attracted a good deal of attention, as did also his Cascade Washer—a series of metal trays one above the other, so arranged that the water from a tap entering at the top will effectually leave the plates lying in all the others.

The Platinotype Company exhibited some new wood and metal cases for the preservation of their paper. At the lower end of the cylindrical case is a receptacle for calcium chloride, and at the top a cleverly constructed air-tight lid. This lid fits into a recess, and pressure upon a central knob causes an indiarubber band to press outwards, and make an air-tight and damp-tight joint.

The representative of Messrs. Gaumont & Co. exhibited a well-made form of cinematograph apparatus, which he claimed to be almost silent in action, a claim which no representative was present to substantiate. It was unfortunate that no film was passed through the machine, for the statement was made that, should the celluloid by any accident be ignited, the fire could not spread beyond the picture at the time in front of the lenses. This is a very important advantage; but, in the absence of a demonstrator, it was impossible to see how this immunity from danger was secured. This firm also showed a neat form of opera-glass camera—Photo-Jumelle—and mentioned that they were agents for the Artigue carbon paper.

The Eastman Company's representative exhibited the newest forms of daylight-changing Kodaks, and showed some fine specimens of pictures taken on their recently introduced Dekko paper. This paper is apparently coated with a slow chloride emulsion, for it can be handled with impunity by ordinary lamp-light. The specimens shown were full of delicate gradation and fine detail. This paper will not only be valued by amateurs, but by professionals also, for it offers a ready means of securing rapidly a proof print without the necessity of toning.

Messrs. Ross sent a representative to exhibit many interesting pieces of apparatus, each of which showed ingenious design and very beautiful finish. The "Combination" lantern, which can be used for enlarging, for ordinary projection, and for scientific demonstration, is a very fine instrument, and, when employed with the "Radiant" jet, a magnificent light is obtained. The smaller lantern, known as the "New Model," is also worthy the attention of lanternists, for it exhibits more than one entirely new feature. It has, for example, no body, in the ordinary sense of the term, but in its place a metal box about three inches in depth, the

sole use of which is to contain the lime cylinder. The apparatus is, in other respects, wonderfully compact and very cheap. The projection arc lamp, which possesses many good points, was also shown by Messrs. Ro-s's representative, as well as other novelties.

This exhibition of photographic apparatus excited a good deal of interest among members of the Club, and many questions were asked and replied to. The Hon. Secretary expressed his pleasure at seeing so many exhibits, and said that the Club were much obliged to the various firms who had brought these novelties to their notice, and to the gentlemen who had acted as demonstrators.

#### YORKSHIRE PHOTOGRAPHIC UNION.

A MEETING of delegates, in connexion with this movement, was held at Bradford Grammar School, on Thursday, March 2.

Mr. Godfrey Bingley was voted to the chair, and there were present Messrs. Percy Lund and Alex. Keighley (Bradford Photographic Society), Fred T. Coupland (Yeadon and District), Harold M. Briggs (Wakefield Photographic Society), James Laylor and J. Crossdale Coultas (Leeds Photographic Society), Thomas Heaps and Mr. H. Hainsworth (Keighley and District), W. H. Atkinson (Batley), F. W. Rhodes (Heekmondwike), J. F. Ashley (Rodley), J. W. Holland and Lionel Dickinson (Halifax), J. H. Georgeson and A. H. Ormerod (Brighouse).

There was nothing of very special interest that transpired, a good part of the evening being occupied by a further discussion in regard to the provisions relating to the scheme dealing with lectures and lecturers.

It was announced by the Hon. Secretary (*pro tem.*), Mr. Ezra Clough, that the following societies had already joined the Union: Batley Photographic Society, Beverley, Bradford, Brighouse, Halifax Camera Club, Heekmondwike Photographic Society, Hull, Keighley, Leeds, Rodley, Sheffield, Wakefield, Scarborough, Sheffield Optical Society, and Yeadon Photographic Society.

The Chairman said he thought they ought to consider the return fairly satisfactory in the present state of the proceedings.

The Hon. Secretary stated that various societies had paid their subscriptions, but as yet it had been impossible to forward official receipt forms.

The first business was the further consideration of the constitution of the Union, as already published.

Mr. Percy Lund pointed out the inadvisability of making that night what he described as "cast-iron" rules. They should devise something for their general guidance, which could be varied at any time as necessity arose and experience directed.

It was decided that the membership be: 50 or less, 10s. per annum; 100 or less, 15s.; and 20s. for all above that number.

Mr. Rhodes put forward a motion to the effect that the subscription be 30s. for associations above 100; but this was defeated.

A lengthy discussion took place with regard to Associates and their standing in the Union, and ultimately it was resolved on the motion of Mr. Lund, seconded by Mr. Coupland—"That the Committee may also add to their number five Associates who shall not already be representatives or members of any society attached to the Union."

Mr. Georgeson thought it was a mistake to have a Committee consisting of twenty-five. A smaller Committee would be more workable.

Mr. Ashby was of opinion that the suggested Committee was not too large.

Mr. Clough favoured the appointment of as large a Committee as possible.

The question of the interchange of lecturers gave rise to a lengthy debate.

Mr. Briggs doubted if the suggested course of action would work. (Each society in the Union shall be allowed two voluntary lectures each season, and in addition an extra lecture for each approved lecturer, &c.)

Mr. Clough asked, if there were societies in the Union which had no lecturers at all, how were they going to be provided for?

Mr. Briggs: It appears they would get two.

Mr. Clough: Where are they to come from?

Mr. Briggs: I think it is a mathematical absurdity.

Mr. Ormerod thought it was a mistake. If the small societies could get lecturers, they ought to have them, apart from supplying lecturers themselves at all.

Mr. Lund expressed the opinion that the matter should be left to a sub-Committee of the Union, to make out a list of suitable lectures.

The Chairman said it seemed to him it would be the best place for the Union to get a list of likely lecturers from the various societies, and submit the names to the societies for consideration. The great difficulty would be to give the societies a list of gentlemen who would be willing to give lectures. Were the lecturers to deal with the societies themselves? This was the one question upon which a certain society had disagreed with them. One gentleman had said to him, "Is the Committee of the Union going to say where lecturers are to go to? If they are, I shall object. I think lecturers ought to choose their own locality." It ought to be left optional. The names of willing lecturers ought to be given, and the various associations apply to them direct.

Mr. Dickinson thought the best plan would be for the Union to draw up a list of the available lecturers and submit the list to the secretaries of

the various associations, who could afterwards meet and mutually arrange their programmes.

Mr. Briggs said the idea of an interchange of lecturers was an admirable one, especially as regarded the smaller clubs. He did not think there would be any difficulty in getting any lecturer to go to any part of the country.

The Chairman: Possibly it might be practicable to group the districts.

Mr. Coupland asked what constituted an "approved" lecturer. If a man was a good lecturer, he would have an approved reputation from somewhere. It seemed to him it was not necessary a man should have a good reputation, but, at the same time, he mustn't have a bad one. They ought to classify the lecturers as "high flown," "first class," and "elementary."

Mr. Lund agreed that it was absolutely necessary the Union should draw out some plan as to the lecturers at their disposal—their qualification, and the districts they were prepared to cover.

Mr. Heaps hoped it was not intended to alter the arrangements with regard to lecturers, as certain societies had joined on the strength of existing arrangements.

Mr. Clough pointed out that they could go no further until they knew what the lecturing staff was likely to consist of. They must not forget that it was very materially with regard to the question of lecturers that the Union would stand or fall.

Mr. Briggs intimated that, unless the lecturer question was satisfactorily settled, the Wakefield Association would have to reconsider their position.

Mr. Heaps strongly supported Mr. Briggs's view of the matter.

The Chairman pointed out the danger there was in promising something they might not in the long run be able to fulfil.

Mr. Hainsworth suggested that the discussion, extending over nearly an hour, had been of no use.

Ultimately it was decided to postpone the matter for further consideration.

On the motion of Mr. Briggs, it was decided "that the constitution stand for twelve months, subject to any alteration made at any general meeting."

It was resolved that the whole of the existing delegates form the Committee of the Union, and that circulars be sent to the members, asking them to give their votes for the various officers required in the Union.

It was decided to hold the next meeting on April 13.

#### MAGNESIUM CARTRIDGES.

THE little magnesium cartridges at present in the market have been found so useful in practice that the following description of the method of their preparation, due to the inventor, Mr. York Schwartz, of Hanover, will, doubtless, be interesting: When finely powdered metallic magnesium is mixed with a chlorate, or a picrate, or a permanganate, or similar substance easily delivering oxygen, compounds are obtained which, on ignition, burn rapidly, evolving a great volume of light of high optical and chemical intensity. Such mixtures are largely used for the purpose of photographing at night, or in places where daylight has no access. Serious objections, however, may be raised against their use, for

1. They are more or less explosive, and sensitive to friction or concussion.
2. In combustion they give off a great quantity of smoke.
3. They easily deteriorate under the influence of moisture.

I have now found that mixtures producing the same, if not better, effects as regards the illuminating power, and being in all other respects far superior to the compounds described above, may be obtained by mixing:—

Finely powdered magnesium and

A. Finely powdered silicic acid (by preference the natural material known as "infusorial earth").

Or, B. Finely powdered boric acid.

Or, C. Finely powdered anhydrous sulphate of lime.

Or, D. Finely powdered sulphate of baryta.

Or, E. Finely powdered anhydrous sulphate of magnesia (by preference the calcinated mineral known as "Kieserit").

Or, F. Finely powdered sulphate of strontian.

In suitable proportion, by preference equal parts of magnesium and one of the substances named. Instead of only one of these substances, A, B, C, D, E, F, several of them may be used in composing the mixture, so as to arrive, for instance, at the following formula:—

Finely powdered metallic magnesium, 1 part.

Finely powdered silicic acid,  $\frac{1}{2}$  part.

Finely powdered boric acid,  $\frac{1}{2}$  part.

Finely powdered anhydrous sulphate of lime,  $\frac{1}{2}$  part.

Finely powdered sulphate of baryta,  $\frac{1}{2}$  part.

Finely powdered anhydrous sulphate of magnesia,  $\frac{1}{2}$  part.

Finely powdered sulphate of strontian,  $\frac{1}{2}$  part.

While all these mixtures have in common that they are not explosive, not sensitive to friction or concussion, deliver in combustion only very little smoke, do not easily deteriorate under the influence of moisture, burn very rapidly, instantaneously, emit in combustion a great quantity

of light of highest optical and chemical intensity, mixtures A and B offer yet a special feature. When compressed in a tube of suitable non-combustible material, one end of which is closed, the other being open but contracted, by preference so as to form a narrow slit, and then, when the contents of the tube are ignited at the open contracted end, a broad and long sheet of brightest light, with scarcely any smoke, is emitted. In this case the combustion is not instantaneous; the emission of light lasts for some time, and may be prolonged at will by adapting the size and proportions of the tube to the purpose for which the light is to be used.

#### NOTES FROM THE WEST OF SCOTLAND.

THE action against the Shettleston Camera Club, which has caused so much interest in photographic circles throughout the United Kingdom, has been advanced a stage in the Sheriff's Court of Glasgow, when, on the diet for the adjustment of pleas, the agent for the pursuer made an application for the grant of further time to enable the pursuer to collect additional evidence. This the Sheriff granted, but we understand the case comes into Court again very shortly, and, if it goes to proof, it will be tried before a jury.

It is gratifying to be enabled to announce that at last there is something like a revival of the old interest taken in the proceedings of the Glasgow Photographic Association. The new Hon. Secretary, Mr. Macdonald, is sparing no pains to bring this Society into what may be termed a new lease of life, and Mr. Lindsay Miller's recent lecturette, with the old Chairman and President, Mr. W. Lang, F.C.S., drew a crowded audience. This contrasts favourably with recent meetings, and promises well for the future.

Mr. William Verel of the Albion Albumenising Company, has just finished the construction of a very clever piece of apparatus in the shape of a changing box, intended for the exposure of plates of any size, from the modest quarter-plate up to the largest of, say, twelve by ten dimensions.

By an exceedingly simple movement a plate is separated from a batch, exposed and then caused to locate behind all the others in the magazine. The apparatus is of very small bulk, and the simple and certain action of changing the plate is quite surprising.

The Messrs. Lizars are also bringing out a clever new magazine camera that carries both films and plates, and it is gratifying to note that Mr. Matthew Ballantyne, who has gone to the Canaries to recruit his health, is making satisfactory progress, and expected home shortly quite convalescent.

#### THE SOUTH LONDON EXHIBITION.

THE Tenth Annual Exhibition of this Society is noticeable for the fact that the work contributed by the members is so good and varied that it may fairly be considered equal to the section that is derived from outside support. This progressive tendency on the part of the South London is shared by such veteran exhibition-holding societies as the Hackney and the Birmingham. In course of time we anticipate that the levelling-up movement that is visibly going on will become so general that open classes will no longer be necessary to ensure the numerical or artistic success of a society's exhibition, and that just as champion classes have ceased to exercise their former magnetism on many first-rate photographers, so those sections that are still open to outsiders will fail to possess that significance that once attached to them. Observation convinces us that many causes are at work in this direction, and not the least of them is the undoubted fact that pictorial photography has reached a stage which does not easily admit of any marked advance or improvement, and that the teachings and examples of the last ten or a dozen years have produced a numerous crop of workers fairly equal in ability to make pictures by the aid of photography. Both these causes, or rather effects, make themselves apparent in a cohesive society like the South London, and thus the necessity for relying upon an open section to form the main attraction of its Exhibition is gradually disappearing.

There is another and a paramount reason why all well-wishers of photography should rejoice at the very agreeable tendency we have just glanced at, and that is the support it unquestionably lends to the aspirations of those who desire to see the abolition of the medal system. It will, no doubt, be a very long time before medals at exhibitions are done away with; but one of the most potent forces at present operating to bring about that end is the gradual growth of the custom of societies relying entirely on their own members' work for exhibition and distinguishing the best photographs shown by a certificate, or not at all. The cumulative influence of the slow decline of open classes is working in the same direction, and we quite confidently look forward to the time when the dignity of exhibition photography will no longer permit itself to be affronted by the silly and unsatisfactory system of medal-bestowal, which like all abuses is dying such a hard and prolonged death.

But, to escape from the discussion of abstract questions, let us congratulate the South London Society on its present Exhibition. It suffers,

perhaps, both in the members' and the open sections by reason of the admission of a not inconsiderable number of mediocre photographs, the presence of which, in the members' classes, may, however, be excused on the ground that it is a good thing to let the beginner, in picture-making, see for himself how his work stands by comparison with the production of older workers. While fully maintaining its reputation for architectural work, the Society is happy in the possession of several members who can produce distinctly high-class portrait and figure studies, and of the new men who shine in both these branches we have every hope of hearing great things in the future.

Class A (Members' Portraiture, and Figure Study, including Animal).—Mr. A. Flint shows some delightful child portraits, expression, pose, and lighting being of the happiest. He well wins his award. Mr. E. Matthews betrays marked ability in a charming and delicate little portrait, *Dear Dollie*, and a very good portrait of a young lady, *Memories*, the reflective expression being well suggested. A nun subject (No. 20) is marred by the line separating the shadow of the hood from the brightly lit face, cutting the head, as it were, in two. We liked Mr. W. T. Tollett's animated *Flower Girls*, a street-view at Piccadilly-circus. The artist evidently has an eye for pictorial effect in a London street, and the ability to photograph it. It is full of life and natural movement.

Class B (Architecture).—This class is, of course, replete with first-rate architectural studies. The successful competitors show singularly delicate and well-graduated pictures. A word of praise should be passed to Mr. C. Churchill for his capital renderings of statuary.

Class C (Landscape, Seascape, and Scenery).—The work in this class is very mixed; it would have stood considerable weeding out. Mr. E. H. Lamb again secures notice with *Waning Day* and *Homeward Bound*. The exhibitor's name is new to us, but he evidently possesses great pictorial power. Out of such an unpromising theme as *Evening on Yarmouth Denes*, Mr. T. Moyser makes a very pleasing and sentient photograph; so, too, Mr. T. A. Price, with a view of an *Old Farm at Sunset*, secures a very happy result. *A Misty Feeling in the Air* (bronze) well suggests the effect pointed at in the title. Mr. and Mrs. Welford show beautiful landscape work, and the former, in *The Top of the Hill*, is represented by a vigorous and original photograph. We like the work of Mr. Welford and others at this Exhibition which shows traces of breaking away from the imitative tendency that has recently attacked many well-known exhibitors.

Class D (Hand-camera Work).—This is neither better nor worse than most hand-camera classes. The work of Mr. and Mrs. Welford is certainly the best shown, the former's pastoral scenes being hand-camera work of a very high order indeed. For the "usual thing" in snap-shots, with which the class abounds, it is late in the day to feel or express admiration.

Class E (Beginners since January 1) of course contains a few horrors; but Mr. E. B. Collins (photographs of panels at Windsor), and a well-meant illustration of *The Ploughman Homeward Plods his Weary Way*, and Mr. F. Wise, redeem the class from something below mediocrity.

In Class G (Members' Pictures previously Medalled), besides a graceful head study by Mr. Mathews, *Naomi*, there are some good land and seascapes by Messrs. Lamb, W. F. Slater, Welford, and in Class H (Open Pictures previously Medalled), Mr. W. F. Bannister has a fine study of *Sunlight and Shade*, the deep dark frame heightening the effect. Mr. H. E. Brightman's representation of *The Miser* is most dramatic and realistic. Not that we personally know anything of such unpleasant people as misers, but that Mr. Brightman conveys very successfully the traditional way in which the poor creatures gloat over their gold. The gentleman studying *An Interesting Paragraph*, has supplied Mr. W. Illingworth with the opportunity of achieving a highly effective bit of genre work. *Polly*, by Miss Weil, is a delightful bit of girl portraiture.

Class J (for Pictures not previously Medalled), contains about 100 of the 461 pictures hung. *Convalescent*, a lamp-light study of a reclining lady by Mr. Thornley Brooks, is excellent in naturalness of effect and arrangement. A series of capably executed portrait studies comes from Messrs. John Chaffin & Sons, and we congratulate the firm on the very great advances their work shows here. *Undine* (a fanciful study by G. B. Cowen) and Mr. Dowden's cleverly lit *Normandy Peasant* arrest attention, and Mr. Howard Esler's panel reproductions show flawless technique. *Worn Out* is the photograph of a pathetic-looking old man which secures Mr. Illingworth the silver medal. It is well deserved, for the photograph is very powerful in naturalness of effect. Mr. Pirie Macdonald's portrait studies are very striking; they would have been more appreciated if a printing process better calculated to suit such subjects had been chosen. A few gum prints are shown, but they are not satisfactory productions—they have a crude effect of stipple work. The sooner this unfortunate process is killed outright the better. On the other hand, Mr. W. E. Smith shows a gum print in colours of *Pear and Apple Blossoms* which is rather effective.

The wall space at the South London Exhibition is very great, and the public likes a lot for its money. It gets it here. Personally, however, we should have unhesitatingly rejected half the photographs that are hung. Nevertheless, there is some remarkably good work shown, and the Society is to be complimented on the support it receives both from within and without.

The Judges were Messrs. Hinton, Hodges, and Pringle, and their awards were:—

MEMBERS' CLASS.

CLASS A.—Silver medal, No. 5, Mr. A. Flint; bronze medal, No. 19, Mr. E. Mathews.

CLASS B.—Silver medal, No. 79, Mr. E. H. Lamb; bronze medal, No. 89, Mr. S. W. Whiteman.

CLASS C.—Bronze medal, No. 147, Mr. C. W. Walker.

CLASS D.—Bronze medal, No. 247, Mr. W. T. Tollett; bronze medal, No. 252, Mrs. J. A. Welford.

CLASS E.—Silver medal, No. 283, Mr. E. R. Collins; bronze medal, No. 291, Mr. F. Wise.

CLASS F.—Silver medal, No. F 1, Mr. E. R. Bull; bronze medal, No. 9, Mr. W. Page; bronze medal, No. 11, Mr. F. Smith.

CLASS G.—Gold medal, No. 310, Mr. E. H. Lamb.

OPEN CLASSES.

CLASS H.—Gold medal, No. 348, Mr. W. A. Fraser; silver medal, No. 340, Mr. F. W. Bannister; bronze medal, No. 321, Mr. W. F. Slater.

CLASS J.—Silver medal, No. 416, Mr. W. Illingworth; bronze medal, No. 422, Mr. A. J. Jeffreys.

CLASS K.—Silver medal, No. 13, Mr. C. H. Oakden; bronze medal, No. 6, Mr. E. R. Bull.

CLASS L.—Silver medal, No. 14, Mr. A. E. Smith; bronze medal, No. 18, Mr. G. Thompson.

CLASS M.—Silver medal, No. 7, Mr. F. Goddard; bronze medal, No. 9, Mr. C. H. Oakden.

TRADE SECTION.

BEST TRADE EXHIBIT.—Silver medal, Messrs. Spiers & Pond, Ltd.

## Our Editorial Table.

BACKGROUND DESIGNS.

The Scenic and Decorative Artists' Association, 7, Percy-street, Tottenham Court-road.

From this Association we have received a series of reproductions of the designs to which the backgrounds they are supplying are executed. A speciality is made of pictorial effects in the styles of Romney, Sir Joshua Reynolds, Gainsborough, &c., and in these attempts to escape conventionality the Association appears to us to be extremely successful. The designs, both exterior and interior, are conceived in the best taste, and we should think that studio work accomplished with the assistance of these excellent backgrounds would secure the highest admiration.

CHEMISTRY FOR PHOTOGRAPHERS.

By CHARLES F. TOWNSEND, F.C.S., F.R.P.S. 158 pp. Price 1s.  
London: Dawbarn & Ward, 6, Farringdon-avenue, E.C.

This is the second edition of a volume which we can recommend for a place on the photographer's book-shelf. The title might, perhaps, lead some to suppose that Mr. Townsend only treats of photographic chemistry *per se*, that is to say, the characteristic properties and reactions of the chemicals used in the various processes. But this is not so. What he does is to take the reader through a brief practical explanation of those processes, the chemical considerations so involved being at the same time elucidated and made plain to the reader. This is a capital way of familiarising photographers with the underlying theories of the work they perform in developing, printing, toning, and other operations. There are fifteen chapters in the book, and a seventeen-page cyclopedic index. The photographic image, developers, reversal, reduction, intensification, various kinds of printing, and orthochromatism are among the principal subjects dealt with. Mr. Townsend writes lucidly and unaffectedly, and his book therefore is very easily studied and grasped.

CATALOGUES RECEIVED.

Newman & Guardia, Limited, 92, Shaftesbury-avenue, W.C.

The makers of the far-famed "N. & G." hand and tripod cameras send us a useful little blotting-pad, to which a calendar for 1899 is affixed. Two little pamphlets, which describe how the "N. & G." cameras have been found to behave in New Zealand and the Tropics, were also enclosed, together with a list of the Zeiss stereoscopic binoculars, for which Messrs. Newman & Guardia are the agents.

Dobson & Curtis Brothers, Limited, 10, Suffolk-street, Dublin.

In sending us their latest catalogue of photographic mounts, Messrs. Dobson point out that it is compiled on somewhat different lines to the ordinary photographic-mount catalogues. Their chief aim is to list nothing but what they have in stock and ready for delivery. For the convenience of customers they have arranged sample sets.

## News and Notes.

MR. W. F. SLATER, late of 169, Southampton-street, Camberwell, S.E., has secured more commodious premises at 5, Firs-parade, High-road, Lee, S.E.

PHOTOGRAPHIC CLUB.—Wednesday evening, March 15, Beginners' Night. "Elementary Carbon Printing," by Messrs. Elliott & Sons and Mr. T. Skelton.

RENBOLD'S CAMERA SCREW.—This ingenious little contrivance, which we noticed in our issue of February 24, is not yet on the market. It will shortly be placed on sale by a well-known house.

ROYAL PHOTOGRAPHIC SOCIETY.—Ordinary Meeting, Tuesday, March 14, at 12, Hanover-square, at eight p.m. "Theoretical Considerations in Choosing Colours for Three-Colour Printing," by Captain W. de W. Abney, C.B., F.R.S., D.C.L.

MESSRS. PARKIN & FRY, of 31 & 33 Sandstone-road, Old Swan, Liverpool, are the successors to the business of Mr. F. G. Fry, hitherto carried on at that address. Trade enlarging, bromide enlarging, and the manufacture of plates and papers are the firm's specialities.

At the Staffordshire Adjourned Quarter Sessions, on Thursday, 2nd inst., John Henry Williams, aged twenty-two, a photographer, pleaded guilty to obtaining on December 29, 1898, at Stoke, by means of false pretences, the sum of 5s., and also to charges of false pretences at Longton, whereby he obtained 5s. from John Bates and Herbert Shenton. The prisoner, who has been previously convicted, was sentenced to three months' imprisonment with hard labour.

MR. WILFRED EMERY, of 3, Soho-street, W., had the privilege of exhibiting his series of "Folding Ape" cameras at the meeting of the Royal Institution of Great Britain, Albemarle-street, on March 3 inst. The exhibit included the latest additions; a 5x4 with a double swing back, and a 7x5 which only weighs 2½ lbs., and a selection of photographs taken with them. The portability and compactness of these cameras attracted a good deal of attention from the distinguished company.

At the Hammersmith Theatre of Varieties, on Saturday evening last, a series of "animated photographs" was being shown, in the presence of a large audience. The apparatus for working the views was contained in a fireproof room at the back of the stage, and soon after the exhibition commenced something appears to have gone wrong with the films. There was an outburst of flame, followed by an explosion which wrecked the apparatus and put a stop to the show. Andrew Wright, who was working the views, was severely burnt about the face and arms, and appears to have been dragged out of further danger by his colleague, a man named Brock, who escaped any injury to his person. The theatre attendants were immediately on the spot, and in a few minutes the danger of any extension of the flames was over. Meanwhile, the audience had been wondering at the sudden cessation of the views, and were becoming alarmed; but Mr. Hector, the manager, was able to assure them that, although an accident had happened to the apparatus, there was no danger whatever. The injured man was taken to the West London Hospital, and detained. The reason of the accident could not be definitely ascertained; but it was attributed to some fault in the electric current. An official of the London County Council subsequently paid a visit to the theatre, and expressed himself satisfied with the arrangements, and that everything was conducted in accordance with the by-laws of the Council.

## Patent News.

THE following applications for Patents were made between February 20 and February 25, 1899:—

STEREOSCOPIC CARDS.—No. 3790. "Dissolving Pictures for Stereoscopic Cards." T. MITCHELL and M. MITCHELL.

DARK SLIDES.—No. 3939. "Improvements in Photographic Dark Slides and Changing Boxes." A. J. E. HILL and PHOTO, Ltd.

PHOTOGRAPHIC PRINTING.—No. 3978. "Improvements in Apparatus for use in Photographic Printing for Displaying Goods and for other purposes." A. H. BAGNOLD.

PRINTING FRAME.—No. 4015. "The Rapid Photographic Printing Frame." E. C. ARNOTT.

ANIMATED PHOTOGRAPHY.—No. 4024. "Improvements in or relating to Apparatus for Taking and Exhibiting Moving Objects in Motion." A. MILES.

LENSES.—No. 4071. "Improvements in Photographic Lenses." T. R. DALLMEYER.

STEREOSCOPES.—No. 4164. "Improvements in Photo-chromo Stereoscopes; also applicable to Cameras." Complete specification. C. S. LUMLEY, T. K. BARNARD, and F. GOWENLOCK.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
13.....	Bradford Photo. Society .....	The Sunny South. E. B. Fry.
13.....	Camera Club .....	Smoking Concert by Members of the Savage Club.
13.....	Kingston-on-Thames .....	Demonstration: Gum bichromate Process. Paul Armfelt.
13.....	Oxford Camera Club .....	Bromide Enlarging. John H. Gear.
13.....	Richmond .....	Palladium Toning. G. Ardaseer.
14.....	Ashton-under-Lyne.....	Last Day for the Nomination of Officers and Committees.
14.....	Beverley .....	Demonstration with Scholzig's Otto Paper.
14.....	Birmingham Photo. Society ..	Demonstration in Printing and Develop- ing of Gravure Paper. A. C. Baldwin.
14.....	Hackney .....	Naples and Pompeii. R. Beckett.
14.....	Leeds Photo. Society .....	Annual Lantern Exhibition of Members' Work.
14.....	Royal Photographic Society ..	Theoretical Considerations in Choosing Colours for Three-colour Printing. Captain W. de W. Abney, O.B., F.R.S., D.C.L.
14.....	Shropshire .....	Demonstration: Subjects of Interest to Amateur Photographers. J. L. Della Porta.
15.....	Brentford .....	Exhibition of Members' Work, &c.
15.....	Croydon Camera Club .....	Demonstration on the Manipulation of the New Printing Process known as Dekko. E. A. Robins.
15.....	Leeds Camera Club.....	The History of Photography. A. Keighley, F.R.P.S.
15.....	Photographic Club .....	Elementary Carbon Printing. Messrs. Killett & Sons and T. Skelton.
15.....	Southsea .....	R.P.S. Lecture: The Selection of a Suit- able Printing Process.
15.....	Woodford .....	Rambles with the Camera. Messrs. Maibly and Noble.
16.....	Ashton-under-Lyne.....	Annual Meeting.
16.....	Bolton Mutual Photo. Society ..	Italy and its Palaces. Rev. H. S. Alderson.
16.....	Camera Club .....	The Early History of Ornamental Turn- ing. J. W. Woodall, M.A., F.G.S., F.R.G.S.
16.....	Leigh .....	Holidays in the Lake District. W. Hampson.
16.....	Liverpool Amateur .....	Auction of Photographic Goods the Property of Members.
16.....	London and Provincial .....	Lantern Night.
16.....	Plymouth .....	Demonstration. A. C. Baldwin (Paget Prize Plate Company).
16.....	Putney .....	A Holiday in North Wales. John A. Hodges, F.R.P.S.
17.....	Croydon Microscopical .....	British Association Geological Slides. W. Whitaker, F.R.S.
17.....	Kingston-on-Thames .....	A'bars and Omdurman. René Bull.
17.....	West London.....	Demonstration: Platinotype. A. O. Beard.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 2.—Mr. E. H. Bayston in the chair.

Mr. JOHN MCINTOSH, of the North Middlesex Photographic Society, read his Affiliation lecture upon

#### INTENSIFICATION AND REDUCTION.

Under the terms of the loan of the paper, only a short abstract can be given, and, though the lecture was largely dependent upon a numerous series of examples of a comparative nature in conveying an adequate idea of the possibilities of the various methods alluded to, the lecture alone was full of good meat and sound instruction. With few exceptions all the methods of intensification and of reduction extant were considered, and exactly those points in which each excelled over its fellows emphasised. In bringing his lecture to a close, Mr. McIntosh, qualified as he is in matters concerning both intensification and reduction, still was honest enough to point out that, while such expedients were often of extreme value, one should not be encouraged to place too much reliance in what was only a last resource, and urged every photographer to so order himself as to attain success as often as possible in his work in one operation.

Mr. J. S. TRAPE referred to a process of reduction which he thought had not been mentioned in the paper—a process which, though simple and easily used, appeared not to be much practised by photographers. It was made up of 1 drachm of a forty-grain solution of bichromate of potash, and 1 drachm of sulphuric acid, in 4 ounces of water. Supposing a quarter-plate negative be under treatment, 10 drops of this mixture are added to 2 ounces of water, varying the proportions as desired. Reduction proceeds equally right through, and Mr. Trape thought it well worthy of trial. Mr. Howard Farmer's method was good enough with a plate which was still wet, but, where the plate had been allowed to dry, the above was very appropriate.

Mr. EDWIN BANKS reminded the meeting of the black-lead intensifier mechanically applied. The procedure with such a method is to submit the plate to a bath of bichromate and glycerine, afterwards drying the negative in the dark. The back of the plate is then exposed to the light and the black lead applied. It has an advantage over the gum method of intensifying, the coating does not wash away, but adheres to the gelatine very tenaciously.

The CHAIRMAN touched upon a method of improving under-exposed negatives by bleaching them with bichloride of mercury, and copying the bleached positive image in the camera.

Some discussion ensued regarding the precise action of the new reducing salt, persulphate of ammonium. It has been described as, first, a reducing

process, followed by the re-formation of the salt of silver into the metal. In this way the thinner places would be re-formed, whilst the high lights would be reduced, not having time to re-form.

Mr. A. HADDON said that, while there was no doubt of the effect of persulphate in reducing the high lights of negatives while leaving the half-tones and shadows untouched, he thought the theory which was last advanced, mentioned above, was somewhat contradictory.

Mr. W. THOMAS said that, until he had first heard Mr. McIntosh's paper some two or three years ago, he had invariably made up for the defective qualities of negatives, where at all possible, by reproducing them from a positive, and in this way it was surprising what an improvement could be effected.

### PHOTOGRAPHIC CLUB.

MARCH 1.—Mr. Walter D. Welford in the chair.

Mr. SYDNEY KEITH gave an exhibition of lantern pictures from photographs taken on a holiday trip up the Nile, commencing with several bits in the swarming streets of Cairo, round the bazaars, and on, by way of the great pyramids and the Sphinx, through Luxor, Abydos, and Philæ, to Assuan. The wonders of ancient Egypt, disclosed in her ruined temples, many of which have yet to be dug out of the sand drifts of centuries, were perhaps of chief interest amongst the subjects chosen by Mr. Keith for his camera, including, as they did, hieroglyphic writings of great antiquity in an astonishing state of preservation. A short chat followed upon the history of Egypt, very fruitful of conjectures upon the colossal undertakings successfully accomplished and the means adopted, and a hearty vote of thanks brought the meeting to a close.

### Croydon Camera Club.—

THE KENTISH PALACE HOME OF THE SIDNEYS.

The main subject of the Croydon Camera Club's Fortieth Public Lantern Show, held on Wednesday, March 1, at the Small Public Hall, was Penshurst Place, that noble and notable pile of buildings which stands in its historic and picturesque park hard by the confluence of the rivers Eden and Medway. The slides illustrating the above were taken on June 28 last, when, by special invitation of Lord de Lisle and Dudley, a large party of members of the Club were given the run of the palace, park, and pleasures in order to photograph what they wished. The slides were described by the PRESIDENT (Mr. Hector Maclean), who began by tersely sketched particulars respecting the building of the palace and some of the notable personages who have dwelt in it. The subjects were made more interesting by the running comments of the lecturer. Many of the slides came in for hearty applause. *Queen Elizabeth's Room*, showing Queen Victoria's coronation stool (Underhill), a fine slide of the *Tapestry Room* (Chadwick Taylor), and the *Armour Corridor* (Watson), are but a few of the seventy views which received marked approval. Besides this rich feast of antiquarian art and nature, the audience was given a peep at Broomhill and its many marvels. That all the features of this remarkable building were not fully illustrated was, the President explained, due to the great affability, the attractive conversation, and the engrossing experiments and demonstrations with which the owner of Broomhill (Sir David Salomons) fascinated the members when they made their memorable visit, so that, although they were loaded with cameras and surrounded by attractive subject-matter, they could not tear themselves away from Sir David and the contents of his mansion of many marvels. Councillor Noakes showed his photographic records made in the land of Burns during the Photographic Convention, including the cottage in which the greatest of all Scotch poets was born. A Highlander entertaining passengers on a Clyde steamer was described as playing the only really musical instrument ever invented, which satirical euphemism for the bagpipes raised a hearty laugh.

Liverpool Amateur Photographic Association.—March 2, Mr. Paul Lange (President) in the chair.—Mr. JOSEPH APPLEBY gave a demonstration on

#### CARBON.

Mr. Appleby demonstrated the working of carbon printing, a process which has been very much revived during late years, and which is the principal process used by modern photographers; in fact, platinotype and carbon are the two pre-eminent processes used by first-class workers. He demonstrated the sensitising, developing, and transferring of the picture, and left a number of specimens illustrating the various colours to be obtained by the carbon process, which will be on view in the rooms for the use of members during the next few days.

Newcastle-on-Tyne and Northern Counties Photographic Association.—At the last meeting of this Association Messrs. W. S. CORDER and GILBERT SPENCE gave a demonstration of

#### PHOTOGRAVURE.

The demonstrators went through the whole process in a most practical manner. In laying down the resist on the copper, which they grained in the presence of the audience, Messrs. Corder and Spence stated that they made a point of thoroughly boiling the water in which the tissue was soaked preparatory to squeezeing, finding by doing so a greater freedom from air bells, which otherwise were liable to form in the minute interstices between the bitumen grain. At the moment of laying down the tissue they also breathed upon the grained copper which also was a help to the same end. After the development and drying of the resist the demonstrators proceeded to etch. At this point they stated that there were three methods of using the perchloride of iron solution—(1) to keep the solution in separate bottles at different strengths, using these in succession on the plate; (2) to commence with a strong solution and gradually weaken it by adding water as the etching proceeded; and (3) to work with a solution at one strength all through, 38° R., the latter being the method recommended by that eminent photogravurist Mr. Huson, which method required that the transparency should be particularly perfect in all its gradations. The method selected by the demonstrators was that of commencing with four ounces of a solution at about

48° B. on a half-plate-sized piece of copper and diluting this with two drachms of water from time to time until about 36° B. was reached. This worked well, two very fine plates resulting. The demonstrators then proceeded to show the method of inking up the plate and finally pulled some very passable prints despite the fact they had only a whole-plate rolling press with blotting-paper as a blanket to work with. The demonstration went through without a hitch, not a "devil" putting in its appearance to stop the facility with which the demonstrators put the plate through the various stages.

**Plymouth Photographic Society.**—March 3, The President in the chair. —Mr. W. J. BELTON, as the representative of Messrs. John J. Griffin & Sons, gave a very interesting lecture and demonstration on

#### VELOX,

and the large number of members present gleaned many bits of information concerning the paper and the chemicals used in the working of it. Mr. Belton said that the paper was a bromo-chloride with very little gelatine, and that by making a suitable selection from either of the two grades, ordinary and special, a good print could be obtained from any kind of negative. The special series was about twenty-five per cent. more rapid than the other. With Velox, exposure was the most important point, and the right amount could only be found by trial (strips across the negative was an economical way). The developer as put up either in packets or tubes, was the same in each case, only the tubes cost money and were charged extra for. Make up the quantity in a four-ounce bottle, and so do without a lot of bottled air, three or four drops of ten per cent. bromide added would be sufficient. The developing was best done with a camel's-hair brush, the kind known as a gilder's mop being the most suitable, but for very large prints make a brush by drawing a large tuft of cotton-wool by means of string through a piece of glass tube. In the printed instructions acetic acid was mentioned and an error is likely to be made, owing to the quantity being given for the American strength of the acid; but, if to 1 drachm of the P.B. article as sold in England 7 drachms of water be added, it will then be about right to use according to the printed formulae given.

**Glasgow Photographic Society.**—March 2, Mr. William Lang, F.C.S. (Vice-President) in the chair.—The meeting was held as a Ladies' Night, and there was a large attendance. Mr. A. LINDSAY MILLER gave a lecture on

#### RAMBLES WITH A CAMERA,

illustrated by about 120 slides made by him from views taken chiefly in Lanarkshire and the Vale of Clyde, the beauty and excellence of which slides should give a fillip to hand-camera work in the district. About thirty kinematographic films, including a number taken during the Egyptian War, were lent and exhibited by Messrs. Rae Brothers, and contributed largely towards making the meeting a success. The Convention film taken by Mr. E. P. Prestwich at the recent meeting held at Glasgow, and which contains exceedingly good and characteristic moving portraits of many of the leaders in photography, was called for a second time and had to be repeated. The meeting was brought to a close by votes of thanks to Mr. Miller, Messrs. Rae Brothers, and to Mr. Prestwich, who had lent his Convention film to the Association for exhibition.

#### FORTHCOMING EXHIBITIONS.

1899.	
March 10, 11 .....	South London. Hon. Secretary, A. E. Allen, 27, Princes-square, Kennington Cross, S.E.
" 14, 15 .....	G.E.R. Mechanics' Institution (Photographic Section), Stratford, E. Hon. Secretary, H. W. C. Drury, St. Oswald's, Downs-road, Clapton, N.E.
" 15, 16 .....	Brentford.
" 20-May 13 ...	National Trades and Industrial Exhibition, Bingley Hall, Birmingham. Manager, Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.
April 3, 4 .....	Beverley. T. J. Morley, Toll Gavel, Beverley.
" 12, 13 .....	Plymouth Photographic Society. Hon. Secretary, W. H. Harris, 91, Cobourg-street, Plymouth.

### Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### THE FOCAL LENGTH OF A LENS.

To the EDITORS.

GENTLEMEN,—Both "J. F. T." and I have a desire in common to place before your readers the simplest and, at the same time, an accurate method of determining the focal length of an ordinary positive lens without the use of elaborate apparatus. I therefore trespass further on your space for the purpose of elucidation and not controversy.

To measure the distance of the front focal plane from the hood of the lens, when the latter is reversed in the camera and focussed for parallel rays, is an easy matter practically. Temporarily remove the ground glass from the frame of the focussing screen and replace it by one half the size (consider the glass cut in two and one half removed). A rule can now readily be placed inside the camera in contact with the rim of the hood; the distance between hood and screen can then be read off on the rule at

the edge of the ground surface of the glass. A slight error, if it exists, becomes negligible because the final measurement to the hood is made from the object, some distance off.

When the lens is next placed in its ordinary position in the camera, the *locus* only of the back focal plane (position for parallel rays) is required, and no measurement is necessary to determine it.

Measurements are then made of (1) the distance between a near object and the hood of the lens, less the distance between the hood and the front focal plane already found, and (2) the displacement of the focussing screen from the back focal plane, which is necessary to bring the image of the object into sharp focus.

Then the focal length =  $\sqrt{(1) \times (2)}$ .

Concurring with "J. F. T." in the fact that it is difficult to carry out measurements from the "principal" or "nodal" points of a lens, even when they are contained in the mounting of the lens itself, led me to substitute measurements from the focal points or planes, as they are easily arrived at and convenient. By this method the separation of the nodal points need not trouble the photographer, to whom they would be a little puzzling if they were beyond the mounting of the lens, or perhaps crossed.

Allow me to take this opportunity of thanking "Free Lance" for his very civil defence in another matter. I entered a protest on the day of publication. "Free Lance" will, of course, see that "focus" should read "focal length," "negative" should read "positive," and "any object" should read "an object at a given distance."

In thanking you, Gentlemen, for your appreciative reference to the Traill-Taylor lecture, permit me to say that I only had a limited number of these special "pulls" printed, but that any one of your readers who may apply for a copy at 25, Newman-street, is most welcome to it while any are left.—I am, yours, &c.,

THOMAS R. DALLMEYER.

Boscombe, March 3, 1899.

#### ACETYLENE EXPLOSIONS.

To the EDITORS.

GENTLEMEN,—We have seen in your issue of February 10 an account of an acetylene explosion at Chesterfield which has evidently been derived from the same badly informed source as the paragraphs which were published in the papers all over the country.

The explosion is described as an awful and remarkable one, and that two people were injured and several had narrow escapes. In order to investigate the truth of the matter, we sent a representative to Chesterfield to visit Messrs. C. J. Saunders & Co.'s works, where the explosion occurred. After making inquiries, he was informed that the explosion happened as follows: A light was applied to the gas at the outlet, and it burned for a few minutes before the explosion took place, the cause of which was that the air had not all been exhausted from the holder before the acetylene gas was made. So far from any one being hurt, Mr. J. Saunders, Managing Director, wrote to the *Derbyshire Times* on February 11, that the only injuries sustained by any one were very slight, and caused by a small part of the wooden roof falling on to Mr. Richmond's head. You will easily grant that the violent character of the accident has been exaggerated when we say that Mr. Richmond was standing within two feet of the holder, and did not feel the slightest atmospheric disturbance; and the works' Manager, who was standing about ten feet away, did not move his position until the gas-holder had dropped on to the ground.

We beg to submit to you that, so far, there have only been three acetylene explosions in England which have been reported in the Press, and two were caused by the use of badly constructed generators by essentially ignorant people. Further, the number of accidents from acetylene altogether have been very small in proportion to the extent of its use; and the great majority of those that have occurred have taken place on the Continent, and have been caused either by risky scientific experiments or the compression of gas into a liquid form, which latter is strictly prohibited in England. We consider that such paragraphs as the one to which we have taken exception do a considerable amount of temporary mischief to a large and growing industry. Acetylene is known by all experts to be perfectly safe to handle.

We trust you will insert this letter, and are, yours, &c.,

THE THORNTON-SCARTH AUTOMATIC LIGHTING SYNDICATE, LTD.  
Artillery-street, Small Heath, Birmingham, February 27, 1899.

#### PYRO AS A LANTERN-SLIDE DEVELOPER.

To the EDITORS.

GENTLEMEN,—In your issue of the 3rd inst. there is a letter from Mr. Louis Meldon, of Dublin, in which he refers to an article written by me re the development of lantern slides.

In taking notice of this, I would merely remark that I have never experienced the unequal development which Mr. Meldon refers to, and I can confidently say that, provided freshly coated plates be used and the formulae which I gave be closely adhered to, he will not be troubled with any of the defects he refers to. The use of soda with pyro in the development of lantern slides is quite a common procedure.—I am, yours, &c.,

T. N. ARMSTRONG.

Viewfield House, Shettleston, March 6, 1899.

## CATALOGUES WANTED.

To the Editors.

GENTLEMEN.—I enclose notice of last meeting of our Society, which may interest your readers.

You kindly inserted a notice of the formation of the Society in October last. I must say I have been surprised at the want of enterprise shown by advertisers, as, although said notice was inserted in three journals, only three or four catalogues or lists were received by me. One would have thought that the formation of a new Society with about eighty members would have caused a flood of lists, &c., to be sent to its Secretary.—I am, yours, &c.,

S. STEWART, Secretary.

Kirkcaldy Photographic Society, 2 Salisbury-street, February 26, 1899.

[Notices of the formation of societies are not primarily inserted in our columns for the purpose of attracting catalogues, but rather as items of news. However, we have no doubt that the prominence here given to Mr. Stewart's wish to be favoured with trade literature will result in his receipt of enough to satisfy his requirements.—Eds.]

## NELSON'S GELATINES.

To the Editors.

GENTLEMEN.—In your issue of March 3, 1899, we notice, under Answers to Correspondents, the following:—

Gelatine, Chondrin, &c. A. Baker says: "I see by your JOURNAL of September 23, 1898, you believe there is one firm that makes photo-emulsion gelatine in England. Will you kindly give me the address? I think my failures are due to bad gelatine." In your answer you say, We do not know of any firm that supplies gelatine emulsion.

We remember reading, with great interest, an article by C. T. Sutton, on "Gelatine for Emulsion Work," in your issue of September 23, 1898.

It is unnecessary for us to point out to you that a photo-emulsion gelatine and a gelatine emulsion are vastly different things, but at the same time take this opportunity to inform you that for many years we have made photographic gelatines for emulsions. Of late years we have spared neither time nor money in endeavouring to provide a gelatine suitable to all the large plate-makers in this country; but, owing to the variations of their formulæ and the peculiarities of gelatine, we have so far not been quite as successful as we should wish. We now, however, trust in a very short space of time to be able to put on the market a gelatine which will give satisfaction to the largest of the plate-makers in this country.

We venture to enclose you a list of our present make of photographic gelatines, and also a little booklet, *Round about Warwick*, which will give you details of a somewhat extensive and interesting manufactory.—We are, yours, &c.,

GEORGE NELSON, DALE, &amp; CO., LIMITED.

FREDERICK W. NELSON, Secretary.

14, Doughty-hill, London, E.C., March 7, 1899.

[Owing to an oversight, the question and answer to which Messrs. Nelson, Dale, & Co. kindly direct our attention were not so clearly given in print as they should have been. The querist wished to know if gelatine emulsion was obtainable commercially in this country. So far as we are aware, it is not. We shall refer to the enclosures of Messrs. Nelson's letter in our next.—Eds.]

## SPECIMENS.

To the Editors.

GENTLEMEN.—I enclose herewith an advertisement (Wanted, a few dozen attractive cabinet specimens for show-case, toned, unmounted. Price.—H 21, 24 Wellington-street, Strand, London) cut from this last week's JOURNAL, and am wondering in my own mind if you would think me rude or interfering if I was to ask if you couldn't refuse to insert such advertisements. I would ask this for two reasons: First. In the interests of the trade. Photographers as a body are men of honour, and would be ashamed to show as specimens (with a view of obtaining business) work not their own.

Second. In the interest of the public, is it quite right that our leading photographic paper should be the means of deceiving the patrons of photography?

I may, of course, be wrong in my ideas as to what the specimens are wanted for; but I fear the wording of the advertisement leaves little doubt as to the uses they are to be put to.

Trusting you will pardon my apparent presumption in thus writing you,—I am, yours, &c.,

HARRY FRENCH.

P.S.—You are quite at liberty to publish this if you think fit.

[We do not at all agree with our correspondent that the traffic in specimen photographs necessarily calls for the severe degree of discouragement he appears to advocate. It is easily conceivable that a man just starting in business may have nothing of his own production to place in his show-cases for the purpose of attracting the attention of passers-by, and, in such circumstances, if he can procure specimen photographs to serve his object, he, in our opinion, is justified in doing so. Many photographers' show-cases in the

country probably contain enlargements, coloured prints, and so forth, which are not their own work—they are supplied by the trade houses. These, as well as purchased specimens, are placed on view for the purpose of informing the public that the photographer undertakes work of a similar kind. On the other hand, where specimens are used as instruments of deceit or fraud, the highest reprobation is obviously called for.—Eds.]

## RE BIRMINGHAM EXHIBITION, STUDY OF A CHILD'S HEAD, NO. 103.

To the Editors.

GENTLEMEN.—On looking over this week's issue of your JOURNAL, I notice I am accused of copying Mr. Harold Baker's *Geoffrey*. I may state I made my picture when the child was some two years old, he is now six years of age. I had never seen Mr. Baker's picture, or even heard of it, if it was in existence. It was framed in London, and my only instruction was to put it in a crate. Therefore I cannot see how I can be accused of copying a picture I had never seen.

I feel sure you will make this matter all right as it is hardly fair to me.—I am, yours, &c.

ALEX GEEKIE.

Abbotsville, Coupar Angus, N.B., March 4, 1899.

[Our remark was that "Mr. Geekie's *Study of a Child's Head* looks uncommonly like one of Mr. Harold Baker's, *Geoffrey*." The resemblance struck others in the room besides ourselves, including Mr. Baker. We did not impute copying, and therefore have nothing to put right; all the same, we are sorry if in noting an obvious resemblance our remark should have created a false impression on Mr. Geekie's mind.—Eds.]

## THE R.P.S. AND PROFESSIONAL PHOTOGRAPHERS.

To the Editors.

GENTLEMEN.—You have kept us well informed of the aspirations of the chemists and druggists and their attempts to promote legislation for their own interests through the Pharmaceutical Society. The average chemist and druggist and the average professional photographer seem to have many ideas in common, and after the chemist and druggist there is probably no one in business who has such narrow-minded views of business as the photographer. The chemist and druggist is always loudly proclaiming the danger to the public there is in—well, it amounts to this—not giving him a complete monopoly. Your correspondent, "Pro bono Publico," on behalf of the photographers, treats us to the same familiar wail. It is, Protect the public or protect us, as you please to look at it.

We can all recognise the necessity for some restrictions on the sale of poisons, of explosives, and of other articles that might cause harm by indiscriminate circulation, and there seems no practical way of controlling the sale of these things except by restricting it to certain individuals who, in return for the advantages of possessing a monopoly, have to undertake some kind of responsibility; but the worst example of photography ever perpetrated can hardly be considered a dangerous article to any one. Your correspondent says, "It is disgraceful and a fraud on the public that any one can be free to rush into business" (as a photographer) "who has no experience or knowledge of the work." But is not this equally true of the butcher, the baker, the candle-stick maker, to say nothing of the tinker, the tailor, the cobbler, the nailer, and is it true at all? The one cabinet and six *cartes* for 3s. 6d. man may turn out atrocious photographs, but he must satisfy the class he caters for, or his customers would not come again, and, more important to him still, his customers' friends would not come to him—a photographer's is not a chance trade.

From the narrow point of view your correspondent looks upon these matters, they may be trusted to right themselves. The man who gives the good value for the money, as the public consider, if his methods are fairly businesslike, will always succeed.

Your correspondent asserts "that a man may be F. or M.R.P.S., and yet not qualified to conduct a business as a photographer." Granted; but, taking all the respectable photographers in the kingdom, and "respectable" I will define as those whom "Pro bono Publico" would think worthy of being included in the Ring, how many are qualified to conduct their business on the same business lines that a draper, a tailor, or a bootmaker, would find necessary? It is no uncommon thing for a photographer to take ten days to deliver a proof, and months to deliver a dozen photographs, the light is so bad this time of the year, &c. The photographer who wails and weeps over want of work is almost always far behindhand with the work he has. Goodness knows what would happen if he had as much to do as he thinks he deserves.

With regard to the R.P.S. "and the profession." It is clear that the Society, from its constitution cannot do much to butter the bread of the ordinary photographer, the portraitist whose bread depends upon turning out so many portraits at so much per dozen. The Society is instituted for the advancement of photography, and only incidentally for the advancement of photographers. The majority of its members, the country members in particular, gain little directly, but are content to

subscribe to it for the sake of the work it does in advancing photography. The ordinary photographer is not, as a rule, a supporter of the Society, or of any photographic society, and, as a rule, he hates photographic societies. At photographic society meetings they talk openly of things he wants to keep secret. He does not want to tell what he knows, and he does not want to learn anything. His interest in the advancement of photography is only an *l. s. d.* one.

Professional photographers cannot even combine for their own interests. Where is the Photographers' Benevolent Association now? That was an institution for the benefit of professional photographers, and, with a reasonable amount of support from the profession, would have become a credit to it and a valuable aid for the sick and wounded. For years it lingered on, almost entirely supported and administered by amateurs and dealers, for the benefit of the professional photographer, who would not help himself, but was quite content to allow outsiders to pay for him and work for him. Where is the National Association of Professional Photographers? That came to grief, after a very brief existence, because its members did not know what they wanted, and, if they had done so, would have had no idea of how to set to work to get it. I am almost ashamed to sign myself

A PROFESSIONAL PHOTOGRAPHER.

### OPERATORS AND AGREEMENTS.

To the Editors.

GENTLEMEN,—About eleven months ago I was offered an engagement at a photographer's at Weymouth as managing operator and artist at a salary of 3*l.* 10*s.* per week, with the understanding that, after a month's trial, if my work proved satisfactory, I was to have a two or three years' agreement. I gave every satisfaction, and the agreement was to be drawn up. Upon the strength of this promise I took a house yearly, and brought my wife and family. However, from that time until about three weeks ago the agreement was not forthcoming, various excuses being given as the reason. Well, about three weeks ago (about the slackest part of the year) an agreement was handed to me, with the intimation that I could either sign it or leave. As the so-called agreement was not only not equitable, but thoroughly unfair, I declined to sign it.

I enclose a copy of the document, which I trust you will see your way to publish as a warning to assistants.—I am, yours, &c.,  
Weymouth, February 28, 1899.

OPERATOR.

"An agreement, made — day of —, one thousand eight hundred and nine-nine, between —, of Weymouth, in the county of Dorset, Photographer, of the one part, and —, of Birmingham, Photographic Artist, of the other part.

"Whereas the said — has agreed to take the said — into his service as his chief photographic operator, retoucher, artist in black-and-white and colours, in his business at Weymouth aforesaid, at the weekly salary of three pounds and seven shillings, and, in consideration of such agreement and of the salary paid to the said — mentioned, he, the said —, has agreed to enter into the engagement hereinafter contained.

"Now it is hereby agreed as follows:—

"1. That the said — will pay the said — for his services the weekly salary of three pounds and seven shillings.

"2. That the said — will conduct himself properly and faithfully during the said term, and will daily to the best of his ability execute the duties of photographic operator, &c., for the said —.

"3. That the said — will not during the engagement created under this agreement or at any time thereafter, without the written consent of the said —, commence or carry on, either alone or with others in partnership, the business of a photographer in Weymouth or within a radius of thirty miles from the town of Weymouth, nor engage himself to any other photographer within a like radius, either as operator, retoucher, or otherwise, and as often as he shall do so he will pay to the said — the sum of two pounds for every week during which he shall commit such breach, and such amount shall be recoverable from the said — as ascertained liquidated damages.

"4. If the said — shall not carry out his duties to the satisfaction of the said —, or shall not in all things observe, perform, and fulfil the conditions of this agreement, the said — shall be entitled to discharge the said — upon giving him two weeks' notice to leave his employ, and, upon such notice being given, the said — shall leave such employ accordingly at the expiration of such notice; but he shall continue to be bound under clause 3 of this agreement.

"As witness the hands," &c.

### THE LEEDS CAMERA CLUB AND THE YORKSHIRE PHOTOGRAPHIC UNION.

To the Editors.

GENTLEMEN,—I have read with some considerable amount of amusement Mr. Warren's letter in this week's issue, and I am bound to acknowledge that, as a literary effort, it would be difficult to equal it.

To subject this epistle to analysis is to spoil its beauty, divest it of its verbiage and scarcely a tissue of solid argument remains. My opponent's references to ancient history and mythology impart a distinctly literary flavour to what might otherwise have been a prosaic and commonplace discussion. My friend, Mr. Warren, will pardon me for saying that his game of ridiculing an opponent, instead of tackling his arguments, is as old as the hills, and it is almost impossible to score with it. Mr. Warren's reference to Alexander is a little *mal-a-propos*. That distinguished gentleman, if history libelleth him not, was invariably the

aggressor, while, on the contrary, the present writer confines himself to taking the defensive attitude.

I will take Mr. Warren's points in detail. He reaffirms his atomic theory as applied to individuals and to photographic societies. Shades of Dalton, Huxley, and Tyndall! A repellent and conflicting atom, with a coherence and attraction for other and similar atoms, is a startling phenomenon. I have already proved this theory of atoms, as applied to photographic societies, to be, as the logicians say, *argumentum ad absurdum*. To make the analogy perfect, the photographic atom should lack the forces of cohesion, affinity, and attraction, all of which the photographic unit now possesses in a remarkable degree. I must press this point home, for this is the bone of contention between Mr. Warren and myself. My opponent says that societies cannot federate, because their interests are so conflicting, and then he builds up an astonishing theory of molecular force, which is not analogous or true to facts. Again, I repeat, there must be some common ground of agreement, affinity (to use the chemical term), or there would be no combination of units in the shape of societies.

I would venture to remind Mr. Warren of an old Yorkshire story, which, so far as I remember, is as follows: An old countryman, for some trivial offence against the laws, was placed in the village stocks. A small group of his old cronies gathered round to condole with him, and generally discuss the situation. One of them, evidently of a legal turn of mind, turns to the culprit, and gravely informs him that the powers that be cannot place him in the stocks for the offence with which he had been charged. The victim savagely retorts, "Can't tha? but tha her done, and awm here na." Now for the application to this little story: *conflicting atoms*, i.e., photographic societies, we are told, cannot be federated; but they are being amalgamated, fifteen already, and more to follow.

I have already stated that I admit the right of the Leeds Camera Club to do the best it can for its own interests, but I do not admit the right of its President to attack the Union without first trying to understand the details of its constitution. I have also further stated that the eight Bradford gentlemen have ceased to exist as a provisional Committee, and that the three delegates who have been elected constitute all the representation to which that Club is entitled.

Mr. Warren accuses the provisional Committee of having attempted, in a *hole-and-corner* fashion, to appoint him as Treasurer of the scheme. I have already denied, in a letter to Mr. Warren some weeks ago, the truth of this accusation. Neither myself nor my Committee had anything to do with that election, and I protested at the meeting that the appointment was a blunder, and that Mr. Warren would not accept the position. I will take this matter a little further. Mr. Warren says this *hole-and-corner* appointment was not made at the meeting referred to. Now, Sir, your reporter was present, and the *Photographic News* contained the announcement that Mr. Warren was appointed Treasurer *pro tem*. Where did that reporter get his information?

In conclusion, let me say that I am quite prepared to meet any attacks which may be made on the scheme as an honest attempt to deal with the problem, but cannot be expected to prove the possibility or otherwise of performing miracles. The Yorkshire Union is entitled to expect from Yorkshire societies, until the scheme has had a fair trial, an attitude of benevolent neutrality. Shakespeare says, "'Tis not in mortals to command success," but the delegates of the Union will do more, they'll deserve it.—I am, yours, &c.,  
EZRA CLOUGH.

13, Chesham-street, Bradford.

NORMANDY.

To the Editors.

GENTLEMEN,—I note the request of "Rambler," as to Normandy, and, if you like to put him into communication with me, I can perhaps help him, having made three autumn holidays there with camera, and visited some twenty towns in Northern France and Normandy, though but little on the coast, except Dieppe and Fécamp. I found the coast places rather uninteresting, and prefer the picturesque qualities of the older towns, as Caen, Rouen, Caudebec, and Lisieux.

It is "too large an order" to ventilate this matter in the *JOURNAL*, but "Rambler" can put any questions he likes to me and I will answer them as well as I can.

As to figure studies, there may be plenty in the fishing population, but there is also no lack of them among the "antiquities" of the market stalls and fish markets of the interior towns.—I am, yours, &c.,  
GEORGE BANKART.

My work was all done on plates 11×9—about 180 negatives in the three holidays.  
West Walk, Leicester, March 4, 1899.

### AN ASSISTANT'S DILEMMA.

To the Editors.

GENTLEMEN,—Re the above question, my experience is very much the same as "F. S.'s." As a rule, I answer four to six advertisements each week, and the usual thing is no replies; and, if so, it is no good, and many a time specimens even never returned. I should like to know how I can get at the advertiser when there is only a number to the advertisement. I answered an advertisement the other week which ran something

like this: "Wanted, good operator and retoucher, &c., to manage branch; married. Apply, references, specimens," &c. I was lucky or otherwise to receive a reply from them, and the magnificent salary of 11. a week was offered. I should like to know how a married man is going to manage on this, as it is simply ridiculous. It certainly shows that the country is over-crowded with photographers if a firm expects to get a man for this figure.

I am considered a first-class operator and retoucher, &c., so that it is not from lack of ability I don't get a berth.  
Trusting you will insert this,—I am, yours, &c., J. A. H.

#### To the Editors.

GENTLEMEN.—In reference to the above, "W." and "F. S." are certainly not the only assistants who find it difficult to get into a good situation. Good situations are scarce, also good assistants. I should be pleased to hear the definition of a first-class assistant. Having been an assistant for over ten years, I can only conceive a good assistant to be of unsurpassable beauty of physique and culture, also a scientist and artist of exceptional ability, and to receive the handsome remuneration of 30s. Not being up to that standard, I must be satisfied with 25s. for a permanency of eight months. This being the idea of a photographic professional who has the honour of M.R.P.S. attached to his name, and who thinks that a reference of this description,—

"Mr. — has been in my employ, and can recommend him as an all-round man. He is very attentive to his duty.—Yours, &c., M.R.P.S.—"

would prove beneficial to his late assistant, who has done all his retouching and part of his operating. This is merely the truth, and my opinion is that, after a few more assistants are served in this manner, they will make a desperate attempt to form a union for the purpose of obtaining more just treatment.—I am, yours, &c., A. A.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

#### PHOTOGRAPHS REGISTERED:—

A. G. Field, 5, Alston-place, Maidstone.—Photograph of Karl Marx.

H. Colebrook, 5, Grosvenor-terrace, Station road, Sidcup, Kent.—Photograph of steam-boat "Oceans."

J. Landon, 134, Queen's-road, Watford, Herts.—Photograph of Mr. and Mrs. Crawley and family, who were poisoned at Watford on February 10, 1899.

F. T. Blackburn, 2, Station-road, Budleigh Salterton.—Three photographs:—1. Photograph of hailstones grouped together in tray, the hailstones weighing half an ounce each. 2. Photograph of the Rev. Robert Charles Price, sitting with a book open on table. 3. Photograph of Miss Isabella Warrington, with cap and apron on (bust).

RECEIVED.—W. BARRY; AJAX; S. TALLON; G. W. YOUNG; H. BARRETT. These and others in our next.

"AN ASSISTANT'S DILEMMA."—Will "W." send us his address? A letter awaits him.

THOS. STEVEN.—You would be liable to an action for infringement if the engraving is copyright.

H. M. WARD (Leicester).—Many thanks for the cutting, which had reached us from several other sources. The paper in question is acquiring an unenviable reputation for printing the most ridiculous rubbish about photography.

COLLODION PROCESS.—C. BANCRO. The ferrous-oxalate developer as used for gelatine plates is of no use with wet-collodion plates. The proto-sulphate of iron (acidified), as given in the manuals, must be used. The two processes are widely different, which you do not seem to realise.

DESIROUS.—A very good photograph indeed, but the subject is so commonplace and unpicturesque that you would hardly be justified in sending it to an open exhibition. Do you ever visit the exhibitions? Unless you do so, you are working in the dark if you aspire to success in open competitions.

DAMAGE TO STUDIO.—S. S. says: "During the late hurricanes several large squares of glass were broken in the studio. Who is to make them good, the landlord or me? I have the place on a fourteen years' lease, and have to do the repairs; but I am told this is not fair wear and tear, but the 'act of God,' and that the landlord must do the needful. That he denies."—As you hold the premises on a repairing lease, you will have to make the damage good, if done at all.

CAMERON.—You omitted to sign your name and address. However, in reply: 1. A denser negative is required in the first-named process. No difference in the lighting is required. 2. Theoretically all lenses of equal aperture are of equal rapidity; focal length has practically nothing to do with it. 3. The glasses you name give a slight but scarcely appreciable increase of rapidity. 4. See reply to No. 2. 5. Yes; because the portrait lens works at the larger aperture. You evidently require to consult an elementary work on photographic optics.

COPYRIGHT.—W. RHYS JONES asks: "Would you kindly inform me as to whether I would be breaking the law of copyright in selling an enlarged copy of photograph taken twenty-two years ago."—In reply: If the copyright of the original is in force, you would render yourself liable to action for infringement.

M—PHENYLENDIAMINE.—PHOTOGRAPHER says: "Would you kindly let me know where I could be likely to obtain M—phenylenediamine, as recommended for new platinum toning bath, in JOURNAL of February 17?"—In reply: Messrs. Zimmermann, St. Mary-at-Hill, or Messrs. Fuerst Brothers, might procure it for you.

AGREEMENT FOR SERVICES.—ASSISTANT. If you are entering into an agreement for a year's services, have the agreement in writing, and stamped, otherwise you may find yourself in the same predicament you say your predecessor was at the end of the season, and as many others have done with verbal agreements—with some employers.

A. L. (Paris).—We presume you refer to a photograph to be taken in London. —In reply: 1. No permission is needed for street photography in England. 2. There is no liability for damages. 3. No. 4. Neither is liable. 5. The architect cannot object. 6 and 7. No, he cannot sue him. It all amounts to this, that in England street photography is absolutely free.

H. J. B.—A search at the Trade Mark (Patent) Office would be necessary to find out whether "Celloidene" is a registered word or not. "Celloidin," however, is a word frequently used, especially on the Continent, to denote collodio-chloride paper, so that you would be getting uncommonly near an already recognised term. We should advise you to choose some other word.

DEVELOPING MARKS.—BEGINNER. The wavy or mottled markings are caused by the plate not being rocked while being developed. Although the negative may require a long time in developing, the developer should be kept in motion the while, though more at the first part of the time than is necessary at the later stage of the development; but it should not be allowed at any period to be at rest for long. There is no doubt as to the cause of the markings.

SPOTS ON PRINTS.—F. DOWDALL says: "Will you inform me the cause of spots on enclosed print, there are half a dozen with similar marks out of a large batch; is it the water, or do you think it might possibly be dust settling on them while spread out to dry?"—The spots may be due to either of the suggested causes, or several others; but it is impossible for us, by merely looking at a print, to say the precise one. See article on page 83 of our issue of February 10.

A COMBINED BATH.—PYRO says: "Re 'A. J. B.'s' inquiry in your valuable JOURNAL of last Friday for a combined toning and fixing bath, I venture to offer the following formula, which I have used with every success: 6 ounces of hyposulphite of soda, 6 drachms of sulphocyanide of ammonia, 32 ounces of water, 14 grains of gold. This bath to be made twelve hours before using, and tones from red to blue may be obtained easily with it. It is advisable not to throw away the old bath, but use half old bath and half new. This bath should tone between six and seven sheets of paper."

DEAD BLACK STAIN.—J. W. says: "I have searched through back numbers of JOURNAL and ALMANACS for a great many years, and can't find a reliable stain for brass for the purpose of reblacking lens stops, &c. The much-repeated copper nit. not being successful in my hands, can you say what is used by opticians for giving that beautiful dead black on the inside of lens mounts (a stain, not ivory black and shellac), black bands around lenses, and such work, as I am remounting an old lens with which I have done much work for about twenty years?"—The receipt given on page 972 of the ALMANAC has never failed in our hands. Another method of blacking brass is to thoroughly clean the metal, warm it, and then dip it in a weak solution of bichromate of platinum. Probably your failure has been due to the metal not being perfectly clean.

GLASS POSITIVES AND FERROTYPES.—OLD LITHO writes: "I have bought an old camera and lens of a shop-mate, and I wish to try my hand at photographing, only for amusement, and I wish to ask, would you give me in your correspondence a receipt for making a silver bath, a developer, and fixer, for glass positives up to date, and will same do for ferrotypes; if not, will you oblige? I have not come across yet, in your ALMANAC, anything to assist me, or, if you know of any publication that would assist me, I should be thankful?"—Formulae for sensitising bath, developer, and fixing solution are given on pp. 1056, 1057 of the ALMANAC. The solutions that are good for glass positives will also do for ferrotypes. Any of the old manuals of photography of fifteen or twenty years ago, Hughes for example, give the manipulatory details of the process. If we mistake not, Fallowfields publish a pamphlet on the ferrotype process.

AMMONIO-CITRATE OF IRON.—J. G. WILLIAMS says: "Enclosed was made from formula as follows: \* A. Ammonio-citrate of iron, 35 parts; tartaric acid, 4 parts; distilled water, 200 parts. B. Gelatine, 6 parts; distilled water, 100 parts. C. Silver nitrate, 10 parts; distilled water, 100 parts. Above mixed and applied with brush, as directed in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1899, p. 937. \* Formula given says green ammonio-citrate of iron, but local chemist did not know this, and supplied me with the ordinary brown-scale crystals. Is this an error? I should be glad if you could advise me as to probable cause of the brown stain left in the paper, which, I presume, ought to have cleared out."—We quoted the two formulae as given by the authors of the two methods. Probably the paper itself is at fault, having a reducing action on the silver. Try the formula with the ammonio-citrate of iron you have on a better paper, that of the post card enclosed is of the commonest description and very different from that of the cards issued by the Post Office. Messrs. Marion & Co. supply material for the purpose.

## EX CATHEDRA.

THE Invitation Section of British Pictorial Photography, which is to be made a prominent feature of the International Photographic Exhibition at Florence in the months of April and May next, will contain about a hundred photographs and several original photogravures. We append the names of the exhibitors, by which it can be seen that the section will be fully representative: Messrs. J. Craig Annan, E. R. Ashton, Rev. F. C. Lambert, Messrs. Tom Bright, H. Stevens, W. Crooke, F. M. Sutcliffe, Rev. C. J. Moncrieff Smyth, Viscount Maitland, Messrs. Karl Greger, John A. Hodges, R. W. Craigie, W. Thomas, Leslie Selby, F. Seyton Scott, H. M. Hastings, E. E. Barron, Eustace Calland, H. E. Davis, A. Burchett, R. Belfield, H. Wilmer, Basil E. Lawrence, H. Vivian Hyde, T. Manly, W. M. Dodson, F. Hollyer, Charles Emanuel, W. J. Warren, R. Cocks, and W. Smedley Aston. To Mr. H. E. Davis, who has organized the section, great credit is due for having got together what can easily be imagined will be a worthy display of British pictorial photography for the inspection and study of Italian photographers.

THE March number of the *Camera Club Journal* contains the following announcement: The Committee have under consideration a scheme for removing the Club to much larger premises, and are engaged in making inquiries as to the prospect of attracting a sufficient number of new members to support the undertaking. Should the Committee eventually decide to recommend the scheme, it will immediately be placed before the members, and will be brought forward for their decision at the next Annual General Meeting.

\* \* \*

BRITISH photographers are not alone in the position of having to apprehend and cope with uncalled-for attempts to amend the law of copyright to their disadvantage; their American brethren are just now being menaced in a similar way. One of our transatlantic exchanges tells us that a new copyright amendment of far-reaching importance is now before Congress. The exact text is as follows: "Provided that on and after the first day of July, 1899, no person shall be entitled to a copyright unless the copies deposited with the Librarian of Congress of such copyright book or other article, or the photograph deposited of a work of the fine arts, shall be of such substantial and permanent paper or substance, and ink and impression, as shall be according to such standard as shall be from time to time established and approved by said Librarian." Our contemporary points out that no provision is made in the law for the publication of standards, and, as the law requires that two copies must be deposited with the Librarian on or before the date of publication, an error in not complying with the standards would necessarily result in a loss of the copyright. The American Copyright League has directed its counsel to file a protest against alterations of the copyright statutes which seemed to clothe the Librarian with arbitrary power, not only of establishing a standard, but of altering it at will. Provided that some intelligence is employed in defining a standard for photographic prints, American photographers have nothing to fear from the proposed amendment; the quality of photographic paper is necessarily of the best. We shall, however be curious to note if the desiderated "permanency of impression" includes, or excludes, silver prints.

\* \* \*

IN the course of a letter from Mr. H. Snowden Ward, who is at present lecturing in the United States, he tells us that there

seems little photographically new there except the inclination to approach the Paris Exposition people, through the U.S. Government, with a view to getting pictorial photography recognised as a subject worthy of a department of its own.

\* \* \*

To the well-known house of gelatine-manufacturers, Messrs. George Nelson, Dale, & Co., Limited, of 14 Dowgate-hill and Warwick, we are indebted for a copy of a little book, *Round about Warwick with a peep into the gelatine Factories at Emscote Mills*. The letterpress is by Mr. Alfred Barnard, who writes appreciatively of Warwick, Leamington, Stratford-on-Avon, and other world-famed places in the neighbourhood, around which the glamour of historic interest and picturesqueness is eternally thrown. There are many good half-tone reproductions of photographs in the book, which is sent free on application to Messrs. Nelson at the address above given.

\* \* \*

ABOUT thirty-six pages of the book are devoted to a descriptive illustrated account of the famous gelatine works at Emscote, and portraits of the past and present heads of the firm are given. We learn that the business was established in the year 1837 by the late Mr. George Nelson. The manufacturing buildings cover five acres, and the preparation of gelatine, for photographic purposes, is conducted in one of the factories that is especially set apart for the purpose. Messrs. Nelson's business is, of course, chiefly devoted to the production of gelatine for culinary, confectionery, and cognate purposes, and Mr. Barnard gives his readers an interesting account of the process of manufacture which the raw material, hides chiefly shipped from Singapore to London, goes through in the course of its evolution into the dainty product, gelatine, which has so many invaluable uses in domestic economy to-day. Messrs. Nelson's staff, notwithstanding the elaborate machinery employed at the works, numbers 250; and the relations between employers and *employés* appear to be of a singularly cordial character, Emscote being quite a model village, having a Nelson Club, theatre, and so forth.

\* \* \*

As many of our readers may not be acquainted with the variety of gelatines which Messrs. Nelson, Dale, & Co. prepare for exclusively photographic purposes, we here give mention of each. They are as follows:—*No. 1 Photographic*: a readily soluble gelatine, very suitable for mounting and enamelling photographs, &c. *No. 2 Photographic*: possesses a little less solubility. Suitable for the manufacture of gelatino-bromide and gelatino-chloride emulsion papers, for collotype, and similar photo-mechanical printing processes. *No. 1 Autotype*: prepared especially for the manufacture of the tissue used in the carbon process, &c. *No. 2 Autotype*: useful for the preparation of transfer paper for carbon printing, &c. *X Opaque*: a hard gelatine, capable of absorbing a considerable quantity of water. Useful for collotype and similar processes, and in the manufacture of dry-plate emulsions where a hard gelatine is required. *S. D. P.*: specially prepared for gelatino-bromide or chloride emulsions, either for dry plates or paper. *Amber*: a soft gelatine of value in the Woodburytype and similar processes; also useful as a mountant for photographs, &c. *D. 1.*: suitable for the preparation of dry-plate or paper emulsions.

WE have again to convey to many secretaries of societies who have favoured us with reports of meetings an explanation of the non-appearance of those communications in our pages. It is simply that either the reports contain nothing of interest to the general reader, or that the information recorded is in the nature of a twice-told tale and has grown stale in the telling. We ask all whom it may concern to note that in future we cannot undertake to print reports which are mere repetitions of what have previously been published in our pages.

#### FILM TROUBLES.

THE time is approaching when photographic *débuts* are pondering whether plates or films shall be their choice, the near approach of spring being generally the starting point for camera work. Each of the two has its advocates, and each its advantages and disadvantages. The readiness of chemical manipulation with plates under all circumstances, as opposed to the trouble of developing continuous films, is set off against the incontestable convenience of a roll of sensitive material when travelling away from home with intention of developing, and so on. Our present purpose, though we hold no brief for the film-manufacturer, is to point out some of the small ills attaching to their use, with some methods of avoiding them. This we shall do at some risk of appearing to write for the mere tyro.

Starting at the beginning of the career of the film, we may note that we have seen a good number of films injured simply through carelessness in starting the unwinding of the spool. If the first attachment of the end of the film to the unwinding spool be not done so that the unwinding film lies quite square to the store spool, the film, as it is gradually unwrapped, will be crimped at the edges, the creases sometimes extending far enough to injure the details in the film, but always to an extent that forms a danger of starting frilling in development.

A mishap with daylight spools, not uncommon with beginners, will happen when cutting up the film into sections for developing. The roll is laid down on the table, and, when taken up, something seems to have gone wrong, "the maker has put the film the wrong side out, and hidden the numbers printed on the black paper." The cutting, however, is done against the marks for the purpose, and, when development takes place, a number of views are found to be cut through the middle. This happens through the film having been allowed to wind itself once round the whole roll, and so reversed its relative position. When this happens for the first time, the puzzle is so complete as to be more like a conjuring trick. We have seen many views so unconsciously bisected.

With regard to the various modes of arranging the film for development, we will not touch upon that at the present time. It would afford matter enough for several articles to show the relative merits and demerits of cutting up the film into pieces each representing one view; cutting them into sets of two, three, or more; developing them attached to glass, or detached from any support; on rollers, or flat in long dishes, &c.

With regard to the plan of attaching lengths of films by means of the strips of adhesive caoutchouc tape described by us some time ago, the plan has been well liked, but a difficulty has been experienced through a portion of the rubber attaching itself to the back of the film, and being difficult to remove. The remedy is to lay the film, back uppermost, upon a sheet of paper, and, holding it firmly down with one hand, push the sticky rubber firmly forward with one finger towards the edge

of the film. It will, if properly done, collect in little balls and separate itself; any slight smear remaining may be taken off at once by a slight touch with a pledget of cotton-wool dipped in benzole.

We have had complaints of the frilling of films with the continuous lengths far more than with plates. This is a most serious evil. The best remedy is to keep a sharp look-out for five or ten minutes after washing, and, if the slightest signs of incipient frilling become manifest, to at once immerse the films in a five per cent. solution of formalin. Usually all further frilling will at once be arrested. Should, however, frilling have taken place to an extent threatening the whole of the gelatine surface, the simplest plan is to "let it go"—actually assist the frilling—and, when the whole film is loosened from its celluloid base, to insert a glass plate underneath it and take it up film and glass together, gently drain, and allow them to dry. There will then be a glass instead of a celluloid negative, and, usually, of slightly enlarged dimensions. *En passant*, let us say that it is better, when "collecting" the film on the plate, to let one edge slightly overlap the edge of the glass; there will then be no risk of the whole film slipping away when the glass and film are put up to dry.

Before leaving the subject of frilling, it is desirable to point out that the formalin remedy must be applied at an early stage, for, if, as in cases which have come under our notice, a considerable portion, say a third or a quarter of the film be loosened and then the formalin be applied, it is true that in all probability further frilling will be stopped; but that part already detached will be expanded, and will, upon drying, show wrinkles, and, further, will appear of different density from the normal portion of the negative. When this is found to be the case and the formalin is made use of, it will be impossible to detach the film altogether by any after-process for the purpose of attaching it to glass, as no method that we have met with, short of dissolving the celluloid away, will enable the gelatine to be separated; so firmly does the formalin seem to keep it attached to the celluloid foundation. Indeed, even were it possible to detach it, this portion would be non-enlarged and the difference in density would still be palpably manifest, and the wrinkling of the enlarged portion could not be got rid of even by immersion in methylated spirit, which, as is well known, will reduce under ordinary conditions a swelled film to its original dimensions, as in the method of transferring a film by the aid of hydrofluoric acid.

We find that a single article will not suffice to include all difficulties we should like to treat, and we purpose, therefore, to take up the subject again on a future occasion.

**The Recent Cinematograph Accident and the County Council.**—It is not always that we agree with the doings of the London County Council, but the regulations they have framed, together with the conditions laid down by the insurance companies, no doubt averted what might have been a serious accident at the Hammersmith Theatre of Varieties, which we reported last week. A fuller account tells us that everything was ready at hand in case of accident—a fireman with hose, wet blankets, &c.—and it took but a few seconds to extinguish the flames. As the apparatus was behind the screen, the audience knew nothing of the accident till told by the manager that the apparatus had gone wrong. Had the cinematograph been placed in the auditorium, those present would have seen the blaze, and perhaps a panic would have been created, and with serious consequences. These continuous accidents, though fortunately hitherto without any very grave results, do not tend to inspire confidence in the general public, who, in the case of

an alarm have in mind the Paris catastrophe a year or two back. When shall we have a non-inflammable film that can be used in the cinematograph? There is a fortune awaiting some one; for, if such a film were forthcoming, there is little doubt that celluloid films would be prohibited by County Councils.

**Poisoning by Cyanide of Potassium.**—Cyanide of potassium is not much used in photography at the present time, except for fixing collodion negatives, positives, and ferrotypes. In the old wet-collodion days, when it was to be found in every dark room, suicides through it were by no means uncommon, and there were instances of its being swallowed in mistake for something else. In all cases that have come under our notice death occurred within a very brief period—generally a question of minutes. On Friday last an inquest was held on the body of a man who had committed suicide by taking cyanide, and the remarkable thing in the case was that he lived so long after swallowing the poison. It is stated that he drank half a pint of the solution. A doctor was sent for, who refused to attend, but advised the man's being taken to the hospital (St. George's). Now, from the South Kensington Museum, where the occurrence took place, to the St. George's Hospital is a long distance, yet the man was alive and conscious when he arrived there. It is obvious from this, that either the half a pint of solution was very weak, or that it was made with a very inferior cyanide.

In formulae for fixing collodion negatives, glass positives, or ferrotypes, so many grains to the ounce of water are given; such is also the case with a solution for "restoring" Daguerreotypes; but it is obvious that much must depend upon the cyanide itself. In a wholesale price-list now before us we find cyanide of potassium quoted as thirty, forty-five, seventy, and ninety-five per cent., the price varying from one to three shillings the pound, while the pure crystallised salt is quoted at twelve shillings a pound. Old workers, who use the cyanide for either of the above purposes, usually keep a strong solution of the salt of indefinite strength, and dilute it in such proportion as may by experience be found necessary. We have alluded to this matter because we have heard that some have failed in cleaning Daguerreotypes when using the strength given in formulae, while others have spoilt the pictures with a similar quantity of the salt.

#### **Alleged Discovery of Pictures at Hampton Court.**

—An account has been going the round of the papers during the last two or three weeks of the unexpected finding of some valuable paintings at Hampton Court Palace. Now, as a matter of fact, they were never lost, as their existence and whereabouts were known all along, and described in old guide-books. They are painted on the walls of Queen Anne's Drawing-room, but they had been covered with canvas and other pictures hung over them, because they were considered of little merit at the time. The paintings are by Verrio. They are now to be repaired, the nail-holes made in hanging the other pictures are to be filled up, the work made good, and the paintings restored to their original condition. The pictures which hung over these "recently discovered paintings" have been removed to the walls of Kensington Palace, which is shortly to be opened to the public. Amongst those removed is West's Collection, in which is included the *Death of General Wolfe on the Heights of Quebec*, that for many years hung on the walls of the Queen Anne's Drawing-room.

**Is it a Forecast?**—On several occasions, when the Budget is "in the wind," suggestions have been made that there should be a tax on photographs; but, of course, the proposal, up to the present, has received no serious consideration. In last week's *Punch* there is a full-page illustration by Mr. Linley Sambourne, below which is: "I shall have to take it out of some of 'em. The question is— which?" The picture shows the Chancellor of the Exchequer, and the background and foreground are made up of a great variety of

articles, such as pipes, cycles, pianos, &c., and cameras. It is noteworthy that while the different things depicted are mostly confined to one of each, there are four or five cameras—hand and stand—shown in the picture, and they are given great prominence. From this it would seem according to Mr. Sambourne's idea, that some of the deficit to be dealt with in this year's Budget may be obtained from photography. Let us hope that the Chancellor of the Exchequer's and Mr. Sambourne's ideas do not run in the same groove. Still the former will "have to take it out of some of 'em."

### JOTTINGS.

I AM told that the first paragraph in my last month's Jottings was not quite accurate. "Exit Bennetto; exit Sellé," said I. It appears that the Sellé process still occupies the stage. A company to work the Doctor's three-colour patents is in process of formation, and the prospectus may shortly be expected. Three-colour colotype, three-colour films superposed on glass and paper, and three-colour block work are to be the Company's leading lines, to which additions are to be made by means of some recent patents that have been taken out by Dr. Sellé. This reads like business, at any rate.

And, indeed, the sooner we get to business in some of these much-discussed colour schemes the better. There has been quite enough said and written about them, so that we could do with a little less of the rattle, and more of the 'osses. If all I hear be true, a colour boom is imminent. Messrs. Lumière are said to have perfected a three-colour bichromate (not gum) process, and the results are very highly spoken of. I am told, too, that something remarkable in the way of printing machinery giving a hitherto unattainable degree of accurate registration is likely to be introduced. Put your money on colour, would seem to be the word for those who have faith in the future of trichromatic printing.

How heavily the photographic paper trust in America presses on the manufacturers of sensitive printing surfaces may be realised by the following extract from a letter which I have just received from the head of a well-known house in the States: "Except we can get the stock of the other paper-makers outside the combination after our stock is exhausted, we shall have to shut down and be stamped out of existence." As my friend says, the American manufacturers are worse off than the English makers of P.O.P., who are not menaced by a paper monopoly, but by the lesser evil of a rise in prices. Fortunately trusts do not flourish on English soil, and the policy of forcing up prices has over and over again been proved to be one of doubtful wisdom.

The subject of illicit commissions, or, as it is more popularly put, bribery in business, has lately engaged the attention of a Special Committee of the London Chamber of Commerce, and the revelations that were made as to the great extent in which palm oil is used in procuring orders for goods from managers and subordinates is enough to make the hair of every head of a trading firm stand up straight. The evidence given before the Committee, and the latter's findings, point to the conclusion that the entire commercial world is honeycombed with this form of dishonesty. I do not see photography named in any of the published accounts of the Committee's report; but some years ago it was notorious that dry-plate makers were very often at the mercy of dishonest operators. It is so easy to fog plates, or not to fog them, that the choice of a brand of plates could, without difficulty, be made to hinge upon the amount of the *douceur* a dry-plate maker might be willing to present to the operator. With the growth of competition, and the erection of dry-plate making into a great industry, the evil state of things I am alluding to has died out, but my readers can take it from me that it once existed in a very acute form.

I can endorse what was said on p. 121 relative to the interesting character of the lectures recently delivered at the Camera Club. The Hon. Secretary, Mr. Godfrey, cannot be too highly praised for the skilful manner in which he caters for the variegated tastes of a "half scientific, half artistic" body, with a membership of between seven and eight hundred. The Camera Club, in fact, to judge by external appearances, is slowly but surely climbing up the hill of prosperity, and it is to be hoped that there will be no break in the continuity of the present admirable system of management. The fact that consideration is being given to the question of obtaining larger premises for the Club is a very favourable sign. It points to the supposition that those at the head of affairs have faith in the Club's future as a social and photographic force.

To me the chief charm of the Club lies in the fact that it is a harbour of refuge from the petty but irritating little storms and controversies that are continually agitating what it is customary to term the photographic world. Camera Club members do not allow the "sustained splendour of their stately lives," as the Beaconsfieldian phrase runs, to be interrupted by haggle and clamour over such awe-inspiring topics as Affiliations, Yorkshire Unions, Professional photography and the Royal Photographic Society, the Royal Photographic Society's Exhibition, the Salon, and so forth; and at the meetings you do not hear the same people saying the same things on the same subjects week after week, year in year out, as at some other societies connected with photography which I could name. In short, as a body in which a great deal of good photographic work is done in a quiet and unostentatious way, the Camera Club has wrought out a unique position for itself, and increasing prosperity and success is only its due in right of the very effective manner in which it fills that position—that of the principal social centre for photographers in Great Britain.

The bitter cry of the photographic assistant, who finds it difficult to obtain a situation, is again heard in the land. You cannot help feeling sorry for men who go through the dreary round of answering advertisements only to meet with non-success. It is cold comfort for them to know that there are tens of thousands of men in other walks of life similarly situated, as a study of the daily newspapers' advertisements serves to show. But the great army of unemployed clerks, drapers' assistants, and so forth, have to suffer and be silent; they have no sympathetic journal which allows them to ventilate their grievances against those callous people who advertise under initials and have no eye for photographic genius or talent; for this is what the complaint of the dilemma'd assistants really amounts to.

But are professional photographers so inhuman and callous as these disappointed assistants would have us believe, and are these latter unsuccessful applicants for operators' berths so skilful as they think themselves to be? Alas! Time after time I have been given the opportunity of running over the letters and "specimens" of those who are seeking situations in photographic studios, and, oh, the tragic illiteracy and photographic incapacity and ineptitude which hundreds of these self-styled "first-class" assistants betrayed! Then, as to professional photographers as a class, I know some hundreds of them personally, and better, kinder-hearted employers there could not be. A professional photographer is very much like other business men, he knows good work and good men when he sees them. I am reluctantly obliged to say that these dilemma'd assistants probably owe their present position to the fact that they are not really the clever operators they fancy themselves to be. Talent is by no means a drug in the market. I fear there is no escape from the old proposition that good men will always get to the front, and that the only way for these assistants to escape from their dilemma is by persistent hard work and study, with the ultimate end of making themselves *masters* of photography. The consciousness of ability carries with it confidence in being able to demand adequate monetary recognition of it.

Those who expected that, as a result of the agitation which has been going on for the last six months for an alteration in the scope of the Royal Photographic Society's annual Exhibition, next autumn's display would present a material difference to its predecessors will be disappointed. That Exhibition will be run on the usual lines, and a minuter classification of the photographs, which many have advocated, will not be attempted. No special class will be created for the "usual thing" or the "show-case" photograph, as commercial work is variously termed, and the pining professional who cannot get his every-day work accepted and hung will be left pining. There is talk of securing the New Gallery for next year; that fine suite of rooms would give every opportunity for an exhibition in compartments, if it is found desirable to make any change in that direction. Probably by that time the agitation to which I have referred will have died out. In the mean time it may be worth while repeating that in the Society's new premises the large room could be well utilised for small exhibitions, one-man shows, and so forth, so that those who are shut out of Pall Mall may yet find the chance of having their work brought before the public, and the complaint that professionals not in the forefront of the movement get no opportunity given them of having their productions hung will thus be removed. COSMOS.

#### LENS-TESTING.

ABOUT two years ago, Herr W. Zschokke, at Messrs. C. A. Steinbille & Sons, published the details of a system of lens testing, which gives the principal qualities of a photographic lens at a single exposure. The test object is an evenly illuminated white surface with a system of co-ordinates, zero being at the height of the lens; parallel to the axis fine lines are drawn at intervals of 20 mm., and each space of 10 cm. is numbered on both axes. A studio camera is used the screen of which is set at an angle of 75° instead of normally to the optical axis, and at such a distance that the image obtained is one tenth of the original size. The optical axis is perpendicular to the object and the lens is sharply focussed at o. The necessary inclination is given to the screen by rotation upon a vertical axis. The plate being exposed in this position, the image formed of fine lines will serve as a measure of the difference between the visual and chemical foci, astigmatism and curvature of the field. The distance of the screen from the test object will give the focus.

Herr W. Zschokke, in the current number of the *Photographische Correspondenz*, mentions that, in using the system at their works, they have made the following improvements. These do not affect the principle, but add to the accuracy of the results. The exactness of the method depends upon the correct determination of the optical axis in relation to the object and screen, and means must therefore be adopted to eliminate errors in the construction of the camera. A circle, 5 mm. in diameter, is drawn upon the test chart at zero, and a metal ball of the same diameter, is suspended from a bracket in front of the circle at the same height. The ball may be moved vertically or laterally, and is adjusted to cover the circle exactly. A telescope, with cross lines at the eyepiece, is screwed on to the camera in the lens flange, and, by means of screws, the camera is so adjusted that the circle, bullet, and cross lines exactly cover each other. The telescope is then replaced by the lens. As the camera screen is movable in both directions without disturbing the baseboard, it may be adjusted at an angle of 75° with the optical axis, as well as vertically, and this should be done with great accuracy. With the original test chart, if the astigmatic difference in one lens equalled the curvature of field in another, under a given angle, it would be impossible to decide which of the two gave better definition.

A similar difficulty could arise as to definition at the centre. This difficulty is eliminated by drawing, parallel to the axis of the abscissæ, about 20 lines  $\frac{1}{2}$  mm. broad and  $\frac{1}{2}$  mm. apart. Adjacent to these, two other sets are drawn, which are respectively  $\frac{1}{4}$  and 1 mm. broad, with corresponding spaces. Along the axis of the ordinates similar sets of lines are drawn horizontally and vertically. If the lens gave absolute definition with tenfold reduction, these lines would measure  $\frac{1}{20}$ ,  $\frac{1}{40}$ , and  $\frac{1}{80}$  mm. in breadth; but, as this is not the case, we may say, according to the distinctness of the lines, that the definition of the lens is  $\frac{1}{20}$ ,  $\frac{1}{40}$ , or  $\frac{1}{80}$  mm., as may be. The whole of the results obtained by this system may be expressed numerically or graphically.

#### OVERHAULING APPARATUS.

THE time is now arriving when photographic apparatus that has lain dormant during the winter months will be unearthed, with the object of again being taken into use. Much of it, unless more care has been bestowed on its storage than is often the case, will be found in a different condition from what it was when put away. If, for example, the apparatus has been kept in a damp attic, the probability is that the shutters of the dark slides and other sliding woodwork will not be found to work freely. When that is the case, force is often employed and the aid of glass paper invoked to ease the parts. That is a mistake. Force will often start the joints, and glass paper will make the parts work too freely when the wood acquires its normal condition. What should be done is to put the apparatus, untouched, in a tolerably dry place—such as an ordinary living room—for a few days. In that time it will, doubtless, have recovered its original condition. If heat were applied to hasten the drying, the probability is that the wood would "cast," or warp; then still more serious trouble would ensue. Sometimes the bellows of cameras which have been tightly packed will stick if they have been put away for long in a damp place. In that case the bellows should be carefully distended and allowed to remain undisturbed in a dry place for some days. If, after that, the varnish on the leather seems tacky, which is sometimes the case, it should be well rubbed over with French chalk. If the things have been stored in an unusually damp place, it is possible that the glue will be seen exuding from the joints. This is a more serious matter still, and the only remedy then is to put the apparatus in a situation where it may dry still more slowly. Then, as the wood shrinks, the glue may go back again into the joints, but, in any case, it should not be scraped off till all is absolutely dry. Although apparatus may suffer by storage in damp places, much may be done in the way of ameliorating the damage by careful treatment when the injury is first discovered.

#### PHOTOGRAPHY IN RELATION TO ART.

DOES photography bear any relation to Art at all? asks Mr. A. W. Goodman in the *Windmill* for January. This is a much-vexed question, as old certainly as the invention of photography, and one that always has been, and probably always will be, answered by different individuals in different ways. That it is scientific in origin cannot be gainsaid; that it is largely mechanical in working is also true. But, none the less, it is increasingly the handmaid of Art, and is often conspicuously used by those artists who are the foremost in denying it any artistic possibilities whatever. What, then, is its real place, if any, in the domain of Art? Is it to be eternally a hewer of wood and a drawer of water to its more fortunate sisters, who are admittedly comprised in the fine arts? Is it destined for all time to be a sort of Cinderella to the painter, to the etcher, to the worker—whoever he may be—who depends solely upon the cunning of his hand and to the accurate observation of his eye for the effect he wishes to produce? Or, is there potentially a Prince in reserve who will some day fit the glass slipper on the now lonely and despised drudge, and declare that she, too, has a place, and that not a small one, in the polished temple of Art—spelled with a capital A?

These are questions at least worthy of discussion; and, so far as the severer class of critics is concerned, it may very well be that they are either ignorant or oblivious of the vast and rapid strides made by photography during the lifetime of the present generation. Assuredly, the counterfeit presentments of themselves with which our grandparents were content were not "artistic," whatever other qualities they possessed. But, as there was a time when the earth itself was without form and void until the Great Architect of the universe breathed upon it, so there has been a time when every invention or discovery in the whole history of the world has been crude, incomplete, and imperfect, until improved upon by the successive working of master minds. Photography is no exception to the rule. "Art," the poet tells us, "is long, and time is fleeting." The time of photography, however, has been painfully short, when judged in relation to Art, which has practically been co-existent with the existence of man, and we have already travelled far from the stock properties and stiff, ungainly poses of the earlier workers in the field. The thoughtful observer, as he mentally traverses it, may well marvel that so much has been accomplished in the direction of infusing into the dry bones of what was, by origin, a purely mechanical process, something of the flesh and blood of a living Art. Art may not have stooped to photography, but has not photography extended a hand, all too unwillingly clasped, to Art? There is, at least, as much difference between the simpering girl, leaning over a rustic stile, of a bygone generation, and the average platinotype portrait of to-day, as there is between the first form of the velocipede and the latest bicycle, fresh from the Elswick or the Beeston works. And, although some of the difference is, no doubt, due to improved mechanical processes, a great deal more is almost demonstrably due to the general advance in art culture that has

been so notable a feature of the Victorian era. Beyond that, it must be borne in mind that some, at least, of the mysterious processes by which the pursuit of photography is attended are not only artistic in aim and result, but are themselves "Art" pure and simple. Take retouching, for example. The good retoucher is, no doubt, born and not made; but the success of retouching, and with it the success of the finished photograph, depends almost entirely on a nicely balanced perception of light and shade; on a thorough knowledge of the anatomy, at least, of the face, and preferentially of the entire figure; on the value of modifying and softening shadows, or, in short, of generally supplying the deficiencies of Nature with the resources which Art has placed at our disposal.

It is all very well for Othello to say in the play, "Paint me as I am," or for Cromwell to have insisted upon Sir Peter Lely depicting him with all his warts, as he is reported to have done. But these are exceptional demands on the part of exceptional men; and it may be taken for granted that the generality of people do not desire to appear to their friends exactly as they are, but rather as they may be, when seen through the golden telescope of love in a somewhat idealised shape, and with one's little imperfections and blemishes softened and subdued by a kindly Art. Nor is there any impropriety in all this; for, while it is no doubt true that where Nature has been bountiful Art can do comparatively little towards improving it—on the principle of not being able to "refine the lily" or "paint the rose"—in those more common cases where Nature has been niggardly, Art may and can do, legitimately, a very great deal towards redressing the balance. In other words, some of those defects which are exaggerated by the camera can be restored to their proper sense of proportion by the aid of the skilful retoucher. In the nowadays little-read fables of Gay there is a story of an artist who determined to let truth, and truth alone, sway his brush. He must certainly have been a forerunner, if not indeed the originator, of the Realistic school of Art! But mark the sequel. His sitters fell away, until the unhappy but conscientious artist was reduced to penury. He then bethought himself of a new expedient, and, placing in his studio busts of Apollo and Venus, he fashioned all his male sitters after the one and his female after the other. Crowds soon flocked to him again, and brought both fame and fortune in their train. There is no Realistic school in photography; or, if there be one, it is of the minutest proportions, and human nature is still pretty much what it was in Gay's time, and, so long as this is the case, the calling of the retoucher will never be superfluous, but will continue to endow the creations of science with something of the beauty and refinement of Art.

It would, however, be absurd to claim for photography that it is necessarily artistic. That it may become so, however, is scarcely open to serious question. Do you doubt it? Look on this picture and on that. This one is flat, hard, crude, without either tone, distance, or other quality to recommend it; that one, on the contrary, is instinct with life. The component parts bear adequate relation to one another, the point of view is well chosen, and the general effect is soft and pleasing. What makes the difference? Surely it is the artistic feeling behind it—the subtle, undefinable something, call it what you will, that distinguishes between success and failure. That photography has painful limitations must, of course, be allowed, and nowhere is this more apparent than in the treatment of the nude. What, with brush or pencil, is graceful and decorous becomes neither the one nor the other when exposed to the manipulations of the camera. Nor is it possible in the treatment of the half tones to accomplish satisfactory results by means of photography. Your sitter may be represented as either being fair or dark, but can scarcely appear to one's friends, as is perhaps actually the case, with no very decided bias in either direction, but with some features common to both.

But, after all, this is only a small part of the whole, and there are compensating advantages elsewhere in the absence of faulty drawing and defective colouring. The artistic sense to the worker of whatever kind is what refinement is to the natural man. You may be born with it, or, more rarely, you may acquire it by slow and painful process of education; but unless it is there—be it intuitive or acquired—your work will never possess a high quality. "But I don't see so-and-so," said a critic to a well-known painter once. "No, Madam," was the quiet reply, "don't you wish you could?" To him that hath eyes to see, let him see, is the natural correlative of "to him that hath ears to hear, let him hear." An amusing illustration of the dignity of photographic art, in this instance falsely so called, came under the writer's notice once in an obscure village in Norfolk. A peripatetic photographer, with long hair and a blue necktie, and a generally æsthetic appearance, had been taking photographs in the orthodox manner, when "to him entered," as the old playwrights would have said, two rustic damsels anxious to pose. He was not one of your ordinary "artists" to whom nothing is uncommon or unclear, and a few searching inquiries elicited the information that the fair ones expected the process completed at one sitting, and to be able to take the completed work back with them. The offended knight of the camera drew himself up with an injured air. "Do I look like a man," quoth he, "who would take a photograph on glass?" And the would-be sitters retired abashed from the great man's presence.

Now, I mention this incident, because it seems to me to represent a somewhat common confusion of thought. The humble worker is regarded as the offence of all things, to be looked down upon by the pro-

fessional from a more or less giddy height. Shall I be thought unduly daring in at once laying claim for amateur photography not less, but more, artistic quality than the professional? The reader smiles, as he recalls many of the grotesque and hopeless failures of his friends to produce even a decent semblance of his features; but, nevertheless, I am perfectly serious in contending that, the conditions being equal, the despised amateur, who knows his business, will generally produce more artistic work than his patronising brother professional. I am not, of course, referring to the Mendelssohns of the profession, who are pretty much *sui generis*, but to the ordinary average worker. Is it strange that it should be so, when it is borne in mind that what is the hobby of the amateur is the means of living of the professional, and, while the former can pick and choose his models and his landscapes, the latter must perforce take all and sundry that present themselves?

I said just now that artists were indebted to photography. It is only fair, however, to add that photographers are under an even greater obligation to Art. Nor are they slow in acknowledging it. One of the leading photographers in London assured me not long ago that he spent every Sunday morning in an artist's studio, mastering the technique of art, and building up the figure for himself, point by point, so that he might be the better able to invest his work with the artistic quality he felt it otherwise lacked. And is not this receptivity of mind, this readiness to learn from whatever quarter, one at least of the many signs which distinguish the true artist from the false? Apelles himself was not above learning from his cobbler, while he confined himself to the domain of his last; and one of the truest artists, in the largest sense of the term, the late Mr. John Addington Symonds, himself told me the following story, which, I believe, has not previously appeared in print. The late Master of Balliol, being on a visit to him in his Swiss mountain home, their conversation was on one occasion interrupted by one of those peasants to whom he was always so accessible, and of whose friendship he was justly proud. When the man at length departed Jowett turned to his friend with the playful remark, "I wonder, Symonds, that a man of your cultivation and refinement can find anything to interest you in the conversation of a clodhopper like that!" "Ah, there you are wrong," was the smiling reply; "that man who has just left me is a perfect authority on the subject of horses, and, if I talk to him about these, I learn a great deal of which I was ignorant before."

There spoke the true artist in his readiness to be all things to all men, that he might by all means save some from the merely routine and mechanical, and lift them to the higher plane of those who, having eyes, see not merely "men as trees walking," but with the unclouded vision of a purer and firmer faith.

But to return more strictly to the vexed question before us; it is, no doubt, one in which opinions will always differ. There are those who contend with Mr. Horsley Hinton—himself no mean authority—that "to such an extent may relative tones be wholly altered, and even the delineation of objects modified, that it may justly be said that the photographer's method is only a little less facile than the water colourist's; and lack of artistic instinct and training is more responsible for the usually inartistic results of the photographer than the inadaptability of the process."

Others will continue to say "non content" to any demand for artistic recognition on the part of photography, and between the two extremes, perhaps, there will be some who will be disposed to say with Ovid, "*Medio tutissimus ibis*."

#### FLOWER PHOTOGRAPHY IN A GARDEN.\*

Judging from the number of articles on the subject which have appeared in the papers lately, there seems to be quite a boom on in flower photography. Fashions come and go in such work as in other things; the success of one leads others in the same path, and hosts of imitators follow. We have had, and still have, sunsets innumerable, mists and marshes, more recently birches, brackens, and flowers. Perhaps we are on the high road to a more cheerful outlook, when exhibition walls will not for ever frown upon us with representations of gloomy dawns, fading light, and lurid skies. May it not be that we have come through the darkness of night, through the sombre woods, and are greeted by the flowers of a brighter country beyond?

Sunshine and flowers are all too rare in this grey land of ours during many months of the year. Should we not recall them to our minds more than we do?

Perhaps the hot summer and autumn of 1898 may have had something to do with the awakened interest in flower photography. The beautiful clear light of many lovely days tempted the ardent worker to sally forth in search of the subjects which he felt must be lying ready to hand at every turn of the way. But the heat of a pitiless sun soon drove him homewards again to find rest and coolness in a shady garden, and there he came upon a bevy of old friends waiting to greet him. Roses, lilies, anemones, and hosts of others crowded round him. He had only to choose, and, having once begun this fascinating study, and found how

\* Paper by Miss Christian H. Curle, to which the silver medal of the Edinburgh Photographic Society was recently awarded.

admirably it was suited to while away a long summer's afternoon and leave a sense of good work done, he was not likely to relinquish it all at once. From the point of view of a lady photographer anything that can be experimented on near home is of immense advantage in summer no less than in winter. A camera of any size is a fairly weighty burden, so are the necessary dark slides. Skirts, however "sensible," require to be held up now and then, and the small hat which goes comfortably under a black cloth does not, without the help of a parasol, keep off the sun; so that, to be properly equipped for an expedition, quite two, if not three, pairs of hands are necessary. It must be admitted that good-natured friends can often be induced to help, but on a drowsy afternoon they are perhaps more inclined to slumber under a shady tree and offer such a suggestion as "Why not try a group of us all here if you want to photograph something?" Where, then, could pleasanter work be found than in a garden?

Perhaps some recent competitions in the gardening magazines may have helped to stir up an interest in this branch of photography, but I am inclined to give a full share of praise or blame to the heat of last summer.

I advocate working in a garden, for I think that is much to be preferred to bringing flowers indoors. There, unless growing in a pot, they must be put in water, otherwise they soon droop and flag, and the handling they must undergo in being arranged does not help matters. When in a vase, a stem cannot always retain its natural curves, while a group of flowers becomes a bunch of which one has lost the individuality, if it may be called so, that it had when growing. The difference between a plot of snowdrops in the garden and the same flowers when cut and put in water illustrates what I mean. A blossom or spray taken as it grows is much more likely to look graceful and natural than when arranged, however carefully, in a vase. Undoubtedly, an interesting field lies open to any photographer who has a love of flowers and takes a real interest in their variety and habits. By studying these in a garden a series of photographs might be gathered forming a most interesting record of the year. Any flowers that have grown to great perfection, those rarely met with, old-fashioned favourites in danger of being forgotten, or those successfully bloomed for the first time, should be carefully selected and included; and the result might easily be that, while the whole formed a collection interesting and perhaps valuable to a botanist, each study by itself would be an artistic picture.

Now is a particularly favourable time for such a project. Gardens and the plants in them are allowed to be more natural than a few years ago; ribbon borders have given place to herbaceous borders, and everywhere more freedom of growth is encouraged. The style of flower in favour has changed to suit these altered conditions. For instance, the stiff formality of the dahlia of other days has given place to a looser, freer, more graceful form of flower. Single roses have crept in where once only the most perfect double forms were considered worth looking at; the much-loved camellia has lost much of its old popularity, and in other families the tendency is the same. The favourite flowers are no longer those which remind us of the bouquets our grandmothers so patiently modelled in wax. An ideal garden of to-day is a charming medley of plants, old and new, growing as much as can be permitted without restraint—creeping, climbing, festooning where they will, carpeting the ground and covering the trellises with rich, tender colour, filling the air with delicious scents. It is not quite the garden of Bicon's dreams. True, we cherish the "stately hedges" if fortunate enough to possess them, but they have no "little turrets" to hold "cages of birds," and, happily for the photographer, no "broad plates of round, coloured glass gilt" for the sun to play on.

What a vision of distracting high lights! One great advantage of working out of doors is that the brilliant light permeating the petals of flowers helps to show their delicate transparency, and in many cases to give truer colour values than could be looked for indoors. Of course there are difficulties too. The chosen flower or spray does not always grow at exactly the right height for the camera, nor catch the light at a good angle. Shadows of leaves may fall upon it, or it may sway beneath the weight of numerous energetic bees, whose well-known habits of industry apparently make it impossible for them all to stay still a single instant. Some flowers they persistently haunt, such as the Erigeron or sea holly. Tempted by the beautiful silver greys and blues of this handsome plant, I tried one day to photograph a branch of it. But no less than nine bees were there before me, and, though they might have helped to make an interesting picture had they been still, the constant movement of some of them kept the plant trembling and quivering so that an exposure of proper length was impossible. The question of suitable elevation has also to be considered out of doors, flowers which grow low down on the ground being much the most troublesome to manage. No amount of careful arranging will make a group of, say, giant colchiums (autumn crocuses) look natural when out and brought into the house. A typical group of them must show the large stately flowers at every stage of their growth, for so they are usually seen in the border when at their best. The full-blown ones, opening wide to the sun, show the beautiful striped veining of their petals; the half-grown, of a deeper shade of mauve, still partly closed; and, lastly, the round fat buds pushing their way like mushrooms through the soil. Together they make a beautiful group; but to reach them the camera must be brought as low as

possible—so low that careful focussing becomes extremely difficult, and the poor photographer is obliged to lie almost full length on the ground to see the ground glass at all. In this trying and back-breaking position he is apt to overlook the fact that the camera has included one of its own legs in a curious distorted fashion in the picture.

Snowdrops present the same difficulties, but they can often be found growing more or less wild on the steep bank of a glen, and then can be got at very easily. In this case they often have a beautiful natural background of dark green wood ivy to show up the purity of the dainty blossoms. When a flower grows too high up, and it is not possible to raise the camera sufficiently to be on a level with it, I have found the best plan to be to cut the spray with as long a stem as possible, and tie it to some support which brings it to the proper height. Pea-sticks may be found most useful for this. The length of stem cut admits of the flower retaining its natural pose, and also allows the buds, thorns, leaves, &c., to be clearly seen. Sometimes a little judicious thinning of the leaves is advisable. A piece of yellowish-brown pasteboard, such as is used for packing books, makes an admirable background, and, if there is any difficulty about propping it against another pea-stick, it can easily be held in the hand while the plate is exposed. No amount of movement matters as long as the pasteboard is large enough and does not touch the flowers to shake them. A lighter or darker background can be had according to the distance it is placed behind the subject. When very near, it will in most cases be darker, and care must be taken that the shadows cast on it are not too distracting. If soft and slightly confused, they may add greatly to the beauty of the picture.

An ideal place for flower photography is a trellis covered with flowering creepers. Then there is a great choice of beautiful blossoms, sprays, and branches, and the background is easily arranged behind them. Nothing more delightful could be found than a group of some of the single roses which have come into favour the last few years, such as the Penzance briars, Macartney roses, Paul's Pillar whites and carmines, and many others. They are most graceful and decorative in their growth, a thousand times more so than the full, well-formed double roses which are the gardener's delight. A charming study can be made of the flowers of such a rose—a bud, perhaps, or a seed-vessel or two, with a few grey-green leaves, and some of the stem showing to give as much as possible the character of the plant. The background should be used here, for, though a thick screen of green looks well enough on the ground glass, it may be very spotty when reproduced in black-and-white. Brown paper does very well if the pasteboard is too heavy, but it must be free from creases. The best effect is generally secured when the light falls on the flowers from the side, and in most cases bright sunlight is not advisable. The very deep shadows thrown by it rather hide the true form and delicate roundness of the blossoms, and the faint half-shades may be lost, while the high lights tend to become too dense. This, however, can hardly be laid down as a rule, for plants differ so much in habit and colouring that each must be studied and taken in the way that suits it specially. Speaking generally, the flowers that can be most successfully photographed are those of a pale colour, and not too solid a growth. The blossoms of apple, cherry, and peach fulfil these conditions, and at the same time grow in most beautiful sprays. Almost any one taken at random makes a picture of itself. Single roses, Japanese anemones, irises, the common pink and white mallows, and many others make charming subjects for the camera. One and all, they look their best life size. Working with a half-plate camera, a good deal of selection is required to find just what will suit the proportions of the plate and fit into it.

In making a study which is to be of botanical interest, care should be taken to show any special characteristics of the plant. Whatever helps to recall the living, growing plant to the mind adds an additional value to the picture. Sometimes the backs of the leaves are very distinctly veined, as in the Japanese rose, *Rosa rugosa*; they are more grey in colour than the other side, and the veins stand out very prominently. These catch the light prettily, and it is not difficult to show the texture of the leaf. The same rose has very large handsome hips, which should not be forgotten.

The seed-vessels of many plants are beautiful and distinctive; none more so than those of the physalis or winter cherry, some irises, honesty, or the pods of the common broom, which are of a dark grey-brown colour, covered with fine downy hairs.

So far, only flowers or sprays have been under consideration, but a whole plant may make a very striking picture, such as a well-grown bush of spirea, *Grossularia folia*, all hung over with its drooping bunches of creamy flowers, or the more upright variety, *S. gigantea*, with its tall spikes shooting up boldly from among the leaves. Groups of tall lilies or foxgloves make a delightful study, all the more so that they have a pleasant way of frequently growing in front of dark bushes, which make an excellent background for them. Large poppies of pale shades should be included in our list, but the red ones are disappointing. Here we come face to face with the great weakness in flower photography, the impossibility of reproducing colour. In dealing with flowers which are white or of pale shades it is not felt so much; but, when we come to brilliant scarlets or glowing reds, the wisest thing to do is to pass by on the other side, and regretfully allow that, until we triumphantly arrive at perfected colour photography, one of the greatest beauties of the garden remains unattain-

able by the craftiest camera. In photographing flowers the focussing is not such a simple matter as in landscape work. Everything is at such close quarters that the distortion of parts not in focus becomes very pronounced unless a small stop is used. This necessitates a comparatively long exposure—no easy matter when every petal and leaf, emulating the traditional aspen, quivers with the slightest breath of air. Absolute stillness has to be patiently waited for. The common saying, "Not a breath stirred," infers a state of things seldom met with during the day, especially in a Scotch garden. A certain amount of softness in the definition of parts of a group is often an improvement. What should be aimed at is a picture which will express in some degree the tender delicacy of flower petals and their texture. Roses should not be hard and clear cut as if they were shells or moulded in fine porcelain; nor must they err on the other side and lose all feeling of the cool freshness we associate with the touch of them.

Isochromatic plates are much recommended for flower photography, and for some colours they are indispensable, but my own experience is that any good very quick plate will, as a rule, do excellently for open-air work. The difficulty of getting the flowers absolutely still makes a short exposure imperative, and yet it must be a full one, for a harsh under-exposed negative is hopeless. Therefore I prefer a quick plate.

The developer used should be slightly weaker than for landscape work. It is generally safe to use the one the worker is accustomed to, slightly modified to suit the case.

Development carried too far is a great mistake, particularly with studies of white flowers. What is desirable is a clear, good negative, with plenty of soft detail in it, and no fog. Such a one prints clearly, without losing the delicate half-shades of the flowers. Great care should be taken not to expose the plate to too much light in the dark room; even red light should be sparingly used with the quicker makes.

For studies of flowers there is a large choice in the matter of printing processes. They look well in almost any, particularly so in carbon. They have this advantage, that, as the inversion of the image rarely matters, single transfer suits them as well as the longer process. They tell no such tales as do figure studies. An excellent one of a seamstress, seen lately, represented her as sewing diligently with her left hand.

Platinotype, too, gives very good results, either on rough or smooth paper. I find that the best are got by printing, even in summer, from a negative of average density, in the brightest sunshine available.

In winter a good deal can be done to avoid the dull, muddy look which, in spite of all precautions against damp, will often show itself then, by warming everything used in printing. The negative should be held to the fire for a few minutes, and the printing frame laid inside the fender till thoroughly dry. The bottle containing the developer, its cork loosened or removed, may be placed close to the fire while printing is going on. It will then warm up slowly, and be ready when the prints are to be developed. Those suspected of being under-printed should be done first, as the solution soon cools. If porcelain dishes are used, they, too, should be heated by being filled and refilled with hot water. By taking these precautions good prints may be secured in any weather from a fair negative.

The objectionable muddiness to be guarded against seems to spoil photographs of flowers more than any others, for we trust to their delicate gradations of tone to help us to recall the beautiful tender colouring it is as yet beyond our powers to reproduce.

#### LENSES OLD AND NEW.

BEFORE the London and Provincial Photographic Association, on March 9, Mr. A. T. Harris gave a chat on the subject of "Photographic Lenses." It was notorious, he said, that photographic optics, of all branches of study, was most prolific of discussion, in which fact, when casting about for a subject for his paper, he had decided to find refuge, anticipating that a few well-chosen words would be sufficient, by the lively discussion which must ensue, to make up for any lack of something original in what he had to say. The present was, he thought, an excellent time to ask whether the improved lenses of the present day were really worth the large amount which was asked for them when the work of these and the older and cheaper lenses was compared? For himself, he believed that, for many classes of work, the cheaper French and English lenses were excellent instruments, although admittedly not equal to certain exacting conditions. His remarks, however, were directed more towards the amateur, who might be tempted to believe that the newer lenses were absolute essentials to his outfit for what was only work of a general character. To take the statement of claims, as given by lens-makers in their price-lists, there was the inevitable item about the large working aperture of "this, the best lens made," covering such-and-such a plate to the edges at a given aperture. In mentioning these, he did not infer but that it was absolutely correct, but he did wish to discuss whether these advantages were necessities, and whether, taken from the point of view of the general amateur, who has perforce to look at his money before parting with it, any such superiority justified his expenditure of the larger amount. Could it be said, the lecturer inquired, that this large aperture, of which so much was made, was required? In special

cases, yes; but in general cases he thought not. Take the field days of photographic societies as an example. While yet talking about the large working aperture of their lenses, they disregard it altogether in practice. The object of the large aperture is the possibility afforded for rapidity of exposure; but, at the same time, other conditions tend so much to the same end that, for the majority of general work, the smaller stop of the cheaper lens answers all requirements. Another quality urged on behalf of the newer lens was flatness of field. Here, again, in everything but critical work a lens of some curvature of field was rather to be desired, and the same might be said of other excellent qualities claimed for the new lenses, which in every-day practice are rarely brought into requisition. Mr. Harris was recently looking around the walls of the South London Photographic Society's Exhibition, and wondered how many of its pictures were the result of the valuable lens, and how many were secured only by the facilities afforded by the large apertures they allowed. In many cases he found that they were taken with a landscape lens, and, further, that the man who had the valuable instrument has simply stopped it down; and the general opinion was that it was no matter whether it was a valuable lens or not. He considered all this as good argument, as exhibitions must be admitted to attract the best work; the standards of excellence, as it were, were found on exhibition walls. Why, then, if this be so, are these valuable lenses so necessary?

At the conclusion of his remarks a selection of lantern slides was shown with a view to comparing the work of different lenses at their various apertures.

Mr. P. Everitt thought that Mr. Harris's remarks could not fail to appeal to the amateur, and agreed that, for ordinary amateur work and exhibition work of the present pattern, there was no vital necessity for the more expensive kinds of lenses. Indeed, one could obtain results which were quite satisfactory from the pictorial point of view, with a plain spectacle lens, observing the necessary precautions. A sharp picture of considerable angle was possible by stopping down the lens, one that might even be enlarged. A spectacle lens might also be arranged to give the best definition centered on one thing with the rest in diffusion. Such a lens, then, from its price and the many inherent good qualities it possessed, might be taken as perhaps one of the best an amateur could have; but for professional or special work, subjects which were exacting in their conditions, the spectacle lens would break down, and one must perforce have recourse to the more expensive class of instrument. He offered it as sound advice to the professional that he would be wise to possess himself of the best lens he could get. With the largest aperture one could yet get the finest definition with perfect freedom from astigmatism at the same time, and there was a lens on the market at the present time which would fulfil all these conditions. He had shown that it was possible to get a picture of a fast-galloping horse in one five-hundredth of a second, in which even the hair of the animal was defined, proving that with the more expensive lenses one could obtain results which the ordinary rapid rectilinear would not touch. Of course, in comparing the work of the two classes of lenses, it was only right to choose a subject which would call forth the best powers of the lenses employed. However, unless the amateur had the intention of taking interiors, copying, or other critical work, and had to study his pocket, he would say, Do not go in for the expensive lens.

Mr. J. E. Hodd agreed with the lecturer in the main. The extra expense of the best lens was not justified for ordinary work, and the R.R. would embody everything ordinarily required.

Mr. B. Child Bayley so far differed from the reader of the paper as to believe that the new lens, under most circumstances, possessed distinct advantages, excepting, perhaps, for gum-bichromate workers on cocoanut matting. For landscape work he liked to have the best possible lens obtainable. The command over exposure they afforded was sufficient to debar him from the use of anything else. The difference between a really good anastigmat and a rapid rectilinear in this respect was hardly to be realised without experiment, and the power of using for hand-camera work an ordinary plate was an advantage of no mean proportions. He believed that where many people went wrong with these fine lenses was in their ignorance of how to focus. They forget that they are using an instrument of precision, and so often do not get the utmost from the lens. He should plump for the expensive lens; the results were as good, and generally better, than those of older lenses, and, moreover, when selling they fetch a good price.

Mr. Everitt instanced a judgment passed upon a lens by its visual accomplishments alone, and said that one should never estimate by the ground-glass image, especially with the modern anastigmats, the photographic results of which were far better than the visual results.

Mr. H. C. Rapson also testified to the greater fineness of definition of the anastigmats. The finest ground-glass screen he could obtain was too rough until it received a coat of varnish. Another argument in its favour was that great speed of plate was less important, as these lenses with a large aperture gave as good quality as the small aperture of the older lenses with a faster plate, and everybody would concede the advantages held by a slow over a fast plate. Among other advantages mentioned, there was that of convertibility. A half-plate lens could be used as a wide angle on a 12×10, and, stopped down, give very good definition.

Mr. S. H. Fry believed that the amateur was credited with attempting the most difficult feats, and, if for that reason alone, he should have the best of tools, something better than the present-day instrument, rather than a cheap and inferior article.

The discussion was both long and full of interesting points, in addition to the above, the Chairman, Mr. Teape, and Mr. Haddon joining, and in reply Mr. Harris laid stress on the fact that, he was addressing himself particularly to the ordinary amateur, and recapitulated and confirmed the arguments he submitted in his paper.

### PHOTOGRAPHIC MENTORS.

AFTER a long experience of the numerous emulsion formulæ published in the various photographic works and journals, it has occurred to me that the authors of those formulæ can seldom, if ever, try them before publishing them, or the grave errors we find in them would never occur; for, after testing a very large number of those published, I have been unable to find a thoroughly satisfactory and workable one. Probably these failures will be put down to my carelessness and stupidity; possibly it is so, but I am not alone in this respect, and my information says that any one, even without any knowledge of chemistry, can make them.

In gelatine emulsions we find the silver varying from twenty-two and a half grains to the ounce to about seven, and the author of the latter says he sometimes adds *more* water; another advocates alum, and gives such a quantity that a moderately hard gelatine is turned into an insoluble lump; no mention is made of what brand gelatine to use, or, if so, it is often an unsuitable one; the directions in one formula say, "When the gelatine emulsion is mixed, it should be stood upon the kitchen hob, and shaken at intervals during the day"—rather a good (?) thing for the gelatine, and, should it be forgotten, which is very probable, I wonder what the emulsion would be like. In one the silver *must* be added first, in the next it *must* be added last, and the glorious diversity of opinion certainly gives us an "infinite variety," which, if not exactly "charming," prevents emulsion-making from becoming monotonous.

In collodion emulsions we find the haloid and other salts are to be dissolved in an amount of alcohol which will only dissolve about half the amount given unless the alcohol is of the weakest; in another, it is advised to add albumen with the only result of coagulating the albumen; in yet another, the haloid salt is in such quantity that a dense precipitate is formed, no matter how carefully mixed; in one, the organic acid and haloid salt are so unsuited to each other that a heavy white precipitate falls when they are mixed, making the emulsion grainy, which some writers say does not matter much, though personally I have found that a grainy emulsion leaves little nodules and lumps in plates or papers. Glycerine and castor oil are advised to be added to collodion in enormous quantities, making the collodion rotten and useless; one emulsion is advised to be washed, another is left unwashed, one is said to keep well, another will hardly keep at all—not a very good recommendation to start with. Collodio-chloride is said to be best coated upon arrowroot-sized paper, for gelatino-chloride almost any pure paper will do; one says it is quite easy to coat collodion emulsions by hand, but more difficult with gelatine, the next says it is quite easy with gelatine, but more difficult with collodion; this may seem a little puzzling to the average reader, but our mentors evidently do not think so.

The novice is advised to "step in where angels fear to tread," as no knowledge of chemistry is required. When it comes to the coating of plates and papers, our photographic mentors are in their element; plates are quite easy to coat, papers are a little more difficult, but the difficulties can be easily overcome. What a glorious outlook for the amateur with limited purse, who finds his plates and papers a serious financial item. Why should he buy these articles when he has all this useful information, and can so easily make them himself? I can imagine the novice starting with no knowledge of chemistry, ditto of fluid measure, ditto of the metric weights and measures, fluid or otherwise, and possibly a faint knowledge of Apothecaries' weight (the most generally used English chemical weight) learnt at school and mostly forgotten. We will suppose our amateur starts upon a chloride emulsion first, as it is easier than bromide. Assuming that he has managed to get a fairly workable formula in collodion, and can make an emulsion fairly well, he wants to coat paper with it, the first question is, "What kind of paper shall he use, and where shall he get it?" His mentors say arrowroot paper is best, but do not say where it is to be obtained. I am afraid he will experience considerable difficulty in getting it, and, should he be successful, the price will be prohibitive, and, what is more, he will find, when he has coated it, that the paper has a "messy" sunken-in appearance, and the chance of getting a decent print off it is very remote; perhaps he tries to get the baryta paper, as generally used by the manufacturers of these papers, and, unless he happens to know any one in the trade, his chance of getting that is anything but rosy; but, even should he be fortunate enough to do so, he will probably find it quite as dear as the ready-sensitised printing-out paper.

Perhaps he next tries a gelatino-bromide emulsion, and, again, to read these articles, one would think it quite an easy matter, and the lot of

manufacturers of chloride and bromide emulsions a life of "beer and skittles;" but, when we find clever chemists saying that the manufacture of rapid bromide emulsion is one of the most delicate operations in chemistry, we begin to think that perhaps after all there may be some difficulties attached to it, which are greatly accentuated by the fact that very rapid emulsions must be made in almost absolute darkness, and the operator must trust more to memory and touch than sight, and very little idea of the result can be obtained until the plates or paper are coated. It would be rather interesting to see some of the authors of these formulæ at work upon rapid emulsions, and more interesting to see what the result of that work was, also to know if they find it quite so easy as it appears from their writings to be; and, if so, what a grand opportunity for some of the manufacturers if they could secure the services of these gentlemen.

Photographers reading these articles will naturally think that the only reason manufacturers erect elaborate and expensive machinery is, so that they can turn the materials out cheaply. Undoubtedly this is partly the case, at any rate, but, up to now, my experiments with paper have only convinced me that nearly all the ideas for coating paper suggested in these articles are useless, and it is only by using elaborate and expensive machinery that paper which is to be of any use can be turned out at all, quite apart from the question of economy.

Let us presume we are going to make a collodio-chloride or collodio-bromide emulsion. When we have made the emulsion, it is to be poured over plates or paper until they are covered, and the superfluous emulsion is to be drained back into the vessel. This is all right in its way, but where is the ether going to in the process? I have generally found that, by the time the second or third plate or piece of paper is coated, the emulsion is too thick to be of any use, besides which, in the case of paper more particularly, at the corner where the emulsion is poured off, the film is much thicker than elsewhere. I am aware that this kind of coating is done in wet-plate photography, but the plain salted collodion used in that process is very much thinner than an emulsion can be made to be of any use. This operation is fairly easy for paper (after some practice) with collodion where the solvents of the collodion have little or no effect upon the paper; but, when it comes to coating paper with a gelatine emulsion, troubles begin, for, unless the paper is held firmly down in some way, directly the emulsion is poured on, it begins to cockle, and the emulsion is left in a series of little pools.

Sometimes we are recommended to lay the paper upon the emulsion in a flat dish, after the manner of albumenised paper; this might answer, although I doubt it, as I cannot see how the emulsion can set upon the paper sufficiently quickly to form anything like a coating; but, even supposing it should answer, it is much too wasteful to be serviceable, as there must always be more than sufficient emulsion to well cover the bottom of the dish, and, when it comes to coating sheets 12×10 and upwards, this would mean a loss of several ounces of emulsion. Plates can be coated with gelatine emulsions fairly easy, as, of course, the water in the emulsion has no effect upon the glass support, and, being a flat surface, if care is used, a sufficient thickness of film can be obtained.

Very seldom is any remark made about the effect of the various haloid salts recommended for chloride emulsions, nor is it often stated that every haloid salt of each different metal gives a varying result in tone by some curious, and at present unexplained, reasons.

I have found that every brand of gelatine gives a different result in the tone of papers, and sometimes different batches of the same brand will give a slightly varying tone, but I have never found this mentioned in any work upon the subject or in any formulæ, and I contend that it should be mentioned, as the gelatine exercises a very curious and marked effect upon the printing paper, whether bromide or chloride. Collodion is practically inert, and, should it make any difference in the colour, which is very seldom, the variation is too slight to be appreciated.

I have no wish to discourage any one from experimenting in emulsion work by the above remarks—very much the reverse, as I am sure that every one who takes up photography must largely benefit by a knowledge of the scientific part of the subject, for undoubtedly it will help them out of many difficulties, but I would advise the beginner in the words of the cynic to "believe nothing he hears, and only half of what he sees" in photography, and not to expect that, when he once gets over the difficulty of making an emulsion fairly well, all the rest is plain sailing, or he will turn up experimental photography in disgust, for any one must be prepared for a series of failures at the commencement, however careful he may be, though he should not give up hope of succeeding.

My idea is that for a workable formula in a gelatine emulsion the particular brand of gelatine to be used should be mentioned, together with the temperature at which plates or papers are to be coated. I have seen in some formulæ that the emulsion should be at a temperature of 130° F. for coating, but cannot imagine what sort of film would be obtained, as I do not know any gelatine which requires anything like such a temperature to keep it fluid. In a collodion emulsion the specific gravity of the ether and alcohol should be given, so that there shall be no doubt as to how the collodion will work, and also that the amount of salts mentioned should dissolve in the quantity of alcohol given. Of course, an experienced hand can get over these difficulties easily enough, but these formulæ are supposed to be written for novices, and, although I am afraid that the mere mention of the specific gravity of the ether and

alcohol would be of little use to the average novice, still it is the only standard one can give.

I would advise any one taking up experimental photography to get a knowledge (even if only a slight one) of chemistry if possible before starting, as it will greatly help him in his experiments, for, although we are told that no knowledge of chemistry is required, even a little knowledge is very useful, and helps one over innumerable difficulties, and, as far as my experience goes, if success is looked for, it is absolutely necessary. Any one could perhaps do without this knowledge if the various formulæ could be depended upon, but they cannot, so I advise the novice to be prepared.

I am quite aware that there must always be a certain amount of diversity of opinion about emulsions, as photographers' tastes differ so widely, but there ought not to be the wide divergence in these formulæ, and cannot be if anything satisfactory is to be obtained. A method adopted very largely of late is to make stock solutions of the various ingredients required, and then take so many parts from each; the only reason for this seems to be to make the formula as unintelligible as possible. If the stock solutions were of equal or proportionate strengths, and proportionate parts were taken, one could understand it; but the stock solutions are almost invariably unequal, and the parts to be taken still more so in proportion, so that, should you wish to get some idea of the proportion that one part bears to another, you must be prepared to go into long columns of decimals. There may be a reason for this system of working, and that a utilitarian one, but I candidly confess that I cannot see it, nor have I met any one who can.

It is necessary that these formulæ should be published, and a good thing for photography that they are, as they very often lead up to fresh discoveries, but surely a little more care might be exercised by the authors before publishing them.

The only thoroughly workable formulæ seem to be those in the hands of the manufacturers, and we can quite understand that they are likely to jealously guard these very valuable trade secrets from the most remote chance of discovery, seeing the large expenditure of time, trouble, money, and patience required to bring them to a state of perfection.

C. T. SUTTON.

### THE SCIENCE OF PHOTOGRAPHY.

The science of photography is so common a phrase that we are apt to conclude that the elements of a new science have been constructed. This conclusion rests on but very little solid material, and, what is more, no serious effort to reduce photographic phenomena to a scientific system has yet been made. Year by year investigators are recording experiments, well-established facts accumulate, and our libraries are fast becoming a chaotic mass of isolated items, fragments of researches, difficult of access, and of no utility, serving only as a striking monument of human industry and curiosity.

To this accumulation of material photography must, for some years, be liable, for, unlike the older sciences, it was not preceded in earlier civilisations by a long course of speculative thought, but leaped at a bound into the experimental arena; its theory and first principles were not discussed previous to the existence of the material for testing their validity. Photography has thus passed through no speculative career, and, until it does so, no first principles can be accurately defined, nor can its phenomena be classified and arranged as becomes a true science.

Speculation proceeds by means of hypothesis and theory, these being the silken threads which alone can guide the mind through a maze of data, to allowing a subject to be grasped in all its complications and as an organic whole. Without a bold and sweeping generalisation to support them, the most orderly array of tabulated items must remain meaningless and beyond the powers of the mind to readily command. A clue of this nature is therefore a practical necessity if the results of experiment are to be properly utilised. Some modern men of science do not recognise this need, being dominated by the belief in the all-sufficiency of experiment, and satisfied merely to add fact to fact, looking upon hypothesis and theory as imagination, a pernicious faculty to employ in the domain of science.

To an extent this censure is merited, imagination, if uncontrolled by evidence, forming the most grotesque and extravagant theories. Rightly used, however, it has entered largely into the most brilliant discoveries that modern science has achieved.

These two opposed views of scientific method happen to be well illustrated in the photographic work of Abney on one side and Hurter & Driffield on the other. Abney is content with exact, patient, elaborate tabulation of experiment, showing a studious care not to allow speculation to intrude, leaving the facts to speak for themselves—a fact which they generally fail to perform, because the mind that conceived the experiments alone knows the language by which they can be interpreted. With Hurter & Driffield we have the same careful record of evidence, but with the distinction that each observation falls under some theory or hypothesis, the imagination being freely used to suggest new lines of experiment, connect isolated data, and to find in the hypothesis or theory the law which governs the effects under examination. A study of the labours of these photographic experimentalists is in itself, apart from the information acquired, an education in scientific method.

Although Abney has always mistrusted theory—a mistrust not shared by Robert Hunt, who attempted to associate science with poetry—it can hardly be disputed that a large part of his services to photography are the outcome of an advocacy of the silver sub-bromide theory—a striking example of how fruitful the pursuit of a theory may become. From Abney's attitude towards theory it has resulted that in his own special province he missed several important discoveries which Hurter & Driffield arrived at by a more liberal use of hypothesis. This very power of theorising has been urged as a defect in their labours, yet it is undoubtedly the source of their strength, and by its aid they were enabled to advance the cause of photographic science.

From hypothesis the test of experiment determines a theory, from a tested theory the law of phenomenon emerges. A law so founded would become a first principle of a real science of photography.

By a photographic science is thus meant the laws of photographic phenomena, a notion quite distinct from what is implied in the common phrases "photographic optics" and "photographic chemistry." Optics and chemistry being themselves sciences, there cannot be a "photographic optics" or "photographic chemistry." This confusion in classification has led to the growth of a bad system of giving instruction in photography. At schools it is usual to treat of the optics of photographic lenses and the chemistry of photographic processes as independent sciences, disconnected from general optics and chemistry. Such a system gives rise to the most perverted ideas in the student's mind, preventing a right understanding of the optical and chemical laws under discussion.

Relegating optics and chemistry involved in photographic operations to their logical position, we come to the actual science of photography. This in its simplest form is resolved into actinometry and development; that is, the laws of the formation of primary images by the agency of light on sensitive compounds and the laws of the production from primary images of secondary images by the process of development.

In the first branch we already possess a well-marked principle, which rises to the status of a scientific law, being axiomatic and basic. Yet even this generalisation has never been cast into a form of words commonly accepted. Abney states it as follows: "The effective exposure is proportional to the intensity of the light multiplied by the time of action." Putting this in other words, "Equal amounts of photographic action result when the product of time of acting and intensity of light are equal."

Here it is asserted that under all circumstances, and upon any sensitive surface, an exposure to a given luminosity for ten seconds will be equivalent to one second's exposure to a luminosity ten times as intense, and similarly for all other intensities and times of action. This is a far-reaching statement, and in the main it holds good when brought to the test of experiment. Abney, however, has shown that it is not strictly followed when a series of exposures of less than a second to a strong light are matched against a long exposure to a weaker light; for example, one-tenth of a second at a foot from a candle, and ten seconds at ten feet from the same candle, under such conditions the short exposure giving a deficient density. Apparently here is a breakdown in the general law, though probably it is merely an experimental error inherent in these conditions, the law being obscured by the plate-speed factor.

The laws of photography must always be of this approximate character, but, considering that such an exact science as mathematics suffers like defects, it need cause no alarm. With our science all we can hope to achieve is to formulate its principles as theory, not demanding their strict occurrence in practice, except within given limits from a mean.

The foregoing law may thus be taken as the foundation of exposure, for, if its truth is seriously questioned, it would reduce all photographic action to a state of confusion, introducing disorder into what now appears regular and orderly.

This first axiom establishing the laws of actinometry as at present laid down came to a sudden end, since, amongst all the numerous recorded investigations, no other generalisation has yet been put forward which can be said to rise to the dignity of a first principle, proving how very little we have advanced towards a science of photography, and how boundless is the unexplored region waiting for a really searching intellect to there exercise its powers.

Turning to the second half of our science, we find in the researches of Hurter & Driffield a second generalisation which can be said to possess the features of a scientific law, this being their fundamental theory of constant density ratios, meaning that the ratio of gradation is an attribute of exposure, unalterable by methods or modifications in development. This second law, being a comparatively modern discovery, may in course of time undergo some change; but its essential truth can scarcely be disputed. The law once grasped, it is immediately seen how greatly it disturbs older notions, since it follows, as a consequence, that exposure, and not development, is the chief controlling element in the production of what is called a correct negative.

Briefly put, the law asserts that secondary or developed images are proportional to primary or latent images, an assertion that seems entirely reasonable and in accord with observed facts.

With this law, as with all laws, by imposing abnormal conditions, variations that appear to contradict its accuracy can be produced; in

reality these variations being simply fluctuations on either side of a mean. Once accept the law of constant density ratios, and these same fluctuations are brought under the rule of law, and their limits determined, whilst, on the contrary assumption of movable density ratios, they still remain without rational cause.

Comparing the two laws above enunciated, it is at once apparent how well they agree, both between themselves, and with the wider laws which govern matter and energy, under all its forms. Suppose them different, and we shall have to account for a surplus of energy created from nothing; as they stand, they are in entire agreement with the universal principle of the conservation of energy, since they assume that the final effect is no greater than the initial cause.

The effects of a one candle-metre second of energy remain a one candle-metre second throughout, being always one-tenth less than a ten candle-metre second of energy; in no event does the former become half or one and a half, and the latter eight, fifteen, or twenty candle-metre seconds in effect.

The mutual support thus traced gives an insight into what a science of photography might become, and is evidence that its phenomena follow regular laws that admit of classification and systematic arrangement.

A third principle which must become an axiom in photography is the law of the energy of a developer, and this generalisation will probably be the next step in advance, because, with the multiplication of developing agents, the practical man is thrusting a demand for such a principle to the front. It is, in fact, an urgent need in order to simplify the daily routine of the dark room.

The above three laws are all that remain out of thirty-six propositions written down several years ago as possible axioms. Month by month first one and then another has been slain without hesitation; the survivors are few, but, cut and thrust as I may, they remain alive with a persistency that argues the possession of the vital spark of truth.

JOHN A. RANDALL.

### THE CHEMIST AS PHOTOGRAPHIC DEALER.

BY A CHEMIST.

THE chemist finds the profits in many once highly remunerative directions becoming less and less. Patent medicines, toilet requisites, and so on—once well worth attention—have, from a variety of causes, slipped in a great measure out of his hands, or, what comes to much the same thing, they have been grasped at by so many competitive other hands as to make their selling a very different thing to what it once was. Even in his more special field, grocers sell drugs, drapers scents, and stores dispense prescriptions, at far less comforting prices than he had got to regard as legitimately and particularly his. The natural result is, that he has to turn to fresh directions in the effort of replacing vanished, or supplementing vanishing, profits in the more orthodox grooves. One of these new departures is dealing in photographic articles. Now, on the face of it, the chemist should make a very suitable man at this; his shop is admirably suited to the storage and display of photographic goods, he is himself accustomed to handle delicate and fragile articles, and his familiarity with the weighing of chemicals, and turning them into solutions of definite strengths, to say nothing of the closer knowledge he would have of the properties of active ingredients, ought to stand him in good stead when similarly applied in what pertains to photography. Again, the optical knowledge, and mechanical aptitude necessary, one would naturally expect to be present, or readily acquired at need, from his general scientific training. But theoretical probabilities, from some reason or other, are apt to break down when it comes to practice. Clergymen's sons are rarely held up as shining examples, stockbrokers conclude important money dealings with lead-pencil scribbles in small note books, doctors are careless liveries, madmen less dangerous with unlocked than locked doors, and, finally, to our particular point, chemists do not make good photographic dealers.

Speaking broadly, the whole traditions of a chemist's trade go against the accepted formula for success, if by that be meant a banker's balance on the right side, as understood nowadays. The leading businesses of to-day owe their position to the consistent application of the rule of small profits and large returns; the chemist, on the other hand, has been trained to believe in large profits and small returns. This anomalous position is mainly due to the mixture of profession and trade in his work. Where an element of the former enters, such as in the special knowledge needed and care exercised in the proper mixing of various strong items in a medicine, he is certainly entitled like any other professional man to rank, pay, and profit on the higher professional scale; where this is not needed, he is tradesman pure and simple. As he has, however, much about the same make up in the way of human nature as any other man, it is very natural that the professional wing should be extended to cover as much as possible, and high charges shelter under its shadow when they should not. Applying this in the photographic direction, the chemist is not genially prepared like his more up-to-date competitor to sell with a low enough margin of profit; a camera is held to have something of additional value if figuring for sale in his shop, and far too much is charged for the necessary chemicals. The result is that he suffers, now that people have found out that there is no particular "divinity hedging in"

his shop, excepting only in the sale of poisons. A good deal of grievance and friction there is in this poisons question; but it is one that could very easily be settled by the exercise of a little common sense even under the existing order of things. Were the chemist wise in his generation, he would certainly, with this trump card of being the exclusive legal seller of poisons, in hand, not act as he generally does in charging top prices for what can only be obtained from him, but reduce them to the lowest possible figure, and take full advantage of the very material gain of having once got a customer into the shop, in introducing other and ampler business; but at fair trade prices, and not bastard professional ones, for, apart from all other considerations, it is useless standing out for the latter against the general cheapening tendency of an educated age. The same reasonable holding to a low profit ought also to give him an advantage in putting up the various solutions for amateurs; but even the amateur is not going to recognise any particular claim for doing so, beyond a fair profit upon the ingredients and bottle, and a slight charge for the trouble. In plain English he must shed the idea that a special training in one direction makes him superior to his fellows when off his own ground. It is rather unfortunate that the slightness of that training goes rather against doing this readily, begetting instead a tendency towards quackish pretension. Must it not be admitted that the gravity of his demeanour, together with the archaic air of his surroundings, give him rather a dodo air, a something that may have had eminently useful purpose at some past time, but now to all common-sense judgment unfitted for the present commercial struggle? All goes against smart photographic business, and the desirable capacity of being able to grasp any new idea and departure in a field markedly rich in them.

Another drawback he suffers from is that, owing to the personal attention needed by his duties and the long hours he has to be at them, there is not the opportunity for acquiring, in pleasant little ramblings and social intercourse with photographers, a practical knowledge of the work. How this handicaps him can be readily judged by the cheap rubbish so frequently shown in his window; and in selling it must surely be more markedly still to his disadvantage, for what can equal in effectiveness the discussion of methods of practical working with a customer?

The same drawback, of long hours and close attention to business, must be held accountable—"though cry this not too loud in the streets of Ascalon"—for the suggestion of sourness of temper, and impatience of contradiction, somewhat noticeable in chemists as a class. This tells unfavourably in the oftentimes tedious, always lengthy, process of persuading a man to part with his money for a camera, or what not. The *ex-cathedra* air of the recommendation that carries off, with remarkable promptness, the sale of a box of liver pills, or bottle of cough mixture, where all the knowledge is on one side and a readiness to try anything for the relief of pain on the other, is decidedly not the best one in selling a photographic article to a customer, with his own fully developed ideas respecting his hobby very much to the front.

I hasten to add that there are many exceptions, especially in the younger ranks, and, if these take up photographic dealing upon the modern lines roughly indicated, they could undoubtedly make a good thing of it, both for themselves and their customers. The Pharmaceutical Society is honourably anxious to lift the professional status of the chemist, and is doing its best to that end, by stiffening examination and aiming at a closer monopoly in the sale of poisons. Whether it can do so, and still make him a business success, is very doubtful. The tendency of the day is against legal monopoly; and, proof of the pudding being in the eating, nine-tenths of the men, after passing their qualifying examination, soon find, in the struggle for bread and cheese, that it pays better to sink the professional side, and fight with such recognised trade weapons as attractive window displays, competitive prices, and free mixing upon equal terms with their fellows. And, as this is a natural evolution occasioned by the force of circumstances, it must have about it more of permanence than any, though admittedly higher, artificial, academic effort of the few in a contrary direction, the natural comforting delusion being, that the chemist will go on improving as a dealer in things photographic.

### ADOPTION OF THE METRIC WEIGHTS AND MEASURES.

ON March 22, the President of the Board of Trade will receive a deputation of representatives from the Decimal Association, Chambers of Commerce, Educational Institutions, and Trades' Unions who will urge upon the Government the compulsory adoption of the metric weights and measures after a period of two years to be allowed for preparing for the change, January 1, 1901, having been suggested as a suitable date for the introduction of the new system.

The agitation for this reform has received a considerable stimulus of late through the numerous and emphatic reports of British Consuls, residing in metric-using countries, who are practically unanimous in stating that serious damage is done to our foreign trade, because of our obstinacy in clinging to our most absurd weights and measures when quoting for goods or giving specifications for material where the metric system prevails.

It is not too much to say that every thoughtful person connected with education in Great Britain would hail the change with enthusiasm, because our children would be relieved from learning or trying to learn

our complicated tables of weights and measures, and the exercise of compound arithmetic would gradually disappear. The time so saved could be used to so much better advantage in other directions, and in these days of keen competition we cannot afford to neglect any such opportunity for economy of time.

The movement originated with Chambers of Commerce, who have for a long time agitated for the introduction of the metric system.

The National Union of Teachers has always strongly advocated this change, and, on more than one occasion, resolutions to that effect have been passed at their annual meetings.

The Trades' Unionists, too, have made a close study of the subject, and are warm supporters of the reform. The Trades' Councils of Manchester and Glasgow, last month, passed resolutions in favour of the objects of the Decimal Association. Representatives from the Trades' Councils of London, Edinburgh, Manchester, Glasgow, Sheffield, Leicester, Bristol, and other important centres, have promised to attend the deputation on March 22, and give the weight of their influence in favour of the objects of the Decimal Association. Roughly speaking, they represent 2,000,000 workers, and their petition should not be disregarded.

### CRYSTOLEUM.

At the meeting of the Leeds Camera Club, on Wednesday evening, March 8, "Crystoleum, with practical demonstrations," was dealt with by Mr. J. Skilbeck. This process, said the lecturer, depended upon the placing of a silver print in optical contact with a piece of prepared glass, the paper support of the print being then somewhat reduced, cleared, and the subject treated with oil colours from the back of the print, or on another piece of glass placed behind it, the ultimate results being most pleasing. There was no great difficulty in the process if the fundamental principles were clearly understood. The print, preferably on albumen paper, should not be too dense in the deepest shadows, and should show all the details quite clearly. Perhaps the most difficult matter they had to contend with was the placing of the print on the glass; and Mr. Skilbeck demonstrated the method he adopted, whereby it became one of extreme simplicity, avoiding all air bells, "slug marks," and, above all, the thorough extraction of the adhesive used. Following on to the clearing of the print, the lecturer showed the different methods they could adopt, pointing out the particular properties of each, and what they should avoid doing in the manipulation. In the one known as the "medium" process it became absolutely necessary to use a preservative coating after the medium had done its work, otherwise, sooner or later, the print became covered with opaque spots; and this preservative must also be mixed with the colours used when being applied to the print. In the "wax" method of clearing, which he also showed, the lecturer said it only became necessary to place the print when mounted and its excess of paper removed into a bath of hot paraffin wax, at a temperature of not over 180° Fahr., allowing it to remain about an hour; and, if when cool any grey markings appeared, they were readily removed by rubbing the print with almost any kind of oil and warming gently in front of the fire. If this method is adopted, poppy oil would be mixed with the paints in the colouring, no preservative being required. In the painting, Mr. Skilbeck advocated the use of two glasses, the principal colouring being on the second; and by this method a softness and quality were obtained quite impossible if all the colouring was on the one glass.

## Our Editorial Table.

DEVELOPER FOR BARNET PLATINO-MATT BROMIDE PAPER.

Elliott & Son, Park-road, Barnet.

Messrs. Elliott have sent us for trial a bottle of a one-solution developer which is recommended for use with their platino-matt bromide paper. The developer keeps well, works cleanly, and can be used for several prints—advantages which practical trial confirms. Mr. Hubert Elliott tells us that he personally uses the developer, the formula for which is as follows:—

Metal .....	200 grains.
Hydroquinone .....	150 "
Sodium sulphite .....	6 ounces.
Potassium bromide .....	50 grains.
" carbonate .....	2 ounces.
Water .....	80 "

Dissolve the metal first and the other ingredients in the order named. One-solution developers will always be highly favoured by large numbers of photographers, and users of the Barnet bromide paper will appreciate the convenience and suitability of the above-mentioned solution for its specific purpose. The Barnet bromide paper continues to manifest the excellent qualities which early won it favourable recognition. Rich blacks, delicate half-tones, and pure whites are looked for in this paper as a matter of course; and therefore it can scarcely be wondered that the paper is meeting with wide popularity at home and abroad.

### THE LOTHIAN STEREOSCOPE.

A. H. Baird, 37 and 39, Lothian-street, Edinburgh.

Two or three distinctive features mark out the Lothian stereoscope as one of great value in practical use. These are apparent from a glance at the illustration. The centres of the oculars are adjustable by a simultaneous movement; the eyes may be placed quite close to the lenses, which are easily removable when it is desired to substitute others of different foci, and the flexible division or septum allows of the instrument

comfortably fitting to the face. The Lothian stereoscope is light and portable and possesses the further advantage that the carrying tubes are made detachable, so that the instrument may be used for examining stereoscopic prints in albums, stereoscopic window transparencies, &c. This is a very great convenience now that stereoscopic book illustration is on the increase. We can thoroughly recommend the Lothian stereoscope.

We have received from Messrs. James Willing, jun., Limited, of 125, Strand, W.C., the twenty-sixth annual issue of *Willing's Press Guide*. This useful book not only gives local and general lists of all the periodical publications issued in Great Britain, but sections are devoted to the Colonial, American, and Continental press. It is an invaluable work of reference to those whom business obliges to have dealings with the press in various parts of the world.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, March 22, at eight o'clock. Mr. E. J. Wall, on the "Stereoscope," &c.

ROYAL PHOTOGRAPHIC SOCIETY.—Photo-mechanical Meeting, Tuesday, March 21, at 12, Hanover-square, at eight p.m. "Automatic Adjustment of the Half-tone Screen," by W. Gamble.

MESSRS. MCKELLEN, LIMITED, of Manchester, write: "It may interest your readers to know that our Company have taken into their employment Messrs. Kershaw, of Buxton, the original inventors of the Roller-blind Shutter, who are assisting in the production of the McKellen Triple-action Roller-blind Shutter."

To meet the growing demand for Luxia P.O.P., and also with a view to the contemplated production of other varieties of photographic printing papers, Messrs. Berger & Co. have found it necessary to considerably enlarge their factory at Hampstead Heath. The new extension affords an additional 30,000 feet of working floor space, and will be completed in another week. The machinery now being installed in this wing is of the most modern type.

The strength of vision in savages proves to be much less extraordinary than was supposed. Dr. Beheim, on a visit to Johannesburg, has tested the sight of 1858 Kaffirs, Basutos, Hottentots, Zulus, and Bushmen, finding 1509 with normal vision equal to that in Europeans, 257 with stronger sight, and eighty-seven with weaker. Phenomenal vision was shown by a Kaffir girl of fourteen, who perceived objects at sixty feet away as well as a normal white could at twenty feet.

EASTBOURNE PHOTOGRAPHIC SOCIETY.—The Committee announce the following competitions, open to all residents in Eastbourne and the neighbourhood within a radius of twelve miles: Competition No. 1.—Class A. For the best Photograph on Paper, representing "A Sussex Landscape." Prize, 11. 1s., offered by Mr. Alderman Farrcombe. Class B. For the best Set of Four Lantern Slides, same subject. Prize, 11. 1s., offered by Mr. T. R. Beckett. Competition No. 2.—Class A. For the best Photograph on Paper, representing "Woodland Scenery." Prize, the Society's medal. Class B. For the best Set of Four Lantern Slides, same subject. Prize, the Society's medal. In Class A each competitor may send not more than three prints. In Class B each competitor may send one set of slides only. Prints may be of any size or by any process, and should be mounted, but not framed. Entrance fee for non-members, 1s., which will entitle competitors to enter in both classes of each competition or either one thereof. Prints and slides must be delivered to the Secretary, Mr. J. J. Hollway, 11, Hyde-gardens, on or before June 1. Any further particulars can be obtained on application to the Secretary.

THE bookseller, Charles Hirsch, of the Librairie Parisienne, No. 4, Princes-buildings, Coventry-street, W., convicted last session of selling, uttering, and publishing an obscene book in the French language, four improper photographs, and procuring and obtaining for the purposes of sale six indecent books printed in English, was last week placed in the dock for sentence. Mr. Loveland-Loveland passed accumulative sentences totalling nine months' imprisonment. His Lordship refused to grant a case on the point raised by Mr. Mathews that it was impossible to corrupt the liege subjects of her Majesty the Queen by the sale of a book printed in a foreign language.

At the London Sheriff's Court, on the 9th inst., before Under-Sheriff Burchell, an important West-end compensation case, *Ellis versus the Baker-street and Waterloo Railway*, came before a special jury for the assessment of damages. The plaintiff was Mr. Alfred Ellis, photographer, of 20, Upper Baker-street, who claimed from the railway company the sum of 17,859*l.*, of which 10,385*l.* were in respect of four years' profits on his business. Mr. Freeman, Q.C., Mr. Foote, Q.C., and Mr. Neish appeared for the plaintiff, and Mr. Cripps, Q.C., Mr. Lloyd, and Mr. Acland for the defendant company. In opening the case Mr. Freeman said the case was one of very great importance to the plaintiff, who had acquired and worked up a most important connexion as a photographer in the West-end. The Company affected were constructing a line of railway from Baker-street to Waterloo, and for this purpose had to acquire many properties, one of which was the premises of the plaintiff. Mr. Ellis commenced business in 1884, and obtained a lease which did not expire until 1908, at a rental of 130*l.* His position was exceptional, inasmuch as his premises were considerably removed from those of any rival artist, and, by dint of great energy, and by reason of the situation he occupied, he worked up a large West-end connexion. From every point of view Mr. Ellis had suffered considerably, and counsel asked the jury to award him substantial damages, to which he considered himself fairly entitled. Mr. Ellis, in the witness-box, corroborated the opening statement of counsel. A verdict was entered, by consent, for 6600*l.*

**SZCZEPANIK AGAIN.**—Szczepanik occasionally gives interviews to the press at his laboratory, and when Dr. Johannes Horowitz, the Vienna correspondent of the *New York Times*, went to see him a short time ago, he found the young man bubbling over with new ideas, in which the ultra-violet rays played a major part. The inventor took Dr. Horowitz into a room in which two miniature railway trains were approaching each other on the same track. At some distance from each other they suddenly stopped. This was another one of the great inventions added to his *répertoire*, and the inventor explains the effect as follows: When the trains are approaching each other on the same line of rails, the ultra-violet rays of light from the lamps act upon the respective electric apparatus, set automatic brakes in motion, and thus stop the trains whether in daytime or at night. The inventor also thinks that, with the aid of the apparatus he is constructing, he will be able to aim guns with absolute certainty. On the enemy's approach the other army would withdraw, leaving behind baggage wagons and other impedimenta loaded with bombs. The explosives are furnished with a small apparatus, the nature of which he does not divulge. When the enemy reaches the camp, a powerful electric or magnesium lamp will shed a light on the explosive material, and, at the same moment, when a single ray falls upon the apparatus, the bombs will all be exploded. In the same way submarine mines would be fired, and, of course, it would be useless to aim guns. Guns could be directed against the enemy without even measuring the distance. With a rectilinear stop, rays would be sent out which would form a wall of light which could not be penetrated by a bomb provided with the apparatus without its bursting. Instead of the present problems of aiming and measuring with guns, it should be practically, in the future, aiming at a light. These are only a few of the stories which emanate with delightful frequency from the laboratory of this gentleman, who is blest with such a fertile imagination.

## Patent News.

THE following applications for Patents were made between February 27 and March 4, 1899:—

**PRINTING FRAMES.**—No. 4264. "Improvements in Photographic Printing Frames." L. HUDSON.

**NATURAL-COLOUR PHOTOGRAPHY.**—No. 4290. "An Improved Process for the Production of Photographs in Natural Colours upon Paper or other Flexible Support." G. SELLÉ.

**COLOURED PHOTOGRAPHS.**—No. 4601. "Improvements relating to the Production of Coloured Photographs and to Apparatus for Viewing the same." Complete specification. R. W. WOOD.

**FILM-HOLDERS.**—No. 4621. "Improvements in or relating to Cameras, and in Appliances for Holding Films or Plates, with Means for Securing such Films or Plates in Position, and for facilitating the Removal of the Film or Plate-holders." J. N. WRIGHT.

**DEVELOPING PLATES.**—No. 4695. "An Improved Portable Apparatus for Developing and Washing Photographic Plates and the like." J. PUMPHREY.

**CAMERA STAND.**—No. 4696. "An Improved Camera Stand for Attachment to Cycles." J. PUMPHREY.

**PHOTOGRAPHY.**—No. 4802. "Improvements in Photography." T. D. LICHTENSTEIN.

**DEVELOPING AND FIXING.**—No. 4808. "Process for simultaneously Developing and Fixing a latent Photographic Image." Complete specification. L. ELLON.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
20.....	Barnet and District .....	In Northern Latitudes with a Camera. Lewis Medland, F.Z.S.
20.....	Bradford Photo. Society .....	Trade Demonstration with Lantern Slides. Thornton-Pickard Company.
20.....	Camera Club .....	In the Footsteps of Wordsworth. Percy Lund.
20.....	Kingston-on-Thames .....	Social Evening.
20.....	Richmond .....	Lantern Evening: Prize Slides.
21.....	Beverley .....	A Visit to America. H. W. Ward.
21.....	Birmingham Photo. Society ..	Methods of Working. W. Smedley Aston.
21.....	Gospel Oak .....	General Meeting.
21.....	Hackney .....	Prize Slides.
21.....	Ile of Thanet .....	Helps and Aids to Amateurs. G. F. Blower.
21.....	Lewisham .....	The Chemistry of Development and Reduction. A. J. Dickenson, F.I.C., F.C.S.
21.....	Royal Photographic Society ..	Automatic Adjustment of the Half-tone Screen. W. Gamble.
22.....	Croydon Camera Club .....	Ninth Annual Dinner.
22.....	Leeds Camera Club .....	Some Analogies of Light. Mr. Heywood.
22.....	Photographic Club .....	The Spectroscope, &c. E. J. Wall.
23.....	Ashton-under-Lyne .....	Exhibition of Members' Lantern Slides.
23.....	Beverley .....	Demonstration with Hardcastle's Platinum Paper.
23.....	Bolton Mutual Photo. Society ..	Lecture.
23.....	Camera Club .....	Exploration in the Canadian Rockies: a Search for Mount Hooker and Mount Brown. Professor Norman Collie, Ph.D., F.R.S.
23.....	Darwen .....	Lantern slide Making.
23.....	Liverpool Amateur .....	On the Great Ouse. Dr. J. W. Ellis, F.E.S.
23.....	London and Provincial .....	Open Night.
23.....	Woolwich Photo. Society .....	Platinotype. W. H. Dawson.
24.....	Croydon Microscopical .....	Faults and Blemishes in Photographs and their Remedies. E. Dockree.

### ROYAL PHOTOGRAPHIC SOCIETY.

MARCH 14.—Ordinary Meeting.—Mr. Chapman Jones, F.I.C., F.C.S. (Vice-President), in the chair.

#### BUSINESS ITEMS.

The CHAIRMAN announced that the Council had appointed Messrs. A. Mackie, J. A. Sinclair, and H. Snowden Ward as the delegates of the Society to the Affiliation Committee, and also that the following members had been appointed to form the Exhibition Committee in connexion with the forthcoming annual Exhibition: Messrs. R. Child Bayley, W. E. Debenham, T. Fall, Chapman Jones, F. C. Lambert, A. Meckie, J. C. S. Mummery, J. A. Sinclair, and J. B. B. Wellington. It was further announced that Miss Boden, and Messrs. R. Child Bayley, T. Bullen, W. Hargrave Cooper, Goldie, A. H. Marsh, and W. Taylor had been admitted as Fellows of the Society. Fifteen new members were elected, and six candidates for membership were nominated.

#### COLOURS FOR THREE-COLOUR PRINTING.

Captain W. DE W. ABNEY, C.B., D.C.L., F.R.S., &c., read a paper, which he illustrated by many experiments, entitled "Theoretical Considerations in Choosing Colours for Three-colour Printing," a subject which he said he was induced to bring forward because it was uppermost in the mind of the photographic public at the present time, and more especially as a good many workers were following out a "rule-of-thumb" guidance not based upon scientific principles. He commenced by a reference to his recent determination of the colour sensations, now under the consideration of the Royal Society, and said that the colours most nearly approaching to the three sensations were vermilion, to which a little blue was added to take off the yellowness of the scarlet, emerald green, and true ultramarine. This point had a great deal to do with the question of the inks to be employed in trichromatic printing, because, for the attainment of correct rendering, the inks must be absolutely complementary to the colour sensations. It was a curious fact that the only gelatine plate he had met with which would reproduce the spectrum accurately was an ordinary plate unorthochromatized, used with suitable screens; an ordinary plate was not only sensitive to the blue, but also, to a less degree, to the green, and still less to the red, with exposures of approximately 1, 8, and 100. Captain Abney's paper may best be summarised in the words with which he concluded, as follows: "In order to get correct colour printing, you must first of all consult the three sensations, if you want to get the purest prints possible; that is to say, take the colour which is a little below C of the spectrum for the red, take one which is about one-tenth of the distance between E and F of the spectrum for green, and take the blue lithium line as the colour for blue; these are the three colours which answer best of all for triple projection. In order to get the proper printing colours, you must get the very complementaries of these, and, if you want purity, these complementaries must overlap as little as possible, and in any case they must always be separate parts of the spectrum; unless this condition is observed—if one colour overlaps another—you will get muddy prints, and prints which are incorrect in colouring. After looking at a great many prints from various sources, I have come to the conclusion that, as a rule, they are correct in the yellows, wrong in the blue-greens, and wrong in the pinks; the consequence is that the greens are always too blue, and very often the reds are too yellow, for there is not enough blue in the pink, and not enough green in the blue. This remark applies only to transparent inks. It seems to me that the great failure at present in colour printing arises from the use of the wrong-coloured inks. I think the photographer may be left

to take a proper negative; he can do it if he has a mind to and if he uses the proper sensitometer, and I have in a former communication shown how to use a colour sensitometer for making the screen. It only remains for the ink-maker to step in and show what he can do in the way of producing the proper colours. With the colours which I have shown accurate prints may be obtained. Of course, what I have to say is all theoretical, but theory cannot be altogether ignored. If the practical man will imitate these colours—not in aniline dyes, which will fade, but in some colours which will be permanent—he will have conferred a distinct boon upon those photographers who are trying triple printing. The photographer has done his work; it only remains for the ink-manufacturer to do his, and when he has done it I think the day will be near when trichromatic photography will become a bigger success than it is at the present time; but one cannot now examine reproductions of coloured objects without seeing that there is something wrong with them, and I have endeavoured to night to point out the manner in which that error may be removed."

Mr. E. SINGER-SHERPHEARD, by way of emphasising the importance of working according to theory, rather than by "rule-of-thumb," said he had lately made some screens with the aid of Captain Abney's colour-sensitometer and Mr. Cadett's luminosity-measuring apparatus, and with them had secured perfect renderings of landscapes, paintings, and a colour chart, at the first attempts. With regard to inks, the difficulty was to obtain transparent pigment colours to match the absorptions; the theoretical colours could be very nearly matched in aniline inks, but unfortunately these inks had been proved to be very fugitive.

Mr. J. W. LOVIBOND said the subject involved a revival of the old controversy as to what were the primary colours, and he differed from Captain Abney on this point. Until each pigment had its own law of absorption, a law specific to itself, he did not see how a printer could select a pigment which should combine all the advantages necessary to the production of a perfect print. A great deal more light must be thrown upon the subject before any hard-and-fast rule could be laid down for the practical man, who by his work ascertained experimental facts upon which all true theory should be based.

Mr. WARRING showed some slides to illustrate the various mixtures possible with three simple colours.

The CHAIRMAN said it had been stated that, although three colours were very well so far as they went, four, five, or six colours would be better; and he asked Captain Abney's opinion upon that point, and also as to the importance of the colour-sensation curves in connexion with the subject of three-colour work.

Captain ABNEY, in the course of his reply to the brief discussion, said that, as there were only three colour sensations, the fewer the colours used the simpler and more effective would be the process; and no purpose would be served by using more than three. The sensation curves had a very important bearing upon the result, for, to secure bright prints, the colours of the inks must be those most nearly complementary to the true sensation colours.

A hearty vote of thanks was given to Captain Abney for his valuable paper.

#### COMING EVENTS.

March 21, Photo-mechanical Meeting. "Automatic Adjustment of the Half-tone Screen," by Mr. W. Gamble. March 28, Technical Meeting. "Ozotype with Carbon Tissue: a New Method of Pigment Printing," by Mr. T. Manley.

**Cripplegate Photographic Society.**—This Society held its first Lantern Night on Monday, March 6. It is matter for congratulation that the members turned up in full force with their friends, and a very successful meeting was spent, the slides on the whole being above the average. The next meeting is fixed for Monday, April 10, when Mr. A. Horsley Hinton will give his well-known lecture on "Practical Pictorial Photography." Early application is requested for tickets. Admission free, but a few seats will be reserved at 6d. and 3d., obtainable of Mr. Alfred T. Ward, Hon. Secretary, Cripplegate Institute, Golden-lane, E.C.

**Croydon Microscopical and Natural History Club (Photographic Section).**—Friday evening last was devoted to an exhibition of some 160 slides by Mr. A. P. Holes, of the Sutton Photographic Club, comprising views in the Channel Islands, Norfolk Broads, and Lake District. All those who read Mr. Holes's paper on "Lantern-slide Making" were quite prepared for a treat, and they were not at all disappointed, the slides shown being of unusual excellence. The views in the Channel Islands showed the character of the streets, buildings, and habits and customs of the people, besides the conformation of the coast. Those of the Norfolk Broads indicated the nature of the country, the disposition of the water, the reeds growing therein, the method of cutting and carrying them, and the yachts and wharves which abound there. The skies in these slides were a special feature and very beautiful; but perhaps best of all were the slides of the Lake District; the charming views, the clouds, and perspective were much appreciated, and it seems a pity this gentleman's slides should not be seen in London. Mr. Ballock manipulated the lantern.

**Hackney Photographic Society.**—March 7, Annual General Meeting.—The report and balance sheet submitted showed the Society to be in a thoroughly sound and flourishing condition. The result of the election of the new executive was as follows:—*President:* Mr. W. F. Fenton-Jones.—*Council:* Messrs. A. Barker, E. Farmer, C. T. Fleetwood, F. W. Gosling, E. Puttock, W. Rawlings, J. J. Westcott, and L. S. Wilks.—*Curator:* Mr. W. A. Ellington.—*Liaisonist:* Mr. Roland Smith.—*Exhibition Secretary:* Mr. S. C. Stan.—*Treasurer:* Mr. W. L. Barker.—*Hon. Secretary:* Mr. W. Selfe.—*Assistant Secretary:* Mr. A. D. Fort.

**Liverpool Amateur Photographic Association.**—On March 9 a crowded and interesting assembly to hear Dr. C. Thurston Holland lecture on the

#### X RAYS UP TO DATE.

The lecturer first proceeded to explain the nature and working of his valuable apparatus, and then spoke of the various improvements which he had effected

since its discovery. Numerous radiographs, which he has taken in his capacity as a medical officer, were next shown on the screen, and excited the admiration and applause of the audience. Dr. Holland, during his lecture, said that, in his opinion, doctors should not perform operations unless they were aided by the wonderful Röntgen Rays, which, up to the present, had proved of invaluable service to the medical profession.

**Redhill and District Camera Club.**—March 7.—The PRESIDENT (Dr. Dufton, M.A., D.Sc.) gave a *Beginners' Night*. The President began by drawing attention to the advantages of a long-focus camera and compound lens, demonstrating how to partially do away with the trouble of the magnification of objects in the immediate foreground by using a single combination of the lens and racking out the body of the camera. He then touched upon the importance of the correct exposure of the plate, recommending all beginners to use an exposure meter. Remarks on developing the plate and on printing and toning of various papers followed, and a demonstration of printing and developing Velox paper was given. At the close of his lecture, Dr. Dufton exhibited a very ingenious home-made enlarging box. A discussion followed on halation and its possible prevention, the general opinion being that the backing of the plate was of little or no use as a preventive. Mr. WILLIAM BROOKS, of Reigate, said that he did not believe in backing plates; that the surest method of preventing halation was the use of a very thickly coated plate; he also drew attention to the danger of using metol developer, owing to its action upon the skin of the hand and fingers. At the close of the meeting a flashlight photograph of the members was taken by Dr. Dufton.

#### FORTHCOMING EXHIBITIONS.

1899.

March 20–May 13 ... National Trades and Industrial Exhibition, Bingley Hall, Birmingham. Manager, Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.

April 3, 4 ..... Beverley. T. J. Morley, Toll Gavel, Beverley.

„ 12, 13 ..... Plymouth Photographic Society. Hon. Secretary, W. H. Harris, 91, Cobourg-street, Plymouth.

#### Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### WANTED, A CHEAP ROLLABLE FILM.

To the EDITORS.

GENTLEMEN,—Prompted by the letter of "H." in your last, and in reply thereto, there used to be, some years ago, the very thing in the market which "H." yearns for, made by the Eastman Company. I used most successfully a dozen or more forty-eight exposure twelve-inch spools of their paper-stripping film in a roller slide and camera, also bought of the Eastman Company, carrying the whole outfit over hill and dale on a bicycle, when, to my deep chagrin, they rendered the whole thing useless by giving up making the paper-stripping film. I have endeavoured to use the films now made by them and other firms, but twelve inches wide is not procurable, and, more than that, ease of manipulation and quality of negative is far below the paper-stripping film, to mention one virtue only, the absence of halation. Let the Eastman Company renew their output; I should again be a user.—I am, yours, &c.,

W. BARRY.

7 and 8, Park-street, Anlaby-road, Hull, March 7, 1899.

#### ANIMATED PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—I am pleased indeed to see in your last issue that Mr. Friese-Greene's efforts as a pioneer of animated photography are at last acknowledged in print; it will be well if the world's papers copy it and spread it as broadcast as they have done the names of other "inventors" "of this most notable of modern photographic achievements," and also that the Chester meeting of the Photographic Convention was the *locale* where the camera first saw daylight. If the group taken on the steps of Eaton Hall, during a heavy rain, by Watnough Webster, is examined, Mr. Friese-Greene, with the camera in his hand, will be seen stood on the observer's left.—I am, yours, &c.,

W. BARRY.

#### CALCIC CARBIDE.

To the EDITORS.

GENTLEMEN,—Acetylene Gas: "The colour of the residue left in the generator indicating the temperature at which the gas was given off."

In yours of the 3rd inst. (LANTERN SUPPLEMENT), a statement is made "that, if the residue is black, a high temperature has been reached." I much doubt the accuracy of this statement. Large quantities of carbide have passed my observations while making acetylene gas, and I have no doubt that the black colour of the residue is principally due to inferior

carbide. A rather large proportion has given not only black residue, but has remained black and unaltered, as so much coal would have done, subsequent immersion in shallow trays of water failing to produce any change. It is quite easy, on inspection of the so-called carbide of calcium, to pick out the pieces, which only give off a small quantity of gas and leave a black residue.—I am, yours, &c.,  
VEDA.

### STUDIO BUILDING.

To the Editors.

GENTLEMEN,—In view of the inquiries you so often receive with regard to the building of studios, it might possibly interest your readers to know that a few notes on the subject appear (for the first time, I think, in a professional architectural paper) in the just-published volume of *Specification*. (London: Office of the *Architectural Review*, Effingham House, Arundel-street, Strand. 5s.) The notes are entitled "The Design of Photographic Premises," and are by, yours faithfully,

DRINKWATER BUTT, F.R.P.S.

35, Keppel-street, Russell-square, W.C., March 7, 1899.

### FREE PORTRAITURE.

To the Editors.

GENTLEMEN,—You have recently adversely criticised Messrs. Tanqueray and others, of Paris, as to their method of business. May I ask you if it is not analogous to the following copy of a letter sent to ladies previous to Her Majesty's Drawing-room? I may say many other pleas are alternated. "As we are compiling an album containing a series of panel photographs of ladies presented at Her Majesty's Drawing-room, we will thank you for an early sitting, so that yours may be included, for which we make no charge. Proofs will be submitted to you prior to sending the album to Her Majesty."—I am, yours, &c.,  
A PHOTOGRAPHER.

March 7, 1899.

### THE LEEDS CAMERA CLUB AND THE YORKSHIRE PHOTOGRAPHIC UNION.

To the Editors.

GENTLEMEN,—The epitaph to Wren, the architect, in St. Paul's, may be translated, "If you seek my monument, look around."

If you seek the proof of the statement contained in my letter to you of last week with regard to the reasons why the Leeds Camera Club did not join the Yorkshire Union, read *THE BRITISH JOURNAL OF PHOTOGRAPHY* of last week (p. 153—only six pages from Mr. Clough's letter in reply to me), and confirmation of our reasons stares you in the face. I must confess I had not expected this would be so manifest so soon. I had thought that the credulous fifteen subscribers would have had, at least, a run for their money, but evidently, although I hadn't sufficient faith to swallow the promises held out some few weeks ago by Mr. Clough and his self-ordained covenant, still I had a bit too much.

From the report it would seem that the Society's delegates grow impatient for the fulfilment of those allurements—they ask for something practical. Mr. Briggs says the chief one, as I said last week, is "a mathematical absurdity," and he wasn't, for an obvious reason, contradicted. Wakefield threaten to "reconsider their position," and Keighley "strongly support." Mr. Godfrey Bingley of Leeds—reasonable, patient, peace-loving Mr. Bingley—quotes "I shall object." But all that is done is for Mr. Percy Lund to suggest ginger bread rules instead of "cast-iron" ones, and for Mr. Ezra Clough, like Nero fiddling over burning Rome, to write long letters to the papers, and wander down the groves of Bradford, culling such bearded old chestnuts as the one he offered to us in his last letter.

We, in the Leeds Camera Club, congratulate ourselves more, day by day, that we decided as we did. Personally I have publicly expressed my best wishes for the welfare of the Union, but I realise that whilst the time of its promoter and principal official is occupied in the demonstration of the educational art of encyclopædia letter-writing, with allusions to ancient history and mythology, Dalton, Huxley, Darwin, and Clough, Shakespeare and the man in the stocks, its chance of success is being seriously jeopardised.

In the words of the immortal Ducrow, I strongly advise Mr. Ezra Clough to "cut the cackle and get to the 'osses," before he finds the 'osses have got out of hand.—I am, yours, &c.,  
W. J. WARREN.

13, Bedford-street, Leeds, March 11, 1899.

### AN ASSISTANT'S DILEMMA.

To the Editors.

GENTLEMEN,—In reference to memorandum in this day's *BRITISH JOURNAL OF PHOTOGRAPHY* re assistant's dilemma, "W" and "F. S." are certainly not the only assistants who find a difficulty in getting a situation. I am a first-class assistant myself, and have had eight years' experience in every branch of photography, and have written for the past four weeks answering advertisements as operator and manager, &c., for business. I have sent photograph of self and references to several,

but have not had so much as a reply; in fact, I may state I wrote to one of the firms asking for return of specimen photograph, &c.

I have a very solid suspicion that there are a few bogus photographers who advertise and request specimens and photographs of applicants to be sent.

I concur with "A. A." in his letter; it is not a first-class assistant that is required nowadays, but perhaps it would be better to term them dabblers; a first-class assistant gets what I call insulted if he makes an application for a situation in a responsible capacity by the advertiser offering, not only a married man, but others, the handsome amount of from 30s. per week to take sole charge, &c., of a photographic business.

I think that "A. A." in his letter is quite right, and would be glad to be a promoter, with others, for forming an Assistants' Protection Union for obtaining more just treatment.—I am, yours, &c.,  
W. A. KIDD.

520a, Commercial road, Portsmouth, Hants, March 10, 1899.

To the Editors.

GENTLEMEN,—Re the above question, my experience is very much the same as "J. A. H." Now, for the benefit of assistants in general, no specimens of work should be sent in the first instance in answer to an advertisement when only a number is used, nor original references, but a copy of the same, saying salary expected and other full particulars, &c., stating, if application is considered, specimens will be forwarded on condition that they will be returned with the least possible delay. By so doing one would learn who one is dealing with. And I also advise assistants engaging on a month's trial, if there is any doubt, this would be fair on both sides. If assistants in general would act as above, it would benefit both employers and assistants, and dispense with a great deal of annoyance.—I am, yours, &c.,  
A. F.

### OPERATORS AND AGREEMENTS.

To the Editors.

GENTLEMEN,—Being a well-known photographer in Weymouth, in justice to myself I must ask you to kindly state in your next issue that the letter, re "Operators and Agreements," in last Friday's *JOURNAL*, did not refer to me.

I may add that both my assistant operator and retoucher, and young lady assistant, have been with me for over eight years.—I am, yours, &c.,  
C. F. HEWITT.

29, St. Thomas's-street, Weymouth, March 14, 1899.

### SPECIMENS.

To the Editors.

GENTLEMEN,—I read Mr. French's caustic effusion with some amusement, and also with a great deal of disgust. In the first place, the editor of our leading photographic paper is quite capable of managing his own business without instructions from any amateur editors as to what they think he shall or shall not insert in his paper.

Mr. French also fears that the "wording of the advertisement leaves little doubt," &c. I'm glad to hear it; it was made plain enough for even the densest intellect to grasp.

May I ask, however, what Mr. French would do were he situated as I am at present. I have never yet shown a photograph in my cases that was not my own *bonâ-fide* work. Be it known, however, that, as an act of courtesy, I invariably ask for permission to do so before I exhibit a sitter's photograph. A very great many have, however, lately expressed the wish that I should not do so, and, at the moment, I find myself very short of specimens of a certain style which are wanting to complete a fair representation. Can Mr. French suggest any other way out of the difficulty? At the same time, any photographer who places in his show-cases better specimens—bought or otherwise—than his average productions is certainly deserving of the severest criticism; but, as long as his output equals in quality his specimens, I fail to see how it matters in the least where the specimens come from.

I must thank you, Mr. Editor, for your very open-minded view of the subject, and apologising for trespassing so much on your valuable space.—I am, yours, &c.,  
PROFESSIONAL.

To the Editors.

GENTLEMEN,—The letter of Harry French has greatly pleased me, and I believe a great many photographers will also agree with me in appreciating the sentiments he expresses. The opinion that such advertisements are both injurious to photographers and to the public strongly presented itself to me. Passing off other men's work as one's own is a fraud, and calculated to injure the more upright members of the profession.

Your allusion to enlargements and coloured prints does not illustrate the point at issue; these may or may not be the work of the photographer whose window they embellish; if not, he simply implies that he is prepared to supply similar pictures, which he probably does from the

same hands as those supplying the exhibits; but, when "attractive specimens" by other operators are exhibited, the public are led to believe they will be supplied with equally good work at the shop exhibiting them. If, and this is a big if, they receive as good work, not much harm is done, but my experience of beginners and others who show other men's work in their windows is that they do not.

I am constantly hearing, "I went to So-and-So. He has very good pictures in his window, but I did not like what I got from him a bit." And, doubtless, such complaints are within the experience of the majority of photographers. I should like to hear the opinion of others in business in large towns, for in these the system is rampant.

As for men just starting in business, they may do as I did, print from negatives actually taken by themselves before starting business, and supplement them, if necessary, by views and portraits of their friends taken for that purpose.

Hoping you will give this letter a place in THE BRITISH JOURNAL OF PHOTOGRAPHY, I am, yours, &c.,  
W. R. GAIN.  
201, Lake road, Portsmouth.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPH REGISTERED:—

D. Lloyd, photographer, Old Chapel House, Kidwelly, Carmarthenshire.—Photograph of group of rocket-brigade men of Castleown, Isle of Man.

TEILO.—The actual makers we do not know, but the goods are obtainable of Messrs. Marion, Soho-square, W.

S. HANNA.—One of the Kodak or Frena type should suit your requirements. We do not answer questions by post.

R. C. V. LANG.—1. Plates. 2. Grooved tanks suitable for the purpose are obtainable from most dealers. 3. Glycin.

H. BARRETT.—The groups are fair, but there is room for improvement. The portraits show promise, but study in lighting and posing appear to be essential. The vignetting is somewhat crude.

MARYPORT.—We cannot tell you the cost, but it should not be more than a few shillings. Messrs. Penrose & Co., Upper Baker-street, Lloyd-square, would probably undertake the work for you.

J. TAYLOR.—We do not answer questions by post. See the ALMANAC for 1889, in which the processes are described in the course of an article on "Iron Printing." Messrs. Marion, we believe, supply the papers.

S. TALLON.—We do not think the proposed plan would work. The fact that the three pictures are taken from as many points militates against correct registration. You do not say how you would make the exposures.

FINISHING ENLARGEMENTS.—A. M. MATTHEWS says: "I should like to know if there is a book published on finishing enlargements," &c. &c. In reply: There are some useful chapters in Johnson's *Retouching*, published by Marion & Co., Soho-square, W.

A. BAKER (Derby-street, Burton-on-Trent).—1. The greenness shows the presence of copper, which was, doubtless, in the residue. 2. By precipitating the silver and re-fusing it, the copper will be got rid of. 3. Only by the appearance of the contents while in the crucible.

MOUNTANT.—R. S. N. The mounting paste mentioned is a trade preparation, and we are not aware what it contains. Therefore we cannot express any opinion as to the effect it may have, or may not have, on silver prints. It is, however, a convenient mountant to use.

J. H. HOGG.—Mr. H. E. Davis, the Camera Club, Charing Cross-road, W.C., will send you particulars of the Florence Exhibition, but we believe that the time for making entries has expired. As to the "French Exhibition" you refer to, we know nothing. What Exhibition do you mean? We do not reply by post.

MARKED NEGATIVES.—ABBE.—The prints show that the marks on the negatives are caused by emanations from the hinges of the shutter of the dark slides. The only way of avoiding the trouble is to have fresh material, which is inert, put on the hinges. If the plates are only left in the slides for a few hours, in all probability there will be no injury done to them.

ENAMELLING.—F. TYFORD asks: "Will you kindly inform me where I can obtain a detailed account of the method of enamelling photographs? I do not mean simply squeezing a print to a piece of plate glass, but the method wherein collodion and gelatine are used."—In reply, Piquepe's *Enamelling* is a book that should suit your requirements; or you will find two or three processes described in the ALMANAC for 1886.

BOOK ON COLOURING AND MINIATURE PAINTING.—ARTIST says: "I shall be grateful if you will kindly recommend some inexpensive books on colouring and miniature painting."—We are not aware of any works devoted to miniature painting. Some have been published on colouring photographs, but we think they are all now out of print, except, perhaps, one that is published by Newman & Co., Soho-square; that is an inexpensive work.

PRINTING PROCESS.—RED CARBONS says: "I should esteem it a great favour if you could kindly inform me of what make is the enclosed paper, also how worked. I have been trying several papers for red carbons lately, but cannot get such good results as the enclosed."—We cannot say by whom the tissue, on which the enclosed print was made, was manufactured; but the Autotype Company, Messrs. Elliott & Son, and others supply tissue of similar colour. Any of the manuals on the carbon process, such as that published by the Autotype Company, give full working details.

REPRODUCED NEGATIVES.—A. MAKENZIE says: "I have a portrait negative of a clergyman who has just died, and I expect to sell a good number of copies if I can get them out sharp. I have reproduced the negative, but the new ones are all weak and flat, although I have tried several different makes of plates and intensification as well. Can you tell me the reason?"—In all probability, the transparency is at fault. Unless that be vigorous, it will be impossible to get vigorous negatives from it. Secure a strong transparency, and there will be no difficulty in getting strong negatives from that.

MONCKHOVEN'S INTENSIFIER.—AJAX says: "I made the cyanide-silver solution for Monckhoven's Intensifier in accordance with the instructions in the ALMANAC. I got an immense amount of flocculent, whitish-brown precipitate, which will not dissolve. I used distilled water, and I added the silver solution to the cyanide solution. Can you suggest the cause of my failure?"—The solution contains undissolved cyanide of silver. The cyanide of potassium should be added to the silver solution till the cyanide of silver, thrown down, is redissolved. The cyanide should be added to the silver, and not the silver to the cyanide.

CRACKED OIL PAINTINGS.—G. W. says: "Can you inform me the best way to fill in an oil painting on canvas? A customer of mine brought me an oil painting, a large one of a man done on canvas, and it is cracked through the face by something that was put against it when moving furniture, &c. What would be the best method to take out the crack across the face? I have to frame the painting afterwards."—This is the work of a picture-restorer and should not be undertaken by a novice, as he would probably ruin the painting. Doubtless the picture will have to be relined after repairing. Repairing paintings requires the work of experts.

STEREOSCOPIC PORTRAITURE.—W. BIRD writes: "I have an old camera fitted with a pair of quarter-plate portrait lenses, originally used for cartes-de-visite, which I wish to utilise for stereoscopic portraits. By putting the lenses as close together as the flanges will allow, the centres of the glasses are nearly three and a half inches apart. Is that too great a distance, or must I get smaller lenses?"—The distance is too great for portraiture. It should not exceed two and a half inches, or, at most, an eighth of an inch or so more. By cutting a piece off each of the flanges, the lenses can be brought closer together, and probably within the prescribed distance.

SPECTACLES.—RETOUCHER writes: "I find my sight is not so good as it was, probably because I am getting older. I have lately got a pair of spectacles, but I find, after working an hour or two, my eyes get very sore, and water a great deal; indeed, though I can see better, my eyes become more painful with the strain than without the glasses. Can you suggest anything to help me?"—It is very clear that the spectacles you have got do not suit your sight. We should advise you to have your eyes examined by an oculist, who will prescribe suitable glasses. If you cannot afford to visit a specialist, go to one of the Ophthalmic Hospitals—that at Charing Cross, or the one at Moorfields.

FOCUSSED BY SCALE.—S. writes: "I am much interested in your leading article, of March 3, as to 'Focussing by Scale,' but how can the accuracy of the arrangement be tested in the case of most hand cameras, which are either Magazine or Kodak? Any information would be most obliging. As a very old photographer, and a subscriber of some years, I always look forward with interest to the arrival of THE BRITISH JOURNAL OF PHOTOGRAPHY. I began about 1855, with the old collodion wet-plate process. I now use quarter-plate size and enlarge."—The only way of really verifying the scale is to place a piece of ground glass in the place occupied by the plate and then examine the image, at the different distances, with a magnifier.

STUDIO BUILDING.—F. W. G. says: "I shall be extremely obliged to you if you can possibly give me a little information. I wish to build a studio. The light will be S.E. aspect; do you think it would be suitable for portraits? The length of the yard is 19 feet long by 12 feet; would that be suitable for a studio? also, how much top light and side light I should require, and what angle? Which side would be the best to light from, the left or right side, with the light S.E.?"—The aspect will do very well, but nineteen feet will be very short for a studio for portraiture, as it will necessitate the use of very short-focus lenses. We should say, with a S.E. aspect, arrange to light the sitter on either side, as occasion may require—i.e., work both ends. Have a good slope to the roof.

COPYRIGHT QUERY.—S. writes: "A year or two ago I took a portrait of a well-known man in our place as an ordinary sitter. He has just died, and the family have taken one of my photographs to another photographer to enlarge, and, I am told, given him permission to copy the enlargement when done and sell copies of it, which is very unfair to me, as the gentleman would not allow me to sell his portraits. The family have also refused me permission to do so. Now, cannot I make the portrait copyright and prevent this injustice?"—No, you have no copyright in the portrait, and the family can do as they like in the matter. As you were paid for taking the portrait, we fail to see that there is any injustice. It is, however, disappointing to you not having the commission.

## EX CATHEDRÂ.

Will our readers and correspondents kindly note that, as Good Friday falls next week, THE BRITISH JOURNAL OF PHOTOGRAPHY will go to press one day earlier than usual? Communications intended for the issue of March 31 should therefore reach us by the first post on Tuesday morning, March 28.

\* \* \*

LAST year Mr. F. E. Ives delivered, at the Bolt-court Technical School, a series of four lectures on the theory and practice of half-tone etching. These lectures, which are exceedingly valuable and exhaustive, have been reproduced in the January number of the *London Technical Education Gazette*. This is published by Messrs. P. S. King & Son, 2 and 4, Great Smith-street, Westminster, price twopence, and we recommend every one interested in half-tone work to procure a copy of the particular number of the *Gazette* mentioned. The lectures are so full of sound information that they should be permanently at hand for reference. In connexion with the Bolt-court School, the *Gazette* points out that in the Elementary Day-

school Code there is a clause permitting children to visit institutions of educational value, such visits to count as school attendances.

\* \* \*

THE *Gazette* adds that the Technical Education Board considers that, under this provision of the Code, much can be done to interest school children in the various mechanical trades and artistic crafts of the present day by arranging for visits to be paid to educational institutions where instruction in such trades and crafts is given. The photo-process trade appears to adapt itself very well for this purpose, as the different processes involved in the trade are of considerable interest and variety and lend themselves readily to practical demonstrations. It is proposed, therefore, to offer opportunities at the Bolt-court Technical School, 6, Fleet-street, E.C., for demonstrations to be given to selected children from public elementary schools, with the view of interesting them in the photo-process and kindred industries. Headmasters of public elementary schools for boys, whether Board or Voluntary schools, are invited to apply to the Board for permission to be given to a selected number of their pupils to visit the Bolt-court School.

\* \* \*

THE principal conditions under which such visits will be arranged are the following:—(a) The older pupils of the school are in all cases to be selected, preference being given to pupils of thirteen or fourteen years of age. (b) Not more than six pupils can visit the school at any one time, as the rooms in which the work is carried on are too small to enable a greater number to be properly accommodated. (c) The pupils must be under the charge of a teacher, who will be responsible for their good conduct. (d) Application should be made to the Secretary of the Board by the headmaster. It is proposed that three visits should be arranged in consecutive weeks, if possible, on the subject, "The Making of a Process Block for Printing," at the following times:—*First visit*: Negative-making—Wednesdays, 10.30. *Second visit*: Preparation of resist for line and half-tone etching; specimen of half-tone etching—Thursdays, 10.30. *Third visit*: Etching of plate prepared in previous visit—Thursdays, 10.30. A fourth visit might, if wished, be arranged, when the subject of "Preparation of Lithographic Transfers" would be dealt with. Friday morning would be the most convenient for this last subject. Headmasters who

desire further information, or who wish to make application to the Board, are asked to communicate with the Board's Secretary at an early date. We have great pleasure in giving publicity to the details of the proposed experiment, which we hope will be carried out, and be of value in interesting young people in photography at an age when the awakening of their regard in such matters is best calculated to prove of permanent benefit.

\* \* \*

Messrs. UNDERWOOD & UNDERWOOD, of 26, Red Lion-square, W.C., whose stereoscopic photographs have during the past few years become very widely known, are making a departure which will have the effect, it may be conjectured, of increasing the growing interest in stereoscopic photography which the public is manifesting. Acting on the hint of that enthusiastic stereographer, the late Dr. Oliver Wendell Holmes, whose proposition was for the creation of a comprehensive and systematic stereographic library, Messrs. Underwood are now classifying their stereoscopic slides into sets of travel. They offer a number of these sets for sale. The scenes are arranged and numbered consecutively, and carry those who view them through the stereoscope from one place to another in the same order that a tourist visits them.

\* \* \*

A REVOLVING cabinet is supplied containing fourteen series, embracing Japan, Egypt, Palestine, Greece, Italy, Russia, Austria, Germany, Switzerland, France, Great Britain, Scandinavia, United States, and Canada. These are accompanied by stereoscopes, and, in some cases, descriptive books. The sets range, in number of stereographs, from 60 to 120. We wish this excellent idea success. Moreover, we trust that Messrs. Underwood's undoubted enterprise will not stop short at paper slides, but that, as time goes on, they will decide to take up the preparation of stereoscopic transparencies, than which, when they are properly made, nothing more beautiful can be produced by photography.

\* \* \*

THE American Photographic Convention takes place at Celoron in July next, and the Treasurer is already at work in the endeavour to induce a large attendance of his brethren. He appeals to them by the media of several of our American contemporaries; and we have thought that the terms of the enthusiastic official's proclamation might have some interest for our professional readers, who, we are sure, will agree that the sentiments he utters do him credit: "I would respectfully call attention to our next Annual Convention to be held at Celoron from July 17 to July 22 inclusive. The executive board having held session and passed upon the many difficult problems arising, to the best of their judgment with equal fairness to all, call upon you for your indorsement, your exhibits, and, above all, your attendance to assist in making this our 19th Annual Convention a grand one. Don't sit in your studio feeling satisfied with your efforts, but come out and join us and spend a week at one of the most beautiful spots in America, studying the exhibits gathered from all sections of the country and exchanging ideas with the many new acquaintances you will make. You will find them the most progressive, energetic, and most social set of gentlemen you have ever met. Let your appointments await your return, and, when with us, lend us your aid in preparing for an ideal Convention for 1900."

"Our association," continues the Treasurer, "should be the pride and have the support of every photographer in the land. Let's stir ourselves, take more interest in our association and contribute our mite to its sustenance. Attend our meetings occasionally and not depend wholly on our journals to place before us the benefits and advancements our Conventions alone make possible. Join with us this year in the hustle for artistic progress and you will return home enthused, feeling that you have enjoyed a week of profit and pleasure that you could ill afford to have missed." Changing names and dates, there is scarcely a line in the foregoing appeal which may not be addressed to British photographers in regard to the Convention at Gloucester next July. The exhortation which an American professional man delivers to his brethren to attend the Celoron Convention shows that they are greatly in earnest there over their annual gathering, and we trust that such a good example will not be lost on British photographers, who, besides making their own Convention a pleasant outing, can also by co-operative effort render it much more directly useful to them than it is at present.

\* \* \*

ACCORDING to a medical contemporary a laboratory for the application of the Röntgen rays has recently been opened in Madrid, under the name of Instituto Radiografica de España. The Institute, the installation and equipment of which are on a magnificent scale, is said to have cost some two million peretas (80,000*l.*). It is reported that the impression produced by the size of the place, the luxurious manner in which it is fitted up, and the wealth of apparatus which it contains, on the large assembly of medical men and journalists who were present at the opening, was one akin to stupefaction.

\* \* \*

WE are indebted to the well-informed Paris correspondent of *The Daily Telegraph* for some interesting particulars of the manner in which the French Government officially extends its patronage to photography. He tells us that the mayors in some of the out-of-the-way villages of France still have portraits of President Carnot in their offices. The Government of the Republic is determined, however, to remedy this backward state of affairs. Thirty-six thousand portraits of M. Loubet have been ordered by the State, and are to be distributed in April through all the communes in the country. It is further proposed to help the provincial mayors to complete their collections of Republican Presidents, beginning at least with M. Jules Grévy. Portraits of that former head of the State and of M. Faure are to be supplied to those mayors who want them. Nothing is said about Thiers or MacMahon, nor is M. Casimir-Perier's name mentioned in this connexion. It has been pointed out, however, that there are at the Ministry of the Interior 36,000 photographs of M. Faure's predecessor, and that these could easily be sent to the mayors' officials in question. The unused portraits had been ordered from Pierre Petit, and they were sent in before M. Casimir-Perier took the world by surprise in resigning his high post after he had held it only from June 1894 to January 1895.

\* \* \*

INDEPENDENTLY of the portraits of Presidents ordered by the Government, the private and trade distributions of photographs and pictures of two chief magistrates, at least, namely, Carnot and Faure, were enormous. M. Carnot, in particular,

had to compete pictorially with General Boulanger, whose presentments were everywhere. After his death M. Faure came well to the front in the same manner, and kiosks and show-windows are still full of likenesses and drawings of the late President, who is depicted in rigid official evening dress, in sporting attire, in yachting costume, in flannels for boating wear, and, finally, as a motor-man in a horseless vehicle, with a young person representing the Republic beside him. Pictures of M. Loubet are comparatively rare as yet, but they are coming on, and after the Government issue of portraits, in April, they will be nearly as numerous as the sands of the sea. Unfortunately for the lovers of variety, M. Loubet is a strictly official person, and will hardly follow the example of his predecessor, who was fond of ornamental metamorphoses in dress, which gave good scope for pictorial effects.

#### PHOTOGRAPHIC ASSISTANTS AND THEIR FUTURE.

THE letters which have appeared in our columns during the past few weeks from photographic assistants, complaining of the dearth of employment and the lowness of the salaries they are able to obtain, certainly show a very unpromising state of affairs, and it may be well to inquire as to what cause it is to be attributed. It is very evident that at the present time the photographic labour market is much overstocked and the supply exceeds the demand; that is clearly shown by the advertisement columns in our pages week by week, as the number of "situations wanted" are generally more than double those of the "situations vacant," and a not inconsiderable proportion of the latter are for apprentices with a premium, or for improvers at a nominal salary. Under these conditions, is it surprising that so many are out of employment, and that salaries are so low?

We see advertisements of first-rate operators and retouchers, who can take management of a branch, are clever with children, have had many years' experience, &c., according to the claims made, offering their services for thirty to thirty-five shillings a week. If employers can get operators with all these qualifications (!) for that sum, why should they pay more? That is the only business-like way of looking at the matter—and it is a purely business matter—unpleasant though it may be. But do all those who advertise in that way possess the qualifications they set forth? If so, the outlook is bad indeed. The employers frequently say they do not, and there is still a difficulty in obtaining suitable operators for first-class studios. Only a fortnight back we noticed an advertisement for a first-class operator to take charge of a studio, who must be well up in posing, lighting—and artistic, the salary to commence at five pounds a week. Now, it may be asked, if the advertiser could obtain a gentleman with these requirements—and they, and more, are frequently set forth in advertisements by many seeking employment at from thirty to thirty-five shillings a week—why does he offer five pounds a week "to commence with?" The answer is obvious.

We do not doubt that, in the majority of cases, those who advertise their high qualifications do honestly believe they possess them, but it does not follow that others do. Last week our friend "Cosmos" alluded to this subject. We, too, have seen numbers of letters and specimens sent by "first-class" operators in applications for appointments. The former, by the handwriting, orthography, and grammar were quite sufficient to stamp the applicants as being totally unfit to deal with the

*clientèle* of a high class studio, to say nothing of the specimens accompanying the applications. The latter the applicants clearly considered were really good, or, it is obvious, they would not have sent them. It is unfortunate that some persons seem to be quite unable to recognise shortcomings in their own productions, and that alone often leads to disappointment. Although it would seem that the really high-class labour market in photography is not much overstocked, there is no question whatever that the second, third, and fourth-rate is very much so; and the cause is not very far to seek.

In any craft, no matter what, in which a knowledge and a certain degree of proficiency is easily acquired, there is always sure to be a large surplus of labour—such is the case with present-day photography. An engineer, a carpenter or cabinet-maker, plasterer, bookbinder, printer, &c., has to toil for years before he becomes proficient in his work; not so with photography—up to a certain point. With dry plates supplied ready for exposure, with directions for their development, and with the aid of a shilling manual and a camera and lens, any intelligent man can, in a few months, nay, weeks, understand how to expose, and develop, and produce, as photographs, fairly good negatives, and do all that is expected of a dark-room assistant. Let us turn to printing. Much is now done on P.O.P. and on ready-sensitised albumen papers, both of which are now supplied with the formulæ best suited for toning them, and the shilling manual does the rest. Here, again, what great amount of skill or long experience is necessary? If the *employé* can turn out work of good appearance, that generally suits the employer, and it is, in the majority of cases, all he requires. This easily acquired proficiency is evidenced by the fact that in many, even in good second-class, studios the printing and suchlike work is done entirely by apprentices, lads, and girls.

In some cases, where a regular printer is employed, it is surprising the superficial knowledge only that he has of the work. Here is an instance. Some little while ago we received a letter from a printer, who said he had been with his present employer over two years, and had been working with P.O.P. and ready-sensitised albumen papers, but now the employer was talking of having the latter sensitised at home, and, as he had never yet done any, he asked us for a formula for making the sensitising and toning baths, as, unless he could do the work, he should lose his employment. Of course, in all such cases, we are anxious to afford every assistance, and we merely quote this case, amongst others to similar effect, as illustrating the superficial knowledge only that some assistants possess, yet they are able to keep in employment. Still one would have imagined that an *employé* would have made himself, in the time, acquainted with something more than merely using P.O.P. and ready-sensitised papers. It certainly shows lack of enterprise. Several printers who have had to take to sensitising their own paper have written, asking how the bath should be made up to strength if it got weaker, also if it could be decolourised when it got dark and stained the paper, and suchlike queries, yet these men had been filling engagements for years. In many cases, we are sorry to say, employers who have second and third-rate studios, and in some instances doing a fair trade, have no more actual knowledge of photography than the assistants they employ, and therefore are unable to enlighten them.

We have put forward the above facts, unpleasant though they be, to show the reason why so many are at present out of

employment, and the small wages paid. It may be asked, "Where is the remedy?" So long as the present state of things photographic exists, we fear the echo is, "Where!" But there is no gainsaying the fact, that the more proficient a man is in his work the better chance he has of getting employment and the better chance he stands of retaining it.

**Acetylene at Low Temperatures.**—M. Georges Claude has presented a paper to the Paris Academy of Sciences in which he recounts some singular properties of acetylene at low temperatures. He finds that a red-hot platinum wire heated by an electric current can be continuously kept in a solution of the gas in acetone at a temperature of  $-80^{\circ}$  and produces no explosive decomposition. At this low temperature acetone is at its freezing point, and is capable of dissolving as much as 2000 times its own volume of acetylene at ordinary atmospheric pressure.

**Sir W. Crookes on Monsieur and Madame Curie's Discoveries.**—As has been before described by us, these investigators have discovered a body possessing such intense radio-active properties that its results are strongly suggestive of the existence of perpetual motion. Sir William Crookes, in a paper to the above Society, gives his views upon the matter. "It can be conceived," he says, "that uranium, potassium, and iridium . . . have a mixture that enables them to throw off the slow-moving molecules of the atmosphere, while the quick-moving ones smashing on to the surface have their energy reduced while the energy of the body is correspondingly increasing. The energy thus gained seems to be employed partly . . . and partly in originating an undulation through the ether, which . . . must furnish a large contingent of light waves of short wave-length . . . Under ordinary circumstances the difference of temperature would be scarcely perceptible, and the body would then appear to perpetually emit rays of energy, with no apparent means of restoration." [In other words, perpetual motion.—EDS.]

**The New Induction Coil Contact-breaker of Wehnelt.**—We have further information on this remarkable invention in a letter to *Nature* recently, over the signature, John Macintyre, Bath-street, Glasgow. He writes of it in an equally enthusiastic manner to Mr. Swinton as lately quoted by us. The points we raised as to the necessity of control over the character of the spark for its usefulness in Röntgen-ray photography are dealt with, and it is satisfactorily shown that they can be met. "No one can doubt the great advantages of Dr. Wehnelt's instrument in reducing the time of exposure of photographic plates. . . . The question of disadvantages having been raised as to control of the instrument, destruction of tubes, &c., I made a few experiments to see how far such would affect its utility. My experiments were made with induction coils of various sizes, the largest being a twenty-eight inch spark, and in each case the principles involved seemed to be the same. Firstly, we can vary the effects by increasing or diminishing the voltage to the primary cell; secondly, the current is easily controlled by difference in proportion of the sizes of the electrodes; thirdly, the strength of the fluids in which the electrodes are immersed affects the result; fourthly, by the distance between the electrodes in the electrolyte, changes are brought about; fifthly, variations are got by the number of active electrodes. By modifying these we can vary the length of the spark, also its poignancy and thickness, and it naturally follows that we can make use of them in exciting Crookes' tubes. In fact, so easy is it to arrange matters that I have been able to excite small and large tubes of different vacua with perfect safety, even when using a twenty-eight-inch spark coil. . . . Some workers are inclined to think that large coils will no longer be required, but the answer depends entirely upon the work to be done. What we already do know is that coils of any size can do what was beyond their range in the past. . . . Photographs taken by me of deep-seated tissues in the human body have been obtained with very much shorter exposures than by any other means of interruption."

**Wood-seasoning by Electricity.**—Any method of obtaining samples of wood thoroughly seasoned and damp-proof must be valuable to the manufacturer of woodwork for photographic purposes. Every one knows the value attached to, and the price obtainable for, mahogany seasoned by years of keeping, and, if the same effect with others of additional value can be produced in a few days, or even hours, by special means, the price ought to be less and the convenience greater. Not the least valuable of the many processes brought before the public is the Norden-Bretonnean method. A large tank is prepared with an upper and lower lead plate attached respectively to the negative and positive poles of a dynamo, and the wood is placed between, the tank being filled with a solution containing borax, 10 per cent.; resin, 5; and carbonate of soda .75. The current is sent through the plates, and causes the sap to be expelled and the antiseptic solution to take its place. In from five to eight hours the process is complete, and the wood is thereupon removed and dried. Two weeks' natural drying is said to bring about an effect equal to three years' ordinary dry storage.

### VELOX FOR PROFESSIONAL WORK—VARIETY IN COLOUR.

In my previous article, it may be remembered, I referred to the many different colours that are obtainable on Velox, by simply modifying the method of working, and without having recourse to after-toning. Although a great variety of colours may be obtained by toning with different substances, I am of the opinion that it is better to obtain what is required direct in a single operation, rather than where a second, or perhaps a third, is necessary. Moreover, with simple development, we do know of what the image consists, but that is sometimes a little doubtful when the colours are obtained by an after-treatment.

During the last few weeks I have made a very considerable number of experiments with Velox, with different developers and exposures. I find that the paper may be developed with almost any of the developers used for dry plates, for negatives, or for lantern slides, though some answer better than others, so far as pleasing colours are concerned; but for pure rich black I have found nothing equal to the metol-quinone formula issued with the paper. Good red and brown colours may be obtained by using the hydro-quinone developer with a restrainer, such as that given in the ALMANAC for producing warm tones in lantern slides. I have, however, found, when using it, that the image in the shadows is liable to be more or less buried, and of a different tone from that in the lights. When, however, these pictures are viewed as transparencies, the colour is seen to be uniform throughout; but that is not what is wanted in paper pictures.

A most excellent developer for red and sepia brown tones is the M Q developer, the formula for which is sent out with the paper; for black (which I quoted in the former article), diluted, and restrained with a solution of equal parts of carbonate of ammonium and bromide of ammonium, the exposure being increased in proportion as reds or warm browns are desired. It may be mentioned, whether this developer or any other be used, that the colour of the resulting print is dependent upon the exposure given: the longer that is, the redder will be the image, and the shorter it is, the browner will be the picture. A convenient strength for a stock restrainer is:—

Bromide of ammonium . . . . .	$\frac{1}{2}$ ounce.
Carbonate of ammonia . . . . .	$\frac{1}{2}$ "
Water . . . . .	10 ounces.

As a rough guide, with an average studio negative, the combustion of about five inches of magnesium ribbon six inches from the negative, and the M Q developer diluted with an equal bulk of water, and about three drachms of the above restrainer per ounce, will yield a bright Bartolozzi red print. The development will possibly take from eight to twelve minutes. Less exposure and less restrainer will yield the sepia brown tints, and the time of development will be shorter.

The following I have found an excellent developer for reds and sepia:—

#### STOCK SOLUTION A.

Protosulphate of iron (pure).....	2½ ounces.
Water .....	20 "
Sulphuric acid .....	5 minims.

#### SOLUTION B.

Citrate of soda .....	5 ounces.
Citric acid .....	4 "
Water .....	20 "

If, in a few minutes after the addition of the sulphuric acid to the A solution, it remains turbid, with a reddish tint, it shows that the crystals of the sulphate were somewhat oxidised, in which case a few drops more of the acid should be added till the solution is clear and becomes of a very pale apple-green tint; but no more than is really necessary should be used. For use, add one part of A to two parts of B. With this developer less exposure will be required for the red colours than with the M Q. Three or four inches of ribbon will generally suffice, and, for browns, less. The image comes out red at first, and then passes on to the browns if the development is continued. The proportion of acid to the citrate can be varied within some limits, and the citrate of potash may be substituted for the soda salt, though I prefer the formula as given above, notwithstanding that the potash gives a more purple tint to the image. The fixing solution is the same as that given in the formula for the paper for the black tones.

I should have mentioned before this that, for obtaining red and brown colours, the Velox paper should be employed. In the preceding article I recommended, for professional work, the special Velox, but that was for the black tones. For the colours I advise both professionals and amateurs to use the ordinary, as I find that it gives more vigorous results than the special. With the latter the colour in the shadows seems to be too much buried in the film. There are three grades of the ordinary paper—"glossy," "rough," and "carbon." The last-named, by reason of its surface, and the colours it yields, very closely resemble veritable carbon red chalks and sepia. The first-named (the glossy), particularly when the potash citrate is used in place of the soda salt, gives prints very like those on the ordinary P.O.P. I have obtained good browns with the usual pyro-ammonia and the pyro-soda developers, though better with the latter than the former. But I much prefer the M Q, or the iron formulae as given above. I may be asked which of these two I like best? For the browns I prefer the restrained M Q, and, for the reds, the iron, because with the former the browns are quickly obtained, and the reds require a longer development; whereas with the iron the reds come out at once, while the browns require a prolonged development, though with the prolonged development, in either case, several prints may be developing at the same time. The resulting colours, with either of these developers, are much the same in the end.

In professional photography uniformity is essential, as it does not do to issue a dozen, say, of cabinet pictures, all of different tints. Now, uniform results can only be secured by uniform exposure, whatever developer be used. With the ordinary Velox, the exposure to gas to obtain the reds would have to be very long. Daylight, though otherwise good for the purpose, is very inconstant, and would frequently lead to waste of paper. For these reasons I should advise magnesium ribbon, burned at a fixed distance from the negative, as the source of light, and that is what I have used myself—thus we can, practically, measure our light by the inch. My method is this: Nail a lath on the work-bench, say six or eight inches from its edge, against which the printing frame is placed, standing on its side. Now have a piece of stick with a split at the end, into which the magnesium ribbon can be inserted at a right angle. The ribbon is lighted with a spirit lamp, or with a match, and then moved while the combustion lasts. By moving the stick to and fro along the edge of the bench, which serves as a guide, the light is always kept at a constant distance from the negative. During the burning of the magnesium it is well not to breathe on it or let a draught reach it, so that the smoke is not wafted between the frame and the negative, as that might cause inequality in the exposure.

Too much stress cannot be laid on the necessity of uniform exposure, for upon that the colour—whether the various shades of red, sepia, brown, &c.—is dependent, and I hope I shall not be thought dogmatic on this point. I would strongly advise those who work for colours, for the first time, to make the following simple experiment, and the time will not be wasted. Make, say, five small prints from the same negative, giving the first an exposure of one inch of ribbon, the second two inches, and so on, the fifth getting five inches. Then, after moistening the prints in water, put them all at once into a dish of the iron developer, keeping them moving about, and note the result. The longest exposed will come out rapidly of a bright red colour, and the detail in the light will quickly appear. The next print will be a little longer in coming out, and by the time all the detail is out it will be a less bright red than the previous one, and so on. Although all the images are red when they first appear, those with the shorter exposure, and longer development to obtain the detail, become browner and browner before that is secured, yet all may be good prints in the end, though of different colours. In a word, it may be said that the more work the light has done, and the less the developer has to do, the redder will be the image; and, conversely, the less the light does, and the more the developer has to do, the browner will be the finished picture; and this holds good whatever developer be employed. It may be as well to mention that, in practice, it will be found that the brown prints dry up somewhat darker than they appear in the developer, while the red maintain about the same depth, except that they have a less yellow tone when dry.

In the many experiments I have made with Velox, I have met with some curious results (by the addition of different substances to the developer) in modifying colour, amongst which I may mention sulphate of copper. This, by itself, and the citrates, seems to have no developing action, but when added to the iron developer it acts as a powerful accelerator, and modifies the colour greatly, making an image, that would otherwise be bright red, a cold greenish brown, while at the same time it appears to add to the brilliancy of the lights. From ten to twenty minims of a 10 per cent. solution to the ounce of developer has a very marked effect. Most of the results I have obtained in this direction, though interesting to the experimentalist, I have not found to be of any real practical value to professional photographers, therefore I will not trespass on space to describe them.

E. W. FOXLEE.

#### ON DRY PLATES AND THEIR MANUFACTURE.

SINCE the introduction of the gelatine dry plate in 1877-78 an innumerable number of greater and smaller advances have been made, says Herr Vollenbruch in the *Deutsche Photographen Zeitung*. The higher sensitiveness of the dry plates over the wet-collodion plates has made photography a great labour-saver in all kinds of business. As great as has been the advance in the use of dry plates, the preparation of the same stands practically in the same position as it did twenty years ago. The emulsion is made by mixing solutions, which principally contain a bromide, silver nitrate, and gelatine, and then, by subsequent boiling or long digestion of the mixture by heat, generally with the aid of ammonia in order to hasten the ripening. Then subsequently follows the washing of the set emulsion, in order to remove the excess of salt and the products of the double decomposition.

Attempts have frequently been made to replace the troublesome digestion and the boiling by other methods; thus, in 1882, by Burton, and in 1885 by Henderson, whose process is generally used as follows: In a vessel which will hold about 2 litres are placed 4 grammes of hard gelatine, and this is allowed to soak in 150 c. c. of water, and then melted on a water bath, and 5 grammes of ammonium carbonate are added, and then 45 grammes of ammonium bromide, 6 c. c. of a ten per cent. solution of potassium iodide, and 20 c. c. of liquid ammonia (sp. gr. .91), and finally 400 c. c. of alcohol, and the whole allowed to cool. In another bottle are dissolved 60 grammes of silver nitrate in 300 c. c. of water.

In the dark room the two solutions are mixed cold, and the emulsion shaken in a well-closed bottle very frequently for three or four hours. It is then allowed to stand, at an ordinary temperature of about 14° C. for about ten hours. Then 80 grammes of hard gelatine and 20 grammes of soft gelatine are allowed to soak in water, and then freed from excess of water by squeezing, and then the gelatine is melted, and

then poured into the warmed emulsion very slowly and with constant stirring. The emulsion is then allowed to set, and washed for twelve or fourteen hours in running water, and the further treatment is the same as with every other emulsion.

The author states that he has found that the action of electricity in the preparation of such emulsions is extremely simple and gives plates of quite wonderful qualities. The plates prepared with this emulsion possess a delicacy and brilliancy which is to be found in no other plate in the market, and negatives are obtained on them which have all the characteristics of a wet plate; they are absolutely clear and of very high sensitiveness, and surpass even the best transparency plate in fineness of grain.

For the preparation of these emulsions I use a special apparatus, consisting of a large, wide glass or porcelain vessel. On the bottom of the vessel lies a round sheet of lead, 5 centimetres thick, which is connected by a screw and solder with an upright copper wire. This copper wire is provided at its upper end with a binding screw. Beyond this, on a 5 cm. high ebonite foot, is a zinc cylinder, which is platinised inside, and the two are so connected that they make a water-tight vessel. Into the middle of the bottom of this vessel is screwed a silver wire, which is provided on all sides with short arms; this also carries a binding screw. If it is desired now to connect up the electric element, the sheet of lead is laid first at the bottom of the outer vessel. On this lead plate, and in the middle of the vessel, is placed the zinc vessel with the

ebonite bottom, in which is the silver wire, the arms of which should nearly touch the sides of the vessel; there ought to be about 5 mm. distance between the ends of the arms and the sides of the vessel. The binding screws on the silver wire should now be connected by a copper wire with that of the lead plate. This is the necessary apparatus to make the emulsion sensitive, and the diagram explains itself. The arrangement of the apparatus may be such that the battery is separate; in such a case a binding screw should be affixed to the edge of the zinc cylinder, B, and the cylinder may be of any metal, but it must be platinised inside. The negative wire from the battery must then be connected with the cylinder, B, the positive with the silver wire, A.

The process is, briefly, as follows: The gelatine is swollen in water, then melted, and finally mixed with resin dissolved by means of alkali in water, then mixed with a solution of silver nitrate in water, and allowed to set. When set, the silver jelly is broken up and placed in the zinc vessel, B. When filling this vessel, it must be shaken so as to make the particles of jelly settle down to the bottom between the arms of the silver wire, and so that the vessel is evenly filled up to about two-thirds of its height.

The vessel, B, is now placed in position in the vessel, A, so that it stands on the lead plate, C. The outer vessel, A, is now filled up to within 2 cm. of the edge with a solution of magnesium sulphate of a certain strength. Then pieces of sulphate of copper about the size of a hazel nut are thrown in, and the two binding screws, F, F, connected by the copper wire, D, by means of which the very constant electric circuit will be closed.

Now the zinc vessel, B, is filled with a solution of an alkaline bromide which contains two per cent. of its total weight of ammonium chloride. After the lapse of a certain time, the silver in the jelly will be converted

into finely divided silver bromide. The emulsion thus formed is now washed, and the further treatment is as usual.

The duration of the action of the electric current naturally has a very great effect on the sensitiveness; the longer this acts the more sensitive is the emulsion. The strength of the current is also of considerable influence on the formation of the grain and the sensitiveness.

By a small modification of the proportions of the ingredients, I obtained an emulsion which gives absolutely grainless and transparent plates, and of which the sensitiveness is proportionately high. With these plates I have taken photographs in natural colours with short exposures; for instance, a portrait in a studio in a good light taken with a Busch portrait lens with medium stop with four seconds' exposure. The image showed a reproduction of colours corresponding to the original, and the colours were of extraordinary brilliancy and delicacy.

It is very advantageous to be able to do without the mercury dark slide for such work, and to use instead a card, with a thin, polished silver leaf fastened to it as a support for the emulsion. Such cards may be easily prepared by taking a smooth polished card of suitable size, and dusting the same equally all over with resin, in an extremely finely divided powder. On this is laid a real silver leaf of 0.05–0.1 mm. thickness, and passing the two through a well-heated double rolling machine. The passing through must be evenly done, and the dusting on of the resin must be very carefully done and regular and not too thick. The silver leaf should be carefully polished with spirit and the finest levigated chalk, and then carefully cleaned.

To expose these cards the ordinary slide can be used if a sheet of glass be placed in front of the dark slide and another behind the card, and the necessary allowance be made for the thickness of the glass in focussing.

#### COLOUR-SENSITISING PLATES.\*

*Solidblau NG* gives a curve of the Nigrosine type, that is to say, with a weak bath, a band from C—D, and a weaker band D—D½ E; with stronger baths the bands become narrower and a distinct minimum showed itself about D. The action, if only faint, extends to A.

*Chromlederblau B'* gives a curve of the Indulin type; a band from B—D, falling quickly at D and a strong band D—D½ F.

*Chromlederbraun 3 B* gives, with very strong baths, a very faint band from B—C.

*Lederbraun R* sensitises equally from F—D, but not very strongly even with short exposures.

*Benzoflavin II*, an acridine dye, sensitises very strongly. The band from the violet to E is continuous, with a faint maximum from E—F. With weak baths the sensitising is quite equal. This dye ought to be of some practical value, but it has no advantage over acridine orange NO (Leonhardt & Co.), it appears also to slightly lower the sensitiveness, especially with strong baths.

*Phenylenblau R* gives with long exposure a band from A—C, falling quickly, the maximum lying about B. The plates are foggy and give irregular reduction.

*Echtgrau B* and *Echtgrau R* gives very foggy plates and the dye partly separates out in the baths. A faint band at C is visible.

8 KALLE & Co., BIEBRICH.

*Diazingrün*, *diazinbraun*, *diazinschwarz* lower the sensitiveness of the plates in an extraordinary way; even with long exposures no action was visible.

*Diazinblau BR* is a very vigorous sensitiser, which acts in very minute quantities. The sensitiveness is lowered. The band reaches from A almost to D with a vigorous maximum from B—C½ D. A strong addition of alcohol to the bath is required or else part of the dye separates out. There is a tendency to fog.

*Brilliant diazinblau B*. The same remarks as above apply to this dye, only the curve begins at A and reaches to C½ D and the maximum is from A—C.

*Biebericher Patentschwarz RO* and *AN* give no action.

*Tolanroth*, *Rosindulin 2 B*, *Biebericher Indigo B* gave the same results as previously described by Valenta.

*Biebericher Indigo R* gives a weak band B—C with a stronger band D—D½ E, both of which appear with fairly short exposure.

*Naphtamingelb G*, *naphtaminorange R*, *naphtamin orange 2 R* gave no action.

*Naphtaminbraun O B* sensitises very vigorously, F—E.

*Naphtaminblau 3 R*, a weak band C—D.

\* Continued from page 117.

*Naphthaninblau 5 B*, a very vigorous band B—C, visible even with short exposures. With a very weak bath the band extends to C $\frac{1}{2}$ D. Much alcohol entirely stops the sensitising.

*Salicigeb* sensitises weakly to D.

*Chromin G* acts even with short exposures to D, but not very vigorously. At D the band breaks sharp off.

*Directgelb G* is without action.

*Directscharlach G* gives a fairly vigorous band to D, and *Directscharlach B* gives a vigorous band from F $\frac{1}{2}$ D, both with short exposures.

*Indulin R*, weak band, falling from A—D, and a stronger band D—D $\frac{1}{2}$ E.

*Indulin B* acts from A, a vigorous maximum B—D $\frac{1}{2}$ E.

*Nigrosin 3 B*, an extremely vigorous band C—D, with narrow minimum at D, a weaker band D—D $\frac{1}{2}$ E. Great concentration of the baths narrows and weakens the bands.

*Nigrosin R* acts from A, a vigorous maximum C—D, with a somewhat weaker maximum D—D $\frac{1}{2}$ E. The action extends with long exposure right into the infra red.

*Nigrosin F B C grau* acts in almost the same way as the previous dye, but not so strongly.

It is to be regretted that the nigrosines only give useful results with long exposures, as otherwise they belong to a class of dyes which give excellent colour sensitiveness with perfect freedom from fog and a vigorous deposit.

### THE RELATION OF PHOTOGRAPHY TO ART.

(Bronze Medal Paper read before the Edinburgh Photographic Society.)

In choosing for a subject the relation of Photography to Art one feels that he labours under the great disadvantage of coming after a host of others who have written on the same theme. To most who read the current literature of photography it must seem a field reaped and gleaned to the last straw, and they are, doubtless, weary of the apparently interminable, stale, and oft-repeated platitudes that are constantly to be met with. Yet the subject is a very wide one, and it is in the hope that I may be able to adduce something not altogether trite that I venture to make the following observations and suggestions. There is so much "special pleading" in debatable subjects such as this, that one who wishes to write to any purpose must, so to speak, scourge himself into an attitude of impartiality. It is easy to write in the contemptuous manner of many art critics who deny the art claims of photography, and it is so easy to take up the spread-eagle style which characterises certain writers in the photographic journals and claim too much. Perhaps what one feels most strongly in this, as in most other subjects on which opinion and feeling differ, is, that there is an element of right on both sides and that the most important function of any writer is to endeavour to discover the position of the medial line of truth, and to show that in some cases the conflict may be more apparent than real, and in others that there is no necessity for conflict at all.

At the outset, it must be admitted frankly, fully, and without reservation, that the best work of the artist of genius is far superior in almost all essentially valuable qualities to anything yet achieved by the photographer, and, it may be added, to anything that in the future any possible discovery, even the mastery over colour, will enable him to achieve. Yet, after all this has been admitted, photography is valuable—is of very high value, not only in its scientific and merely recording aspects, but as a means of securing those subtle and rare qualities which the artist strives to gain. It was for long the reproach of photography that it could not render what are called "effects." That it is difficult to render in a photograph the rarest, most delicate, and most exquisite of the phenomena of light and atmosphere is true—that it is impossible to secure many of the finest of these effects is not true. But, in order to the highest attainments in this direction, there must first be in the photographer the capacity to see and to feel these things, and also the knowledge of processes and methods by which the tenderest, as well as the most powerful effects may be produced. There can be no doubt that, as time goes on, higher and still higher qualities are demanded in all work that aims at distinction. It is now clearly enough seen that there are two separate, and to some extent conflicting, uses to which photography may be put—the record of what may be called abstract facts for scientific purposes, and the record of beautiful facts for artistic purposes—the one appealing in greatest measure to the intellect; the other, similarly, to the affections. And with the recognition of these two distinct uses all the old mechanical rules are being relaxed, nay, even abandoned, and liberty of practice is claimed and admitted in all directions, a completely satisfactory result justifying in every case the means taken to produce it.

One of the first and most important things the photographer must learn is that nature does not strew her pearls broadcast. The most precious things must be keenly looked for, patiently waited for, and taken advantage of promptly. It almost seems as if we can never get a second chance to secure the finest things. The light changes, and the charm which has endured but for a few moments has gone for ever. Who that has not sketched or photographed realises how quickly the apparently

inert and motionless cloud changes both its position and characteristics? One sees, for instance, a strikingly magnificent cumulus cloud, but, before his apparatus is ready, the grand and unique has become poor and commonplace. Again, the most delightful scenes are the most rare. One reach of the river far surpasses all the rest; in only one nook of the forest, and only one corner of the lake, is the distinctive charm of each attained in highest perfection. The finest and most characteristic specimens of all things are rare and ill to find. We must, therefore, not expect to get the very best things every time we go forth with a camera. It is a mistake to suppose that first-rate pictures can be got by the dozen. Nature is rich, but she has not got such a number of perfect gifts to bestow as many seem to think. Yet, though we cannot get pictures so frequently as we desire, we may find subjects for pictures every day we are abroad, which are to be kept in mind and taken advantage of in suitable conditions of light and atmosphere. To lose a day of grand clouds is a loss indeed. It has been said that in art nothing short of the best can satisfy, therefore no pains should be spared to get perfect work. It is possible even to make certain small artificial improvements on the foreground of a scene which are highly important in the result, but this cannot be done without great care, for the camera is a merciless exposé of incapacity in every direction. Perhaps there is nothing in which skill is more essential than in the introduction of figures into a landscape; and not only is skill necessary, but patience as well. The cost is great, but the gain is correspondingly great. He who would extend his appreciation of all that is striking and beautiful in nature, who would produce work instinct with the finest feelings, would do well to take assistance from the poets. In the pages of Wordsworth and Tennyson, of Longfellow and Whittier, and in many other modern poets, the most exquisite word pictures of natural scenery are to be found, and the characteristics and charms they depict so beautifully and so vividly in words are just of the kind that the photographer requires to look for and to render. Truly there is scope in photography for the highest talent and the greatest industry.

I now wish to offer one or two practical suggestions for increasing the artistic value of photographs, but in doing so I feel a certain diffidence, because I have not been able so completely as I could wish to test the methods I advance. Still the experiments I have made appear to me to be satisfactory. My suggestions may not be altogether new, but I have not noticed them pressed as a means of improving negatives. They are certainly not in common use, and many photographs suffer from the defects they mean to remedy.

The chief suggestion is, that an original negative should be made technically perfect, absolutely sharp, in no part destitute of detail, or, at all events, of gradation, and having as nearly as possible the full range of natural light. From this primary negative a positive transparency should be made, and from that in turn a secondary printing negative is prepared, which may be either the same size, or larger or smaller than the original. The object and advantage of this apparently roundabout process is to enable us to produce a negative of exactly the character required, so that in printing from it no local development or special treatment of the prints would be necessary. It is, no doubt, possible to modify the original negative, and it is desirable to do so as far as practicable, not by reducing or intensifying after-development, but preferably by controlling the action of the developer on different parts of the plate so as to produce the desired result; but any attempt to produce a perfect negative at one operation is, for many subjects, likely to be more or less unsatisfactory. Even if one could tell in the initial stages what changes were really necessary, the extreme variations of treatment on the different parts of the plate, and the extended time of development, would be almost certain to produce markings and other defects that would go far to spoil the negative. The use of a derived negative gives three stages to get at what is wanted, and this must be an undoubted advantage in the process of modifying and harmonising the lights and shadows, &c., and in reducing the wide scale of the original negative to the more limited scale available for a print to be viewed on an opaque surface, as of paper. The result is that the sky is brought up to the requisite pictorial strength, a due amount of lighting is given to the rest of the picture, and the exact degree of force or delicacy aimed at may be ensured. The detail and massing of light and shadow is distributed as desired, sharpness of focus and hardness of line are subdued when necessary, and the whole negative is brought to such a satisfactory state that a succession of similar prints of a particular character could be obtained from it without much, if any, individual or special treatment. It would not be desirable to follow such a course in the case of every negative; but, when the subject is very good, and when there is a fine natural sky, neither time nor trouble should be spared to attain the best result. This method should be far preferable to printing in clouds from stock negatives. It has been truly said that in art nothing short of the best can satisfy.

There ought to be the greatest possible variety in the size, shape, and tone of photographs. The less we speak of whole-plate, half-plate, quarter-plate prints, of sepia, black, and purple tones, the better. It ought, perhaps, to be somewhat of a count against a picture to describe it as a half-plate silver print of a purple tone; not because such characteristics are bad in themselves, but because they are the characteristics of such a vast number, and variety is all-important in pictorial

work. The tones of photographs, especially when of moderately large size, admit of far greater variety than is commonly supposed, and that without going outside the range of colour generally considered admissible.

The scale of the picture is also a point of considerable importance. A really fine and well-balanced picture is generally improved by being enlarged to some extent if originally of one of the smaller sizes. It is not possible to lay down hard-and-fast lines on this point, but it is well worth consideration in each individual case.

The quality and suitability of frame is also deserving of attention. It is hardly possible that a picture can appear to be of value if the frame in which it is set speaks of cheapness, flimsiness, and poor workmanship. The most suitable tone, or tones, for the frame of a particular picture are, of course, best arrived at in an experimental manner.

It is desirable to say something on the subject of the criticism of photographs. It is to be feared that much of the criticism we read and hear is based on very superficial knowledge. In an hour's time almost the points that engage the attention of the average critic can be acquired by any one. A few empirical rules as to composition, the position of the leading object, the disposition of the principal lines, opposition of horizontal to vertical, straight line to curve, and a few superficial notions as to the production of sentiment, are too frequently the whole stock in trade of many who pretend to critical skill. Such a person may quite easily point out small blemishes or defects, but, if he has not studied both art and nature long and patiently, he cannot discover good qualities which far outweigh the petty deficiencies he can so quickly discover. As a matter of fact, no photograph of any consequence has ever been, or ever will be, taken, in which the numerous little discords of nature (if such they may be called) do not appear, and it is absurd to lay much stress on them. Besides, it must be remembered that there is a harmony that cannot be seen, but only *felt* to exist. It is not alone the "elevation," so to speak, that must be harmonious; the "ground plan" and every conceivable "section" of a picture must be *felt* to be harmonious, even when the harmony cannot be directly seen. Again, *surfaces*, as well as lines, must be *felt* to have beautiful curvature, and where are the recipes and formulæ that can confer keen perception and fine feeling for all the phenomena that exist in the infinite domain of nature?

If the highly skilled painter, by taking advantage of the selection of materials for his picture, by the use of colour, and by the various kinds of suggestions that he can obtain from the endless methods of applying pigment, can reach heights of excellence impossible to the photographer, yet his scope is, either from necessity or choice, far more limited. It is unquestionably the case that artists, as a class, are prone to notice only those effects that have been painted over and over again. Without presuming to make a comparison on general grounds, one cannot help feeling that, at every exhibition of photographs and lantern slides, he sees a greater number of fresh and striking aspects of nature depicted than in the average exhibition of paintings. This freshness is particularly noticed in photographs of sea and sky, which often also give such force of presentation as no painting can rival. The surface of water, nature's own mirror and kaleidoscope, is ever changing and ever beautiful. How vast the change from the still evening lake, whose inverted world is tremulous with myriad needles of reflected light, to the storm-tossed sea when the waves, crowned with spray and wreathed with foam, surge around the giant boulders of a rock-bound coast. Again, how vast and varied are the glories of cloudland, from peaceful flocks of sunset cloud to those majestic piles of lurid vapour where the powers of the air are imprisoned. In all these phases of natural loveliness or majesty, and in all that lie between, the camera has revealed undreamt-of visions of beauty, so rare and so elusive that through the centuries they had remained invisible to the painter's eye.

Let it not be supposed that pictures of those works of the Creator that we esteem beautiful are valueless because they are self-portrayed by means of the light by which our eyes see them, and that only those pictures are to be prized that present nature as modified by some one who chooses to call himself an artist. Such an idea, common as it is, can surely not bear to be plainly stated. It should be remembered that the action of the artist is not pure gain. Indeed, in the case of inferior artists, it is not seldom pure loss, for they give us either nature as if out of a mud bath, or arrayed in a gaudy, meretricious garb, rarely in the modest and pleasing colour which is her delight; and, at the best, how often do they give us merely the *complexion* of nature, despising form and almost all that speaks of vital forces. It is with strange feelings one hears such artists, as if from some sublime elevation, speaking patronisingly of photography, and in utter magnanimity deigning to be kind, when they might justly be severe. But, after all, why should photographers care much whether the quality of art be or be not attributed by artists to their work? Its power to confer instruction and delight is just the same, although this little word of three letters is unheard of in connexion with it.

I cannot see that an earnest and successful worker in photography has any cause to feel ashamed of his choice of a pursuit. For one whose time and energies are mainly occupied in the daily work by which his livelihood is obtained, to photograph is, in the great majority of cases, a more honourable, because more wise, choice than to paint from nature. The time at the command of most amateurs is quite sufficient

to gain the requisite manipulative skill and to provide the opportunity for doing successful photographic work; but the amateur painter cannot hope to produce tolerable, far less admirable, work, unless he is decidedly gifted, possessed of exclusive devotion to his work, has more than the average share of leisure, and the advantage of some professional tuition as well—a combination of circumstances rarely to be met with.

Photography carries with it most of the advantages that other recreations possess—open air, exercise, emulation if desired; but, distinctively, and in largest measure, it has an educative influence of the most delightful and varied kind, and it keeps ever fresh those reminiscences of happy days and distant scenes which might otherwise have completely faded with lapse of years from the pictured page of memory. Let the photographer be proud and glad of the extent, variety, and richness of the field of his labour, and, if he cannot, like the painter, transfigure nature according to his individual fancy, or distort her after his caprice, let him rejoice that he is more likely to display the beauty that the Creator intended to be seen, admired, and enjoyed by all.

JAMES CRAIG.

## ADUROL AS A DEVELOPER FOR NEGATIVES.

[Report by Mr. C. H. Bothamley, F.I.C., F.C.S.]

I HAVE investigated the developing powers of a specimen of adurol received from Messrs. A. & M. Zimmermann. It was enclosed in the original cardboard packet bearing the name of E. Schering & Co.

Adurol is a white semi-crystalline powder which dissolves fairly easily in water and more readily in solutions of sodium sulphite and potassium metabisulphite. A thin layer of the solid substance was left on a glass plate in free contact with the air for more than a fortnight, but at the end of that time it showed no discolouration, and had not in any way altered in appearance. An aqueous solution exposed in a dish to the action of air for a fortnight acquired only a slight brown colour without formation of any precipitate; a solution in a ten per cent. solution of ordinary sodium sulphite under the same conditions became pale yellow only, whilst a solution in a ten per cent. potassium metabisulphite solution remained quite colourless.

It follows from these observations that adurol undergoes little or no recognisable alteration when exposed to the air under conditions more severe than would be met with in actual practice. It is even less liable than hydroquinone to discolour through the action of air, whether in the solid state or in solution.

Two formulæ are recommended by the makers; one for a concentrated solution containing both adurol and the alkali, whilst the other is far more dilute and separate solutions of the adurol and the alkali. They are as follows:—

### I.—CONCENTRATED MIXED SOLUTION.

Water .....	400 parts or 7 ounces.
Sodium sulphite .....	75 " " 1½ "
Potassium carbonate .....	150 " " 2½ "
Adurol .....	15 " " ¼ ounce.

For use, dilute with from five to seven times its volume of water.

### II.—SEPARATE SOLUTION.

#### A.—Adurol.

Water .....	500 parts or 16 ounces.
Sodium sulphite .....	50 " " 750 grains.
Adurol .....	10 " " 150 "

#### B.—Alkali.

Water .....	500 parts or 16 ounces.
Potassium carbonate .....	60 " " 900 grains.

For use mix in equal volumes.

I have made experiments with several different brands of plates typical of those in use in this country and find that adurol acts in a very satisfactory manner with all of them, working fairly rapidly and yielding negatives of excellent vigour and gradation and of a good black colour.

It is immaterial whether the first or second formula is used; the only difference observed is a slight difference in the rate of action, due to the difference in the strengths of the solutions. Diluting the developer, in fact, affords a useful means of controlling its action.

The image, with a normal exposure, begins to appear in from thirty to forty seconds and builds up gradually, in much the same manner as with pyrogallol. Development is complete in from three to four minutes. It is noteworthy that the developer works with very fair rapidity and gives sufficient opacity, even when comparatively cold.

There is no tendency to produce stains and almost no tendency to produce fog, except perhaps in the case of very rapid plates, and the tendency is readily checked by addition of a small quantity of potassium bromide.

Potassium bromide in the developer has a very marked restraining effect, and gives distinctly increased printing contact in the negative if development is not pushed to the limit. By the use of bromide, development can be kept under control, even when there has been considerable

over-exposure. Half a grain of potassium bromide per ounce of mixed developer exerts a marked effect, and with one grain per ounce development becomes rather slow, though not so slow as with hydroquinone under similar conditions.

The same quantity of developer can be used for several plates in succession, its action, of course, becoming gradually slower.

Even when the developer is left in the dish for half an hour after being used for the first time, the diminution in its developing power, though distinct, is not very strongly marked.

I find that adurol can be used with sodium carbonate with very good results. The adurol solution given under formula II., when mixed with an equal volume of a ten per cent. solution of soda crystals, forms a developer that acts somewhat more slowly than when potassium carbonate is used, but nevertheless acts quickly enough for all practical purposes. Potassium bromide in this developer has a distinct restraining effect without making the development so tediously slow as with hydroquinone under similar conditions. Adurol soda with potassium bromide, not exceeding one grain per ounce, is, in fact, a very useful developer for dealing with over-exposed plates or with normally exposed line subjects.

If the proportion of adurol is reduced whilst that of alkali is increased, e.g., one volume of adurol solution and three volumes of alkali solution, the effects are similar to those observed with pyrogallol; the appearance of the detail is relatively accelerated, whilst the growth of opacity in the high lights is retarded, the result being that, unless development is pushed to its utmost limit, the printing contrasts of the negative are distinctly reduced. There is, therefore, some power of correcting for moderate under-exposure.

Speaking generally, I find that the claims made for adurol are well founded. It is a developer that combines the cleanliness, freedom from stain and fog, with the power of giving vigorous negatives, that characterise hydroquinone, whilst at the same time its rapidity of action is practically equal to that of pyrogallol. It also has the great advantage over hydroquinone that the use of caustic alkalies is unnecessary, since, with potassium carbonate, and even with sodium carbonate, development is quite sufficiently rapid to meet all requirements.

It follows that adurol is a developer of very considerable value for general work, and it also promises remarkably well as a developer for line subjects.

#### ON HYDROGEN PEROXIDE AS THE ACTIVE AGENT IN PRODUCING PICTURES ON A PHOTOGRAPHIC PLATE IN THE DARK.

[A Paper read before the Royal Society, March 2, 1899, and reprinted from *The Chemical News*.]

In previous papers it has been shown that certain bodies are able, in the dark, to act on a photographic plate and produce a picture. The purpose of the present communication is to show that, in all the cases which have been examined, and probably in all others of a similar kind, the action which occurs is due to the presence of hydrogen peroxide. As a sensitive plate always contains moisture, and probably would be inactive if quite dry, it does not seem possible to test the truth of this statement by the total exclusion of moisture; therefore more indirect means have to be adopted. In the following paper no attempt is made to explain the reactions which occur in the plate itself; that is a distinct question, and at present the object is to consider the means by which these changes, whatever they may be, are brought about. These changes are rendered visible by exactly the same processes as those adopted for the development of an ordinary light picture. Any of the ordinary photographic plates may be used in these experiments; but, as many of the pictures are only formed after a long exposure, it is well to use rapid plates. In the following experiments the plate used has been in almost all cases the Ilford special rapid, and the process of development has in every case been that recommended for their ordinary use.

The first step towards demonstrating that hydrogen peroxide is the active agent in producing these pictures is to show that all the results produced both by metals and by organic bodies on a photographic plate can be produced by hydrogen peroxide. This body is now made in considerable quantities and sold in aqueous solution of a given strength. This commercial article appears to act equally well to a carefully prepared and pure specimen of the same strength.

A convenient way of testing the action of any liquid on a photographic plate is to use a small circular glass dish, such as is made for bacteriological experiments, the photographic plate resting on the top of the dish, and the amount of the liquid used determines the distance the plate is from the active surface, the experiment being carried on in complete darkness. If pure water be tested in this way, it is found that no picture, that is, no darkening of the plate, occurs on its being treated with the developing solution. The plate can be left over the water for eighteen to twenty hours, but, if left longer than this, the film is destroyed by the aqueous vapour. If to the pure water in the dish a mere trace of hydrogen peroxide be added, a darkening of the plate will quickly occur.

For instance, if the liquid contains only one part of the peroxide in a million of water, and the plate be exposed to its action for eighteen hours, a faint picture is produced. Bearing in mind the small amount of

evaporation which takes place under these conditions, and consequently the minute amount of the peroxide which comes in contact with the plate, it clearly shows the exceeding delicacy of the action.

Again, if a piece of Ford blotting-paper, which by itself is inactive, be wetted with a solution of one part of peroxide in 500,000 of water, and be hung up in a warm room for three-quarters of an hour to dry, and placed in contact with a photographic plate for two hours at a temperature of 55° C., on subjecting the plate to development a distinct picture is produced. In fact, moistening good blotting-paper with a solution which may be strong or weak, and allowing it to dry for a long or short time, is a very good way of applying the peroxide. In place of blotting-paper any inactive porous substance may be used.

Plaster of Paris wetted with a peroxide solution and allowed to set continues for a long time to be an active body. If by any of these means a large, in place of a small, amount of the peroxide be allowed to act on a plate, then, in place of a dark, a light picture is obtained, a phenomenon similar to what is known to photographers as reversal.

The conditions under which certain metals and certain organic bodies act on photographic plates, and how pictures of the structure of paper, skeleton leaves, lace, and other bodies can be obtained, has already been described, so that now it is only necessary to say that substitute for these active bodies peroxide of hydrogen and exactly corresponding results are produced. Writing with ordinary ink, or with a solution of ferric sulphate, or potassium ferrocyanide, has been shown to be opaque to the action of zinc and of turpentine, so is it to the action of the peroxide of hydrogen. Further, the action exerted by the metals and the terpenes is unable to pass through glass, mica, selenite, &c., but is able to pass through thin sheets of gelatine, celluloid, gutta percha, indiarubber, tracing paper, gold-beaters' skin, parchment, &c.; peroxide of hydrogen acts exactly in the same way, every body which is known to be either opaque or transparent to the action of the metals or terpenes is opaque or transparent to the action of the peroxide, so that, as far as the production of similar phenomena goes, the agreement is complete. Of the acknowledged tests for the presence of hydrogen peroxide, the one with the titanous acid dissolved in sulphuric acid is exceedingly delicate; so also appears to be the tetra-methyl-paraphenyl-enediamine paper of Dr. Wurster, and both of them have been made use of.

The next point which naturally suggests itself is, whether peroxide of hydrogen is, or is likely to be, present in all the different cases, when action on the sensitive plate occurs. First, with regard to the metals. The list of the active metals, which has already been given, is as follows, arranged approximately in order of their activity: Magnesium, cadmium, zinc, nickel, aluminium, lead, cobalt, bismuth, tin. Now, these are certainly the metals which might be expected to decompose water, and in the presence of oxygen cause the formation of hydrogen peroxide, and still more the order in which they stand in the above list, judging from their general properties, is that in which they would probably induce the formation of the peroxide. It is also satisfactory to note that this list of metals and their order of activity was drawn up simply from experiment, when there was no idea that hydrogen peroxide had anything to do with the reaction. Again, as a confirmation that hydrogen peroxide is formed when these metals oxidise in moist air, pieces of Dr. Wurster's tetra paper were moistened and laid on bright surfaces of the metal. With the metals that head the foregoing list a considerable amount of blue colour was rapidly developed; with the metals at the end of the list the amount of colour was less, and the reaction slower; and with other metals, such as silver and platinum, there was no action. With copper and with iron a very slight amount of action did occur, but these metals do not appear able to produce definite pictures. Iodide of potassium and starch paper, where used in the same way, gave a blue colour with all the active metals, but none with copper nor with iron.

On the supposition that hydrogen peroxide is the active agent in the action exerted by the metals, it seemed probable that, on supplying to the metal more moisture than it obtained from the air and photographic plate, more action would take place, and this was found to be the case. Two pieces of polished zinc were placed in contact with photographic plates in small iron boxes; one box was quite dry, and put in a bell jar over calcium chloride, and into the other box some damp paper was introduced, and the box was placed with a little water under a bell jar. On examining the plates after three days, it was found that the damp plate had much the darker picture on it.

With the object of obtaining an increased amount of action, experiments were made by passing a current of warm moist air over zinc turnings. A glass tube, six feet long and one inch in diameter, was packed with zinc turnings and placed within a large brass tube to which steam could be admitted. The amount of action, if any, was indicated on a plate, placed in a dark box at the end of the tube. Even under the most favourable conditions no very large amount of action took place. When a current of moist warm air was passed through the tube for an hour, a fairly dark picture was obtained. If the air was dry, no picture appeared. If amalgamated zinc was used in place of pure zinc, a darker picture was formed, and, as a check on these results, dry and moist air, both warm and at ordinary temperatures, was passed through the tube, no zinc being present, and then no action took place; also, when ozonised air was passed through the tube, there was no action. Passing now from the metals to the organic bodies capable of acting on a photographic

plate, it has been found that they belong essentially, if not solely, to that class of bodies known as terpenes, and it is a general property of all this class of bodies when oxidising to give rise to hydrogen peroxide. Thanks to Dr. Tilden, experiments have been made with most of the terpenes, and all were found to be very active bodies; both pinene and limonene were tried, in their dextro and lævo-rotatory state, but their activity appeared to be the same. Oxidised and other compounds connected with the terpenes, such as terpineol camphor, thymol cymene, have no power of acting on a photographic plate, but ordinary turpentine and terebene are very active bodies.

Most of the ordinary essential oils, such as bergamot, peppermint, pine, lemons, cajuput, &c., have been experimented with, and, without exception, have been found to be active bodies. It is well known that they all contain terpenes; they are also characterised by a strong odour, and, as ordinary scents contain some of these bodies, it follows that almost all vegetable bodies having a strong smell are capable of acting on a photographic plate. Eau-de Cologne gives a good picture, so do many wines and brandy, and coffee, guaiacum, cinnamon are also active substances; thus the photographic plate becomes a very delicate test for the presence of all these bodies, and, as the action is cumulative, it may even compete with the sense of smell.

In addition to the essential oils, the ordinary vegetable oils, such as linseed oil, which is the most active, and colza and olive, which are much less active and have much less power of absorbing oxygen from the air, can act on a photographic plate. The tetra paper readily goes blue if suspended in a bell jar which has a few drops of linseed oil in a dish within it.

The mineral oils are, on the contrary, devoid of this power of acting on the sensitive plate, and the same applies to bodies such as benzine, phenol, naphthalene, aldehyde, methyl alcohol, coal naphtha, &c.

It would seem, then, that all the organic bodies capable of acting on the photographic plate are capable of giving rise to the formation of hydrogen peroxide when they oxidise in moist air.

W. J. RUSSELL, Ph.D., V.P.R.S.

(To be continued.)

#### DEKKO PAPER.

MR. EDMUND A. ROBINS, Lecturer to the Aldenham Institute, gave a series of demonstrations of Dekko paper at the Croydon Camera Club-rooms on Wednesday, March 15, which attracted an audience of about forty members, amongst whom were several of the leading photographers of the town.

In the course of his opening remarks, Mr. Robins stated that the paper, which was only introduced to the notice of photographers about a month ago, is made in four grades, ranging from enamel-like surface to rough texture. The lecturer claimed that the paper would print, at the will of the operator, in colours extending from blue-black to black, brown, warm brown, red, and purple. To illustrate the variety of colour possible, a number of delightful prints of somewhat large dimensions were displayed on the walls, and others handed round. These fully bore out the lecturer's contention as to the large range of colour attainable. Our readers may like to be reminded that Dekko is a paper which is handled much as is bromide paper, with the important exception that, although it may be printed by gaslight, it may be developed without needing a dark-room light, but in any room as ordinarily lit. Of this the lecturer began by giving his audience ocular proof. Taking a sheet of paper from its packet, and standing within seven feet of a brightly burning incandescent electric light, the paper was placed under a negative, and an exposure of twenty seconds given to two gas burners at a distance of about six inches. The print was taken out, with the same bright light shining, and developed in an uncovered dish. The image began to appear in about twenty seconds, development being complete in about one minute. The resulting tone was a warm black. Subsequently Mr. Robins showed how, by prolonging the exposure and modifying the developer, various other tones could be obtained. In this regard he described a developer which had been found particularly successful, the ingredients of which had not as yet been published:—

Metol .....	8 grains.
Hydroquinone .....	80 "
Sodium sulphite .....	2 ounce.
Sodium carbonate (crystals) .....	3 "
Water .....	100 ounces.

In using the above, add to each ten ounces half a fluid ounce of a ten per cent. solution of hypo. With this the lecturer produced several charmingly toned pictures. The development is much slower than where a black tone is aimed at, and, if it is stopped when a yellow brown is reached, on placing the print in the fixing bath (alum hypo) a beautiful Bartolozzi red results. By leaving the print longer than needed for fixing, the red gradually changes to brown, and then to purple brown; in this way the operator can greatly and easily modify the tones. This action is also, at times, useful in correcting errors of exposure; an over-exposed and under-developed print may be hardened and strengthened by the action of the fixing bath, which slightly reduces the high lights and fortifies the shadows.

## Our Editorial Table.

GRIFFIN'S PORTABLE PREPARATIONS FOR PHOTOGRAPHY.

John J. Griffin & Sons, 20-26, Sardinia-street, W.C.

MESSRS. GRIFFIN have now added to their list of above Velox mountant in bottles and tubes. Their excuse for increasing the already large number of mountants on the market is that users of Velox, bromide, gas-light development, and other stout papers frequently find trouble in getting their pictures to grip the mounts, the tendency to peel at the corners being more noticeable in the rough papers which incline to absorb

the solution. The Velox mountant is made with specially strong adhesive powers. It is always ready for use, is free from acid or other contaminating substances, and keeps well. The composition, having no excess of water, should be spread rapidly and sparingly, and, if this is done with care, squeezed glazed prints may be mounted without loss to surface.

The collapsible tube, containing two ounces of mountants, Messrs. Griffin believe will be welcomed by many photographers who require small quantities of mounting material in a convenient form.

#### THE FRENA PNEUMATIC FLAP SHUTTER.

R. & J. Beck, Limited, 63, Cornhill, E.C.

MESSRS. BECK have for some time felt the desirability of introducing a flap shutter for use with their Frena camera when slow exposures are required—exposures, which are yet too quick to be made satisfactorily with the ordinary time-exposure arrangement. The Frena pneumatic flap shutter is made to fit on to the front of the camera in such a manner as not to interfere with the use of the magnifiers. Great care has been taken in designing it to prevent there being any jar to the camera when the flap is raised, and to ensure its shutting firmly at the end of the ex-

posure. The flap is lined with velvet to render it light-tight. The shutter of the Frena camera gives exposures from one-eightieth of a second to one-fifth of a second, and, for time exposures, it is necessary first to set the speed plate to one-fifth of a second, after which the set-off bolt must be pulled out to open the lens; it can then be left for as long an exposure as required, and the lens again closed by pushing in the bolt. This is all that can be desired for long exposures, but it is not satisfactory for intermediate ones, say, from one-fifth of a second to ten seconds, as it is difficult to perform the double movement without shaking the camera.

It is, therefore, for this class of work that the Frena pneumatic flap shutter has been designed. The method employed for fitting the shutter is such that it is not necessary for it to be permanently attached to the camera. A base plate is supplied with each one, which can be fixed to the different-sized cameras, as directed below. On this are three small projecting catches, by means of which the shutter can, with ease, be put on or taken off as required. The instructions for use are: Set the shutter speed plate to one-fifth of a second, and fix on the flap shutter. Pull out the set-off bolt. The camera is now ready for use. To make an exposure squeeze the pneumatic ball, when the flap will open and remain open as long as the ball is pressed. On finishing the exposure the set-off bolt should be pressed in.

#### THE CLIMAX ALBUMENISED PAPERS.

J. J. Griffin & Sons, 20-26 Sardinia-street, Lincoln's Inn-fields, W.C.

MESSRS. GRIFFIN write us: "There have been several remarks relating to albumen paper in your recent issues, and this has prompted us to send you particulars of our 'Climax' papers, the existence of which you may not be aware of. These papers present distinct advantages to high-class professional photographers, for whom they are specially made. We do not consider that they come under the class of ordinary ready-sensitised papers, for the reason that the acid is applied in a separate floating, and consequently, if the paper is thoroughly washed before toning, no contamination of the toning bath takes place. You therefore get the advantage of acid in the paper without its drawbacks. The superiority of a paper floated in this way over home-made sensitised paper is that it gives you a wider range of contrast in the shadows and prints about twice as quickly. The paper we are at present preparing is quite as quick as any gelatino-chloride paper on the market. We make the paper in two or three grades."

The pamphlet Messrs. Griffin send us gives particulars and formulae for the manipulation of their Climax papers, and is to be had on request. Albumen papers with characteristics such as those claimed for the Climax papers should be popular.

#### CATALOGUES RECEIVED.

Parkin & Fry, 31 and 33a, Sandstone-road, Liverpool.

MESSRS. PARKIN & FRY's catalogue apprises us that they undertake bromide enlargements on paper and opal, carbon enlargements on paper and opal, carbon prints on ivory, the production of negatives, lantern slides, platinotype enlarging, and many other departments of photographic work. Carbon tissue, bromide opals, dry plates, bromide paper, and printing-out paper are also made by the firm, whose works are at Etna Mills, Old Swan, Liverpool.

Jonathan Fallowfield, 146, Charing Cross-road, W.C.

MR. FALLOWFIELD is holding a special clearance sale of surplus stock to make room for new goods for the present season, which, in Mr. Fallowfield's opinion, promises to be an exceptionally good one in the photographic trade. The articles for clearance are detailed in four lists. They comprise general photographic goods, apparatus, dry plates and films, and mounts. Innumerable bargains are offered, and we advise our readers to give the sale particular and immediate attention.

FROM MESSRS. A. & M. ZIMMERMANN, of 9 and 10, St. Mary-at-Hill, E.C., we have received a little book which treats of the photographic preparations of the Actien-Gesellschaft für Anilin-Fabrikation of Berlin. Full directions for the use of rodinal, alkonogen, diogen, amidol, glycin, metol, para-amidophenol, diphenal, and ortol are given. The booklet, which is a distinctly useful one, is supplied free to dealers for distribution.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, March 22, at eight o'clock. Travellers' Night. "Lowestoft and Neighbourhood," by Mr. H. Vivian Hyde.

THE ITALIAN EXHIBITION.—The name of Mr. Ralph W. Robinson was inadvertently omitted from the list of contributors to the Invitation Section of this Exhibition.

MESSRS. ARCHER & SONS, of Lord-street, Liverpool, having bought the business of Messrs. Wood Brothers, are holding an annual sale to clear out the latter's stock.

THE Thornton-Pickard Manufacturing Company, of Altrincham, inform us that, notwithstanding increased competition, the sales of their shutters and cameras are larger than hitherto.

ON Wednesday, March 15, the members of the South London Photographic Society held a Cinderella dance at the Surrey Masonic Hall, Camberwell, S.E. Some two hundred ladies and gentlemen attended, and a programme of fifteen dances was gone through. There was a quadrille—"La Société Photographique du Sud de Londres."

ROYAL PHOTOGRAPHIC SOCIETY.—Technical Meeting, Tuesday, March 28, at 12, Hanover square, at eight p.m. "Ozotype with Carbon Tissue, a new method of Pigment Printing," by T. Manly.

THE AUSTIN-EDWARDS MONTHLY FILM NEGATIVE COMPETITION.—The prize camera for the current month has been awarded to Mr. J. C. Oliver, 2, Royal-terrace, Glasgow, for his negative, *Buchanan-street, Glasgow, at Night*.

MESSRS. TAYLOR, TAYLOR, & HOBSON inform us that, on and after March 9, all their London business will be transacted at No. 18, Berners-street, W., these premises being more convenient than the present offices in the Charing Cross-road. Their telegraphic address will remain as before, "Illiquo, London."

THE names of the prize-winners in the Warwick Monthly Competition for March are:—1st prize, 10s., *Portrait Studies of Child*, Mr. H. J. Dalby, 82, Wellington-street, Woolwich; 2nd prize, 5s., *Hard Times*, Mr. A. E. Casson, Burlington-road, Withington, near Manchester; 20 prizes 1s. each: Dr. J. W. Ellis, Messrs. J. C. Oliver, Arthur Waterall, J. D. Murray, L. Bagshaw, Nichol Elliot, Ralph W. Robinson, Frank M. Sutcliffe, William McLean, Jas. C. Kingdon, H. R. Campion, A. W. Cooper, T. H. Baker, John H. Coath, F. B. Kempe, Ernest Wood, H. C. Leat, Edward Brightman, Misses Amy Nott, H. Phillips.

MESSRS. A. & M. ZIMMERMANN, of 9 & 10, St. Mary-at-hill, write: "In your issue of the 10th inst. we notice an article on 'Magnesium Cartridges,' which you say is due to the inventor, Mr. York Schwartz, Hanover. As we are agents for Mr. York Schwartz in this country, we immediately asked him why he had given publicity to the process of making magnesium flashlight powder and cartridges. He informs us to-day that he never communicated the article to you, and that no doubt it was taken from the English patent No. 27,115. Under these circumstances, we shall thank you to make it known that Mr. York Schwartz's specialities are patented, and that the article was not communicated by him, and that it is merely a copy of the patent."

THE BIRTAC AT THE ROYAL INSTITUTION.—By request, Mr. Birt Acres gave a demonstration of the "Birtac at Home Animated Photography" at the Royal Institution, Albemarle-street, W., on Friday evening last. Mr. Acres used his new gas-pressure apparatus, by means of which, using the gas from the ordinary house supply, a greatly increased pressure of gas was obtained with a correspondingly great increase of the light obtained from an incandescent mantle. This new gas apparatus works in conjunction with the projecting apparatus for showing the animated photographs, and is, to all intents and purposes, automatic, as the turning of the handle to show the photographs actuates the compressing apparatus; and, further, it is automatically governed, so that a child could work it with absolute safety.

THE Annual Dinner of the North Middlesex Photographic Society was held on Saturday evening, March 18, at the Holborn Restaurant. The President (Mr. J. C. S. Mummery) occupied the chair, and he was supported by about sixty members and friends. The toasts included "The Society," "The Photographic Press," and "The Visitors." During the course of the evening the certificates awarded at the recent Members' Exhibition were presented to the successful competitors by Mr. F. Colin Tilney, who was one of the Judges. From the remarks of the President in reply to the toast of the Society, it appeared that the North Middlesex Photographic Society is in a thoroughly sound and healthy state. Songs, music, and recitation greatly added to the enjoyment of the evening, which passed off with the greatest success.

G.E.R. MECHANICS' INSTITUTION (PHOTOGRAPHIC SECTION).—This Society held their Sixth Annual Exhibition on the 14th and 15th inst., and it does great credit to Mr. H. W. Bennett (who has been delivering a course of lectures to the society during the past six months) to be able to record a very marked advance in the quality of the members' work over that of the previous exhibitions. The loan pictures included those of the Affiliation, and others by Messrs. The Sandell Plates and Films, Limited, H. T. Malby, H. Wilmer, S. D. Holden, and F. Moore & Company. There was a cinematograph display each evening. Mr. S. D. Holden lent and worked a photo-chroscope, as did the Rev. H. W. Gresswell a Röntgen-ray apparatus. The South London Society lent their lantern lecture and slides illustrating a holiday in Rotterdam, and some members' slides were also put through the lantern. Messrs. Reginald W. Craigie and F. Seyton Scott kindly acted as Judges, and awarded the medals as follows:—Open Class, for General Work: Silver medal, *A Summer Evening*, by Mr. H. W. Bennett; bronze medal, *An Essex Backwater*, by Mr. S. C. Stean. Members' Classes (1) Landscape: Silver medal, *Where the Birch and the Brake do Grow*, by Mr. H. D. Banks; bronze medal, *Silver Birches*, by F. Hammond. (2) Architecture: Silver medal, *Bishop Fox's Chantry, Winchester Cathedral*, by J. H. Ayling. (3) Marine: Silver medal, *Bound for the Fishing Ground*, by J. K. Ayling; bronze medal, *The Incoming Tide*, by H. D. Banks. (4) Portraiture: Bronze medal, *A Faithful Servant*, by H. W. C. Drury. (5) Instantaneous: Silver medal, *On the Fasel*, by C. W. Harris; bronze medal, *A Scrum Breaking-up*, by H. D. Banks. (6) Lantern slides, in sets of six: Silver medal, *Landscape*, by J. K. Ayling; bronze medal, *Forestry*, by C. Harding. Consolation prize to W. S. Rogers for a frame of quarter-plate pictures. This prize is given to the best picture exhibited by a member who has never taken a prize.

BRENTFORD PHOTOGRAPHIC SOCIETY'S EXHIBITION.—The first Exhibition held under the auspices of the Brentford Photographic Society was opened on Wednesday, March 15, at St. Paul's School Annexe, by the President (the Rev. T. Eland, M.A.). The Society has hardly been in existence six months, and some amount of misgiving was felt at the idea of holding an Exhibition at so early a period in their history. Happily, all gloomy prognostications of failure were doomed to non-fulfilment, and the success of the Exhibition, which was continued on Thursday evening, was beyond the expectations of the most optimistic. The room was kindly lent by the Managers of St. Paul's Schools, and at the opening there was a large attendance of visitors to inspect the exhibits, exactly 100 in number, which were well ranged on the walls. For a beginning the number is very encouraging, while the quality of the exhibits was of a high order, there being among them some very beautiful pictures. The result, on a whole, is certainly very creditable to the organizing

ability of the Hon. Secretary (Mr. Hilton Grundy) and the members of the Committee, while the President himself has taken a great personal interest in the affair, sending some pictures not for competition. The Exhibition was divided into three sections—Members' Class, Members (not for competition), and Open Class. In the Members' Class three prizes were offered by the Society, the first being a silver medal, and the second and third the choice between an ekronometer and a Watkins' exposure meter. The first prize was secured by Mr. A. R. Read, junr., who had on show a splendid collection of platinum and silver prints, for his picture *After Love*, one of a series displaying beautiful sky and cloud effects. Mr. A. R. Read, senr., came second with a variety of prints. Of these two flower studies were selected for special commendation, one representing *Autumn Queens* (silver), and the other *Cherry Blossom* (platinum). All gave evidence of careful treatment in every department. The third prize was awarded to Mr. E. N. Pearce for a praiseworthy collection of varied subjects in different printing. Among them were some very good architectural pictures. Account was also taken, in giving this award, of three of Mr. Pearce's exhibits in the Open Class, *Waiting for the Tide* (platinum), *The Home of the Frog* (Alfieri matt), and *Triforium Arcade, Gloucester Cathedral* (bromide), the first two being specially interesting studies. Mr. Fred Turner, F.R.Hist.Soc., was commended for technically careful work in three silver prints, all of which were of architectural subjects, this being the department of photography in which he takes a special interest. In the same class were exhibits by the Rev. P. C. West, Mr. F. H. Read, and Mr. H. G. Pearce. The President was represented in the "not for competition" class by some very striking pictures, his subjects being gathered from Continental cathedrals. The figures of King Arthur and Theodric, from the tomb of Maximilian at Innsbruck, were particularly good specimens. Mr. F. Hollyer had on view but one picture, a splendid reproduction of J. S. Eland's Academy portrait of Miss Doris Seth-Smith, a beautiful piece of work. The Hon. Secretary (Mr. Hilton Grundy) was also represented in this section with some good work on various subjects, among which should be mentioned his view of Windsor Castle, also *On the Heath*, and *On the Dart*. The Open Class included some splendid contributions from other clubs. The first prize was won by Mr. E. H. Lamb, of the South London Photographic Society, with a splendid platinum picture, *Autumn in the Woods*. Mr. E. G. Boon secured the second silver medal with a picture sent all the way from Italy for competition, called *On the Lagoon* (platinum), and the third prize, a bronze medal, was awarded Mr. W. E. Walker, of the Chiswick Camera Club, for his *Sunset on the Pool*, a Velox print. The same exhibitor was also showing a very good winter scene in bromide. Mr. H. Gentry, of the Chiswick Club, was represented by two very good pictures in bromide, *Autumn* and *Nature's Carpet*. Mr. G. J. T. Walford's *Close of a Stormy Day* was also a splendid picture, and Mr. G. Fryer's collection included some striking carbon pictures.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
27.	Beverley .....	Rambles in Yorkshire. T. J. Morley.
27.	Bradford Photo. Society .....	Annual Dinner.
27.	Camera Club .....	Experiments in Stereoscopic Projection with the Single Lantern. J. H. Knight.—Demonstration of Working Gravura Paper.
27.	Kingston-on-Thames .....	Exhibition of Members' Lantern Slides.
27.	Oxford Camera Club .....	Prize Slides.
27.	Richmond .....	Practical Notes on Outdoor Work with the Camera. Rev. A. H. Blake, M.A.
28.	Birmingham Photo. Society ..	Demonstration: Gum bichromate Process. W. J. Warren.
28.	Hackney .....	With Cycle and Camera. Dr. Roland Smith.
28.	Leeds Photo. Society .....	Some New Points in Platinotype Printing. Rev. J. Beauland, M.A.
28.	Newcastle-on-Tyne .....	Special Stereoscopic Meeting. J. Hedley Robinson.
28.	Royal Photographic Society ..	Ozotype with Carbon Tissue: a New Method of Pigment Printing. T. Manley.
28.	Shropshire .....	Exhibition of Professor Ives's Kromeskop.
29.	Oroydon Camera Club .....	Practical Points on Developing and Printing. A. Horsley Hinton.
29.	Leeds Camera Club .....	Lantern Night. The Members.
29.	Photographic Club .....	Leicester and Neighbourhood. H. Vivian Hyde.
30.	Bolton Mutual Photo. Society ..	Open Night.
30.	Leigh .....	Prize Prints.
30.	Oldham .....	Valley of Conyway. A. Marcroft.
31.	Oroydon Camera Club .....	Whole-day Excursion.
31-April 4	South London .....	Easter Excursion.
31.	West London .....	A Tour Among the Southern Alps. G. Lamley and H. Selby.

### ROYAL PHOTOGRAPHIC SOCIETY.

MARCH 21.—Photo-mechanical Meeting,—the Rev. F. C. Lambert, M.A., in the chair.

#### CURIOUS PHENOMENON IN PHOTO-ETCHING.

Colonel WATERHOUSE (Hon. Secretary) exhibited some prints which had been sent to him by Mr. Turner, who was formerly his assistant in the Photographic Office of the Survey of India Department, at Calcutta, and who is still there, and which showed a curious effect of reversed etching in the heliogravure process. The plate had been developed during very dry weather, and dried

with spirits, and when put into a solution of perchloride of iron (44° Beaumé) there was no sign of action in the shadows for fully five minutes, and the perchloride then suddenly attacked the high lights instead of the shadows. This action continued until about two-thirds of the image was etched in reverse, when an action commenced in the deepest shadows, the result being very nearly a reversal of the image in the print. Another plate of the same subject, etched with the same solutions two days later, when there was more moisture in the atmosphere, behaved quite normally. It was suggested that the gelatine film of the first plate was so dry that the thin film in the shadows formed a sufficient resist to the strong solution of perchloride, whereas the thick film of gelatine, due to its natural attraction for moisture, absorbed what water there was in the solution and carried with it a certain quantity of the perchloride. Colonel Waterhouse also showed some very good experimental three-colour prints by Mr. Turner.

#### AUTOMATIC ADJUSTMENT OF THE HALF-TONE SCREEN.

Mr. W. GAMBLE read a paper with the above title, the object of which was to show that, in half-tone negative-making, as the distance of the screen should bear a constant proportion to the focal extension of the camera, it was quite possible to automatically secure the necessary distancing without any calculation or guesswork. He thought it must be obvious, to every one who had given any consideration to the principle of the process, that there must be a fundamental law underlying it, and there appeared to be no reason why formula should not be provided by means of which the thoughtful man might work with accuracy and directness in every given case, no matter what lens, camera, screen, or copy, had to be dealt with. Further, if the process could be governed by a constant law, means might be devised for achieving automatically by some mechanism the same end that had hitherto only been attained by the exercise of human thought, skill, and ingenuity. The fundamental formula for the half-tone process which the author of the paper put forward was that worked by Mr. Branfill in preparing a series of tables of screen distances, namely, the screen distance ( $x$ ) is to the camera extension ( $f$ ) as the screen opening ( $s$ ) is to the lens aperture ( $a$ ); or  $x = f \times \frac{s}{a}$ . Then, if  $f = 20$  inches,  $s = \frac{1}{100}$  inch for a 100 line screen,  $a = \frac{1}{2}$  in. stop, the screen distance would be  $\frac{1}{2}$  in.; as the camera was extended to 20 in., there would be a distance of  $\frac{1}{100}$  in. for each inch the focus was extended. Assuming this formula to be reliable, it would be possible to obtain the screen distance by automatic means, and it became merely a mechanical problem to decide how to make the screen move  $\frac{1}{100}$  in. when the lens moved 1 in. Different methods of securing the necessary movement were considered, and it was proposed that one definite size of stop should be selected for each screen ruling, in which case the adjustment of the screen could be made mechanically by connecting the screen-adjustment gear to the focussing screw, and introducing a differential motion, so that, when the focus was extended one inch, the screen gear would advance, say,  $\frac{1}{100}$  in., or in any other ratio which might be determined upon. Mr. Gamble said he did not expect the average worker of to-day would take kindly to his idea, for the world's workers had always fought against anything which performed automatically that which had before needed human control; and he concluded by quoting the following sentences from a recent article by Mr. Hall Caine on his tour in America: "One thing which strikes the most ignorant traveller in America is the intelligent attitude of the American workman towards automatic machinery. So far from being afraid of it, he welcomes it. The English workman, on the other hand, appears to discourage and suppress it. It would seem to me that the American workman is fighting *with*, whilst the English workman is fighting *against*, a very clear law of nature, and that sooner or later the trade of the world will be to him who uses every help that nature gives him."

Mr. LASCELLES said he had for the past nine months been working in a similar direction to Mr. Gamble; he was certain the idea could be brought to a successful issue, and it would be of infinite value to half-tone workers. If a camera with this attachment cost an extra 20%, he would expect it to save 50% worth of labour in the first year that it was used.

A brief general conversation ensued.

#### COMING EVENTS.

March 28, Technical Meeting. "Ozotype with Carbon Tissue: a New Method of Pigment Printing," by Mr. T. Manley. April 11, Ordinary Meeting. "The Correct Exposures to be given to Photographs of the Corona," by Mr. E. W. Maunders.

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 16.—Mr. J. S. Teape in the chair.

A short discussion took place on the question of the correct procedure in copying an old painting in which the delicate details had all gone to about the same shade of yellow. The particular example referred to was one of Turner's pictures in the National Gallery. A yellow-sensitive plate, used with a yellow screen, was recommended, the depth of the latter depending upon the actual condition of the original, and only determinable by experiment.

Mr. T. E. Freshwater exhibited, by means of the optical lantern, some forty slides illustrating Chinese types and scenery. They were the work of an official in connexion with one of the English missions, and as such were deserving of commendation, presenting as they did some characteristic portraits of private life in China, the soldiery, &c.

Mr. LEWIS MEDLAND showed a further instalment of his photographs in the northern capitals of Europe, namely, St. Petersburg and Moscow. The account of his successful endeavours in evading the arm of the law in the neighbourhood of the Kronstadt forts, of which he had several pictures, was listened to with interest, and the whole series, of a country by no means overdone photographically, being a little out of the track of ordinary tourists, was very well received. Mr. Medland said the pictures were some twelve years old, and, referring to the slides themselves, said they were all made by the collodio-bromide process.

## PHOTOGRAPHIC CLUB.

MARCH 15.—Mr. E. W. Foxlee in the chair.

Mr. W. R. STRETTON showed one of the negatives reduced with persulphate of ammonium to which he had referred on another occasion, and in which he had been troubled with considerable stain, the gelatine itself being affected. Others he had showed the effect of the persulphate upon intensified negatives in the production of what he styled a fine selection of coloured muds. He could not accept the plea that imperfect fixing of the negative was at the bottom of it, and, although such a state of things might encourage the stain, it was evident that other factors entered into the question.

Mr. G. W. TOTTEM, however, remarked that simply long fixing meant nothing necessarily. He had met with cases where plates which had been left in a stagnant bath for a very long time were removed and found to be quite imperfectly fixed.

Mr. T. SKELTON (of Messrs Elliott & Son, of Barnet) gave a demonstration, intended for beginners, in the carbon process. He showed a piece of plain carbon tissue, and went through the operations of sensitising in bichromate. From the sensitising bath the tissue is placed on a zinc plate, and the surplus solution removed by passing a squeegee over the back of the tissue, leaving it with a nice, even surface. This, when dried, is exposed under a suitable negative in quite the usual manner, with the ordinary pressure frame. There is a slight difference, in that it is necessary to have round the edges of the negative what is known as a safe-edge, a narrow band of opaque material or varnish, so that the picture may be surrounded by a band of tissue unacted upon by light. For a half-plate negative a band of one-eighth of an inch is usually sufficient. The printing is not judged in the usual way, for the reason that light action does not manifest itself by a colourific change in the tissue, and recourse must be made for guidance in this respect to a small instrument known as an actinometer. Mr. Skelton passed round Johnson's form, but there are several which may be employed. The principle of the thing is that, having found the relative sensitiveness of the tissue and the strip of P.O.P. or other paper used in the actinometer, it becomes possible to decide that a certain negative requires so many times the period taken by the silver paper, and so we give the number of tints required. There are two forms of carbon printing—single and double transfer. For the double transfer a plate of ground opal is prepared with French chalk. It then receives a coating of dilute enamel collodion (one in three), and after this is set, but before it is dry, the plate is immersed into plain water, where it remains until the surface ceases to repel the water, in other words, until the remaining solvent has disappeared. The plate is then in a condition to receive the piece of printed tissue. This latter is first soaked in water, not for so long that it will take up all the moisture it is capable of doing, but, generally, until it flattens out in the tank of water. Ordinarily the tissue is squeegeed on to the plate, but, if properly set about, it is no more difficult to apply the tissue without the aid of the squeegee, and be sure that it is free of air balls, than it is to do it with the squeegee. Mr. Skelton preferred to do it without the squeegee's help, and said, moreover, that this removed a possible source of injury to the wet tissue. The only drawback about it was that a longer time was required before the print was ready to be developed, holding as it does a larger quantity of water, which the squeegeed print does not. While these prints, then, were draining, the lecturer took up the single-transfer process, touching in his remarks upon attempts to reduce the double transfers to a single without reversal of the picture, whether by the use of a mirror, by reversing the negative, or by printing through the glass. Taking some pieces of prepared etching paper as the final support, and pointing out the importance, in the case of rough papers, that the air should be thoroughly expelled in bringing the tissue and paper into contact, he proceeded to soak and squeegee the transfer paper and printed tissue in much the same manner as previously described. Development is effected by the use of hot water of an average temperature of 105° Fahr., and is really a washing-out process, the gelatine and pigment unacted upon by light remaining soluble and yielding to the warm water. The demonstrator showed the operations, having the printed tissue with the water, as a result the pigmented gelatine soon commencing to run. Before long the image will be plainly visible, and, as soon as it is judged that development is complete, the combined solution, or "bleeding" of the gelatine, may be stopped by immersion in alum. Time did not allow of the double-transfer prints developed at the meeting being transferred to their final supports, owing to the necessity that they should be dried between the operations of development and final transfer, but prints developed and transferred on another occasion were stripped, the methods involved being described. Mr. Skelton kindly answered a number of questions of detail, and a hearty vote of thanks was passed to him and Messrs. Elliott & Son for the demonstration.

## FORTHCOMING EXHIBITIONS.

1899.

March 24–May 13 ... National Trades and Industrial Exhibition, Bingley Hall, Birmingham. Manager, Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.  
 April 3, 4 ..... Beverley. T. J. Morley, Toll Gavel, Beverley.  
 „ 12, 13 ..... Plymouth Photographic Society. Hon. Secretary, W. H. Harris, 91, Cobourg-street, Plymouth.

## Patent News.

The following applications for Patents were made between March 6 and March 11, 1899:—

DAYLIGHT CHANGING.—No. 4851. "Improvements in Method, Means, and Apparatus for Loading and Unloading Cameras and Plate-holders with Sensitive Photographic Plates and Films without having recourse to a Dark Room." A. B. JOHNSTON and J. E. HENDERSON.

COLLAPSIBLE DARK ROOMS.—No. 4978. "Improvements in or relating to Collapsible Dark Rooms for Photographic purposes." A. E. ANDERSON and the "X" CHAIR PATENTS COMPANY, LIMITED.

CAMERAS.—No. 5235. "Improvements in and relating to Photographic Cameras." C. S. LUMLEY, T. K. BARNARD, and F. GOWENLOCK.

PRINT-EXPOSURE INDICATOR.—No. 5281. "Improved Device for Indicating Exposure of Photographic Prints." J. C. S. MACKINTOSH.

VIGNETTING.—No. 5386. "A Device for producing Vignettes in Copying Pictures and the like by Photography." W. J. HOLT.

TWIN LENS CAMERA.—No. 5396. "New Twin Photographic Apparatus." Complete specification. M. CONSTAN.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

## THE GLOUCESTER CONVENTION.

To the EDITORS.

GENTLEMEN,—Several circulars having reference to the forthcoming meeting at Gloucester having been returned, marked "gone away," I shall be glad if you will allow me to inform any members who may have removed since last meeting, that I shall feel obliged if they will favour me with their present address.

I need scarcely say I shall be pleased to send a "programme of arrangements" to any of your readers who may desire it. Thanking you  
 F. A. BRIDGE

East Lodge, Dalston lane, London, N.E. (Hon. Sec. and Treas.)

March 20, 1899.

## ROLLABLE FILMS.

To the EDITORS.

GENTLEMEN,—If "H" and "W. Barry" will refer to your issue of February 10 (p. 84), also of March 3 (p. 134), they will find that their wants are likely to be supplied in the near future. A reference also to your reply to myself in March 3 will also, I presume, bring the matter up to date, as, so far, I do not see the new rolling film advertised.

I quite agree with W. Barry that the stripping films issued by the Eastman Company gave splendid results, and I am looking forward to being able to procure the Secco films, because I hope to find them of equal quality, and they will be so useful for carbon work, single transfer being all that will be required, as they can be printed from either side.—  
 I am, yours, &c.,  
 E. H. MICKLEWOOD.

5, St. Michael's-terrace, Plymouth.

To the EDITORS.

GENTLEMEN,—In reference to the above subject, I beg to corroborate Mr. Barry's statements in your last issue. It has for a long time been a matter of great regret to me and to many of my friends that the Eastman Company no longer make the paper film, which they used to before celluloid came into fashion. Some of the best negatives I have ever taken were on these paper films, both stripping and non-stripping, in a roll-holder, and the film was in every way more easy to manipulate than the celluloid film now manufactured by them. About two years ago I wrote to Messrs. Eastman, asking them if they could not see their way to putting such a negative paper on the market again, but they replied that they could not, for they did not consider that there would be sufficient demand for it. I think they were wrong in this supposition. Two or three days since, when putting my dark room in order, I came across a portion of a roll of paper film, which I laid by in the year 1899 (about the time it ceased to be made). To test its present condition, I exposed a portion of it in my garden and immediately developed it. I was much astonished to get so good a result on paper which had been carelessly knocking about my dark room for ten years, subject to very varying atmospheric conditions. I enclose you the negative for your inspection, and I think you will agree with me that it is a very fair negative to get under the adverse circumstances.

Could you not, Sir, use your powerful influence to induce the Eastman Company, or some other manufacturers, to place within our reach once more so excellent a negative paper? It would be a "sweet boon" that many would be grateful for.

There are, I know, one or two firms who make a negative paper, but, having tried these papers, I confess they are not satisfactory. They show the grain of the paper, and are not quick enough for instantaneous work.—I am, yours, &c.,  
 A. M. MACDONALD.

Halton, Hastings.

[We believe that Messrs Wellington & Ward, of Elstree, intend shortly placing on the market a rollable film answering to the requirements laid down by our correspondents.—EDS.]

## THE FOCAL LENGTH OF A LENS.

To the Editors.

GENTLEMEN,—If I ask you to give me room for a reply to Mr. Dallmeyer's letter in your issue of the 10th, it is not from any desire to discuss the merits of his solution of the problem which we both of us desire to advance, but because I think that he has hardly appreciated the conditions under which it is sometimes desirable to obtain the focus of a lens.

It is easy to see that there are cases where the solution which is proposed cannot be carried out: in many hand cameras it would be impracticable, and even in many others it would be very difficult; nor is the measurement quite so easy as he supposes, and it is still less easy to formulate all the procedure in terms so simple as to ensure that the ordinary photographer may be able to make use of it.

In his original communication to you, Mr. Dallmeyer truly said that what the photographer wants is the knowledge of the focal length of his lens and the place of the *front focal point*, which involves the position of the front nodal plane, from which the enlarger should measure. Why, then, is it that opticians do not give these data? We get sections of the lenses, sometimes we get the curves for certain assumed indices of refraction and dispersion; these are interesting to opticians, and might aid those who make colourable imitations of the lenses, but to the working man they are no use. The optician *knows* what would be useful to him, and gives him something else which is of no value!

But, in fact, the knowledge of the focal length of a lens (approximately) is wanted by a photographer for other reasons. A good many lenses are in use which have no proper system of diaphragms, and when they are supposed to be numbered by rule some blunder has been made. I can speak from my own experience. Some time ago I had in use a borrowed camera; it was furnished with a good rectilinear lens and an iris diaphragm. I soon found that the numbering of the diaphragm was incorrect; and, moreover, that the openings were not even in the proportion which they purported to bear to each other. The lens, too, was so attached to the camera that I could not readily disconnect it. Not being of the persons who expose a second with the smallest possible stop, I proceeded to determine the focal length of the lens, and measure the diameter of the various openings of the diaphragm; but I could only have done this by the second method I gave, a method which is universally applicable, if not as accurate as that which has been under discussion.

Let me say in conclusion that I have tried this method, got over the difficulties which offered themselves, and can vouch for it that in careful hands it is very accurate; but the use of it has confirmed me in the opinion that there are a variety of conditions required for its successful application which cannot always be attained.—I am, yours, &c.,

J. F. T.

## COLOUR FALLACIES.

To the Editors.

GENTLEMEN,—In an article in THE BRITISH JOURNAL OF PHOTOGRAPHY of February 24 last, on the above subject, you utterly condemn Mr. R. Hitchcock's theories. Some eight or ten years ago I amused myself with attempts to get photographs in colours, and, from my experiments, came very nearly to the same conclusions as Mr. R. Hitchcock, viz.:—

1st. That colours of an object do impress themselves on an orthochromatic photographic plate, and that the specific effect is retained in the negative.

2nd. That a print from such a negative is also specifically impressed by the colours of the original object.

(b.) The positive print may manifest selective action in the developing and toning solutions, and that thereby the colours of the original object may be more or less correctly reproduced.

My reasons for so thinking and agreeing with Mr. Hitchcock to the above extent are:—

1st. That, in printing on special paper, with special developer and toning solution, I have, to a certain extent, been able to differentiate colours in the prints from an orthochromatic plate which I could not get with an ordinary plate.

2nd. That I could always, more or less, get the same approach to colours each time from the same plate, but not from another orthochromatic plate, exposed at the same time, at the same view, the one being in appearance the counterpart of the other, the exposure and development being the same in each case apparently.

Hoping you will find room in your paper for the above protest,—I am, yours, &c.,

WM. R. O'HARA.

West Lodge, Galway, March 18, 1899.

[The theory we condemned implied that negatives on ordinary plates recorded and transmitted colour; and we still condemn it as absurd. We are much interested in Colonel O'Hara's experiments with orthochromatic plates, and special developing and toning solutions, and should be glad to have further particulars. But, frankly, we are sceptical of such a method having the least value in the reproduction of colour. It fulfils none of the requirements of current theory.—EDS]

## NORMANDY.

To the Editors.

GENTLEMEN,—In response to your invitation to give information about Normandy in the sense expressed by your correspondent in your number of the 3rd inst. (p. 143), the best suggestion I can make—a suggestion which is supported by many years' residence in the country—is that he should follow Major C. Gardner Vatcher's itinerary, as laid down in the article from him you have published in this year's ALMANAC (p. 793). Nothing could be so practical and complete. If more details are wanted by your correspondent about the towns and localities mentioned by Major Gardner Vatcher, Baedeker's *Guide to the North of France* will furnish them with great accuracy.—I am, yours, &c.,

GEORGE FERNAU.

Bellvue, Montvireon par Sartilly, Manche, France, March 19, 1899.

## SPECIMENS.

To the Editors.

GENTLEMEN,—May I trouble you to give me space in your next issue to thank Mr. Gain for his very able letter on this subject, so exactly does it describe my own views, and also to reply to the letter signed "Professional?"

One might easily imagine "Professional" to be "H 21," 24, Wellington-street, so bravely does he take up the cudgels on behalf of the practice of exhibiting "attractive specimens" of other people's work as his own.

I can very easily pass over the sarcastic remarks about amateur editors, &c., as also the best part of the next paragraph, as not having the slightest bearing on the case. But "Professional" wants to know how to obtain a "few specimens of a certain style to complete a fair representation," but he forgets to say of what. Does he want to exhibit a fair representation of *his own* or another person's work? If the former, Mr. Gain gives him a very simple answer; and, if the latter, doubtless some brother "professional" would oblige him with a selection of "attractive cabinet specimens for show-case," but, of course, they wouldn't be "unmounted." "Professional" may try and smother his conscience by saying the "output equals the specimens" he bought, but that doesn't in the slightest degree lessen the deceit; for any man who buys specimens "unmounted" and finishes them on his own mounts, and exhibits them to the public as his own work, is a living fraud, and should be known as such. If "Professional" is "H 21," and this system is right and honourable, as he tries to make out, may I suggest to him that it would be well to disclose his identity? It doesn't seem quite right for "Professional" to defend a certain system, and not have the courage to sign his name.—I am, yours, &c.,

HARRY FRENCH.

1, Railway terrace, Wallington, March 18, 1899.

## To the Editors.

GENTLEMEN,—With reference to the many correspondents who suffer because their specimens and photographs of themselves are either seized by the unscrupulous advertisers or kept back because they are too lazy to return them, I think they (the applicants for situations) have just cause for speaking out. Specimens have to be got from somewhere by these assistants, and it is a most unjust act for any photographer to retain them.

I don't suppose one-half or perhaps a quarter of them are retained because of their value to the photographer, but that is far from an excuse for not returning the same. Again, I do not think it argues very well for photographers as a body to demand seeing specimens of an assistant. Logically or practically, an assistant is not going to send any of his *inferior* work, and he is not going to be quite so immaculate as to refuse a print or negative specimen solely because he did not make it himself. Many specimens are, undoubtedly, sent on to a photographer that could not be reproduced by the assistant. Do photographers *know* this, or do they care? "Cosmos," in his Jottings this week, has a very open remark *re* assistants (see Jotting No. 8), in which he sums up by saying, "A professional photographer is very much like other business men; he knows good work and good men when he sees them," &c. There is no doubt he does *sometimes*. There are good photographers and medium photographers, and photographers who are not good and not medium, and all photographers are not "business men," and many assistants who are not good workmen are "business men," and so I am led to think "Cosmos" has scarcely touched the fringe of the subject, and there are hundreds of assistants who are certainly suffering an injustice, and will continue to do so until something can be done.

In a letter by W. A. Kidd, in your Correspondence this week, he says, "I concur with 'A. A.' in his letter. It is not a first-class assistant that is required nowadays, but perhaps it would be better to term them dabblers. A first-class assistant gets what I call insulted," and "from 1l. 10s. per week to take sole charge," &c. Now, there is a great deal of truth in this, but there are really good houses, Sir, who must have a first-class printer; for instance, he must know everything in printing and have been in the best houses in the trade, and 1l. 10s. is the magnificent offer—one has just offered 1l. 15s. to a friend of mine, but this was a place where "the best only" is turned out.

No doubt something could be done by having a department in connexion with the various local institutes, where examinations could be held and where certificates could be given which would permit assistants to qualify for good houses, copies of such certificates being sufficient as to a man's abilities.

Specimens would then be a useless item, and deceiving assistants—I should say *business* assistants—would be obliged to "cave in."

With deep apologies for such intrusion on your valuable space,—I am, yours, &c.,  
F. G. WILLIATT.  
101A, Fulham Palace-road, Hammersmith, W., March 20, 1899.

## OPERATORS AND AGREEMENTS.

To the Editors.

GENTLEMEN,—I am glad your correspondent gives publicity to this matter, as these agreements are becoming quite common, and I think operators ought to combine against this kind of thing, which is likely to become a nuisance, and is calculated to create in time an unhealthy feeling between employer and employee.

It is all very well, in some cases, where operators are handsomely paid for signing such agreements, but a salary of 8l. 10s. per week for a first-class man and the signing of such an agreement is simply absurd, and "Operator" has done quite right in exposing the case as a warning to others.

I dare say there are many more operators who wish they could afford to follow his example.

I consider agreements of such a nature want well paying for.—I am, yours, &c.,  
ANOTHER OPERATOR.  
March 14, 1899.

## THE LEEDS CAMERA CLUB AND THE YORKSHIRE PHOTOGRAPHIC UNION.

To the Editors.

GENTLEMEN,—I am sorry that my friend, Mr. Warren, seems to be losing his temper in the letter published in last week's issue.

Sarcasm, however clever, is not argument, and the latter is conspicuous by its absence throughout the whole of that effusion. To ignore an opponent's arguments and attack him personally may be 'cute policy, but, in my opinion, it is questionable taste, and, to use Mr. Warren's own words, *playing the game too low*.

The air of injured innocence, and the excuse that in attacking the Union Mr. Warren was justifying the position of his Club, are simply convulsing. If the Federation of Societies offers no advantages to, say, the Leeds Camera Club, surely that is no reason why its President should take up a hostile attitude and attack an organization the constitution and aims of which he does not even take the trouble to understand.

I have not attacked the Leeds Camera Club, nor should I think of attacking any club; let each do the best it can for its own interests. As a delegate of the Union, I cannot allow even the President of the Leeds Camera Club to build up beautiful theories on false premises in order to bolster up an illogical position.

In conclusion, I think I may fairly claim that my opponent has been compelled to lower his colours, and the fact that he has run away from all argument is proof that the reasons adduced for the action taken by the Leeds Camera Club are like unto a well-known soap, which has certain merits, but *won't wash*—clothes. Thanking you in anticipation, —I am, yours, &c.,  
EZRA CLOUGH.

13, Chesham-street, Bradford, March 20, 1899.

## ANIMATED PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—I notice in the Correspondence column of your last issue a letter signed "W. Barry" relating to the very tardy recognition of the name of Friese-Greene as a pioneer of animated photography, at the same time hitting out pretty hard against other so-called "inventors."

Now, so far as Mr. Friese-Greene's share of invention of animated photography is concerned, I have on every occasion when delivering a lecture on animated photography (and I have given several dozens extending over more than three years) distinctly named Mr. Friese-Greene's work.

So far as invention is concerned or the original inventor, it is exceedingly difficult to fix on a name. Personally I regard the matter as one of evolution, from the zoetrope. It will be in the recollection of some of your readers that, at the Royal Photographic Society's Exhibition in 1892, I exhibited a series of enlargements entitled "The Story of a Cloud," which illustrated the movements of a cloud, but in this case a comparatively long interval is shown between each picture; but these photographs were really taken with an apparatus for bringing a number of plates  $3\frac{1}{2} \times 3\frac{1}{2}$  in rapid succession behind one lens, my previous efforts with twelve lenses not giving satisfactory results, due to the shortness of the interval and the serious defect of parallax, as explained in my paper read before the Royal Photographic Society last month.

I presented this "Story of a Cloud" to the Royal Photographic Society's Permanent Collection, and it is now on tour, I believe, with the Affiliation-scheme lectures. The prints are carbon enlargements.

I only quote this to show that I, at least, was at work on this subject years before the present boom, and, although I have had the mortification of seeing my work exploited by others, still I have the satisfaction of knowing that I had not stolen ideas from any one.

Apologising for trespassing on your valuable space,—I am, yours, &c.,  
BIRT ACRES.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

H. M. Whitlock, 319, High-street, West Bromwich.—Photograph of Ruben Farley, Esq.

T. M. Lund, 27, Bridge-street, Kelso, N.B.—Photograph of Charles Rutherford, King of the Gipsies.

T. H. Smelt, Cypress House, Victoria-road, Fleet, Hants.—Cabinet Photograph of W. W. Bruce, Esq., 4, Copthall-buildings, London, E.C., champion croquet player, gold medalist.

F. Coghlan, 31, Carlisle-road, Londonderry.—Two photographs of the Very Rev. Charles McFaul, P.P., Water-side, Londonderry:—1. Cabinet vignette without glasses. 2. Vignette with glasses on.

ELEANOR FIELD (Maidstone).—Sorry we cannot supply such a list. The paper to which you refer is chiefly used by architects and engineers.

J. P. MARSHALL (Buddleigh-Salterton).—If the sitters paid for the photographs, the copyright is theirs, unless it has been assigned to the photographer.

P. R. S.—It would be quite practicable, we think. The material would be found in the British Museum (prints), the Record Office (documents); the Herald's College, &c.

A CHINESE SUBSCRIBER.—Messrs. G. Houghton & Son, 89, High Holborn, and Messrs. W. Watson & Sons, 313, High Holborn, London, W.C., would send you particulars of such cameras.

EMULSION-MAKING.—A. BAKER says: "1. Kindly tell me how to test gelatine for alum. 2. Will potassium bromide that contains potassium chloride give fog in bromide emulsion?—1. There is no simple and reliable test for alum in gelatine. 2. No.

STRETCHING PRINTS.—R. L. E. says: "Please tell me what would be likely to stretch P.O.P., when toned and fixed, without injury to the print."—We know of nothing that would be likely to stretch the paper beyond its normal expansion while wet, though with force it may be stretched a little beyond that. The gelatine will be stretched with the paper without injury.

Mrs. BLAIR.—We regret your last week's communication was overlooked. Your requirements would be met, we think, by the purchase of a hand camera taking rollable films, but it is against our rules to recommend particular makes. If you will procure THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1899, and study the advertisements, you will find almost every type of modern hand camera described.

G. S. C.—1. Sorry, but we cannot recall such a publication. 2. Yes; the focus may be shortened in the manner described, and the results, if the work is not of a very critical character, would be passable; but you would require to cut the mount and experiment with a number of double convex glasses of different powers. We, however, do not advise you thus to interfere with the lens. Better purchase a wide-angle lens outright.

LENS.—R. KIRK. The lens, if it has no name upon the mount, is certainly not by Dallmeyer, whatever you have been told. From the description, we should say it is a French portrait lens of the ordinary type. It may, however, be a very good instrument, but it is of little value commercially, probably under twenty shillings. Plenty of second-hand half-plate French lenses are to be had for even less than that sum, and some of them may be very good.

SILVER STAINS.—L. & J. say: "We should feel greatly obliged if you could inform us what we might do with negative that is covered with silver spots? Having been printed unvarnished during the damp season, the silver from paper has entered the film, making one mass of white spot on present print."—Try the effect of a weak solution of cyanide of potassium. That is the best thing we can suggest, for there is really no satisfactory method of removing these spots if they have been on the film for some time.

LENS FOR HAND CAMERA.—C. BAKER says: "I am desirous of making a half-plate hand camera, but think that, owing to the focal length of ordinary rapid rectilinear lenses, it would make an extraordinary large affair. Would it be possible to use a wide-angle rapid rectilinear in a hand camera? The approximate focus of an ordinary rapid rectilinear is (half-plate) 7 to 8½ inches, and a wide-angle 4½ to nearly 5 inches. The question I should like answered is, Can I use a wide-angle lens in a hand camera for exactly the same sort of work that an ordinary lens is used for?"—In reply: By selecting one of the modern anastigmats a half-plate hand camera can be constructed to take 6½-inch lens, which at f-11 or f-16 will cover the size of plate named. For a quarter-plate camera the lens may be used at full aperture.

**VALUE OF A BUSINESS.**—**SATISFIED** asks: "Will you please inform me how a valuation of a good photographic business is arrived at? Returns, about 900*l.* per annum; rent, 45 guineas; wages list (exclusive of self), 2*l.* 17*s.* 6*d.* weekly; good prices obtained. What sum do you think such a business should sell for?"—In reply: The business must be valued by the net profits, not by the returns. It is obvious that a business with high prices shows a much larger profit than one with medium or low prices. Much also depends upon the opposition in the neighbourhood, as well as the neighbourhood itself—whether an improving one or not.

**SALE OF PHOTOGRAPHIC CHEMICALS.**—**CHEMICALS** says: "I should be glad if you would advise me on the following question: I wish to add a photographic branch to my business, but do not know how far I can go in the sale of chemicals? Could I sell pyro in the ounce bottles, hydroquinone, amitol, and suchlike developers, and could I sell a ready-made developer containing the above chemicals also a ready-made toning solution containing sulphocyanide of ammonium?"—In reply: We take it our correspondent wishes to know his position with regard to the sale of poisons. Let him consult the Poisons Act given in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1899 and he will there see what substances he is (legally) precluded from vending.

**STUDIO BUILDING.**—**F. W. GIBSON** says: "I am exceedingly obliged to you for your reply in last week's issue (March 17). I find out that I can have only 12 feet length by 12 feet breadth for studio construction. Do you think the length is too short for studio work? Also, would a six-inch focus lens be suitable for that length? Would the lens do for groups and full-length cabinet portraits. Last week I asked you how much top light and side light I should require."—Unless you can have a greater length, we should say, Do not build the studio at all, that is, if it is wanted for professional work. The shortest-focus portrait lenses that are made for cabinet and *carte* pictures require from 12 to 13 feet between sitters and lens for full-length figure, and, of course, a still greater length would be required for full-length groups.

**STUDIO BUILDING.**—**LUCERN** says: "I am about to erect a photographic studio, would you kindly answer following: Studio will be 28×15 ft., and have a northern exposure with glass as per sketch; (1) would it give better results in lighting to have top portion clear instead of ground glass? 2. Would white or dark green curtains be better? 3. What would be best colour to paint interior walls? 4. There will be a foot taken off front of studio by a chimney stack as in plan, will that affect light? P.S.—The stack has been lowered to two feet, and chimneys carried up by pipes; but what I wish to know is, will altered plane of the glass affect lighting?"—1. No. 2. We should prefer a rather light green. 3. A pale green and French grey, or any quiet colour that will not try the eyes of the sitter. 4. It will not make a serious difference, though it would be better were it not there.

**LENSES AND PANORAMIC PHOTOGRAPHY.**—**F. V.** says: "Would you kindly inform me what kind of lens would be the best for me to buy? I wish to take some half-plate negatives (landscapes), but I want to get the image as large as possible and less angle of view with as much equality of illumination as is possible, and I want it to cover the plate right sharp up to the edge of the plate. My camera will rack out to fifteen inches. I also want to take a panoramic view. Would you please tell me where I could obtain some information on panoramic photography, as to what lens to use?"—Get a long focus lens—say twelve to fourteen inches, as the camera will extend to fifteen inches. If the lens be used exclusively for landscape work, a single lens will answer quite well, but for general all-round work a rectilinear will be preferable. Several pages are devoted to panoramic photography (by different methods) in the ALMANAC for 1892.

**TEMPORARY SUPPORTS; FIXING ALBUMEN PRINTS.**—**TEMPORARY SUPPORTS** asks: "Could you tell me, (1) What was the cause of a carbon stripping from the 'temporary support'? It was developed, &c., in the usual manner and was hung up in the developing room (which was very steamy and damp), and the next morning it came off; there were others done at the same time which were all right. (2) If albumen prints after fixing were passed through hot water (to get the hypo out of them sooner), would this injure them in any way or alter the tone?"—1. Over-drying the prints might cause the spontaneous stripping, but that would scarcely be the case in this instance, seeing that others did not come off. Possibly in the one case there was too much of the waxing compound left upon the support, or that the solvents had not thoroughly evaporated before the tissue was squeegeed upon it. 2. Not if the prints were well toned with gold, unless, indeed, the water was used unduly hot.

**DETENTION OF SPECIMENS.**—**ASSISTANT** says: "I have read with interest in your paper one or two letters from assistants who seem to be in the same box as myself. Like your other correspondents, I answer three or four advertisements every week, and am getting quite used to receiving no replies. I begin to think, like others, that either the trade is overcrowded or the advertisers are humbugs. The unkindest cut of all is the following, and I should be pleased if you could give me any advice. In your issue of February 24, I saw an advertisement from — for a general assistant, asking for lowest terms, references, specimens, and photograph of self. These I sent, and also stamps for return postage, and from that day to now I have not heard another word from him, although I have written him twice, asking for return of specimens. I consider it a very mean trick to deprive a man of his one means of getting another situation, and should like your advice as to any means of recovering them. I sincerely trust, for the honour of the profession, that there are not many men who would do such a thing, and hope none of your readers have been the victims of these 'humbug' advertisements."—In reply: This seems a hard case. We should think a threat of legal proceedings would result in the return of the specimens.

**CARBON PRINTING.**—**H. WALLACE.** The cause of the tissue refusing to adhere to the single transfer paper, if you have proceeded precisely as you say, is due to the tissue being insoluble. That you can easily test for yourself by placing a piece in water, temperature 100° Fahr. If it does not quickly dissolve, it is no use attempting to use it. If it does dissolve, the fault must be somewhere else; probably it is left too long in the cold water before it is squeegeed on to the transfer paper.

**STUDIO BUILDING.**—**A. FLINT** says: "In building a studio 25 feet×14 feet, glass on north side only, what would be the correct height to eaves and to the ridge? Also what would be the best material for blinds?"—In reply: About 7 feet or 7 feet 6 inches to the eaves, and about 12 feet or a little more to the ridge. As the studio will be lighted entirely from the north, have pale green or a darkish blue for the blinds. Ordinary window holland is as good a material as anything for the purpose.

**LANTERN SCREENS.**—**PHOTOPHYLAX** writes: "I should be very much helped if you would tell me the best way to coat calico for a magic-lantern screen, the main points being (1) opacity; (2) whiteness, and permanence of the whiteness; (3) suppleness, for rolling up. What, amongst the materials obtainable in most places, would form the best mixture for coating the textile? How many coats should be given? To work could would be easier. White paint is expensive, heavy, and turns yellow, and takes long to dry. Lime or chalk seems to crack off, and is also perhaps apt to rot the fabric. Should the calico be stretched before whitening? It would be about five yards long."—We do not know of anything better than white paint, with just a very slight tint of blue with it, for the purpose, all things considered. The Vanguard Company, Maidenhead, supply a material that, no doubt, will answer the purpose. The fabric should be stretched on a frame before the coating (whatever it may be) is applied.

**ANILINE.**—**ANILINE** says: "I have a quantity of the base of aniline, mauve or purple, in dry state; looks like bronze, but, when dissolved in spirit, it is a very rich mauve or purple. Now, if you mix it up with water, it is a very dull colour, no transparency about it, and as though black was added to it, but, the moment dissolved in spirit, it is rich. Can you kindly inform me what I can add to it to make in a liquid form to write with? Spirit would evaporate too soon whilst using. If I recollect right, it is a fact they can prepare aniline dyes either to be dissolved in water to fetch the rich colour or not, and only spirit to fetch out the proper tint."—Some of the aniline colours are soluble in water, and some are not, or only partially so, and we suspect the one in question is of the latter kind. Not knowing, from the description, which particular dye is referred to, we cannot answer the query. Any of those who supply coal-tar colours will supply many of them that are soluble in water alone.

**A MASTER'S GRIEVANCE.**—**A. A.** writes: "I took a young fellow as an apprentice, with not a very large premium, for three years. I have taught him printing—P.O.P., C.C., platinotype, and albumen, toning, mounting, and all that, and he has done all my work in that way for nearly two years. Now his father is complaining that he is not working at taking sitters, and threatening all manner of things. Of course, I cannot have him taking portraits of sitters in the studio, as I did not bargain for that. I only took him as an apprentice to learn photography."—As you undertook to teach the apprentice the trade of a photographer, you must do so, and taking portraits is the most important part in it. We are afraid you are like too many others, who take apprentices, with a premium, merely to get the printing and suchlike done for nominal wages, or none at all, without the intention of really teaching them their trade. However, it is incumbent on you to do so, and you will have to do it or take the consequences—no mean ones—in a court of law.

**CARBON PRINTING.**—**AZAY** says: "Will you kindly give me a hint how to avoid bubbles and blisters in carbon printing on rough-surfaced single transfer paper? I have read Mr. Sawyer's book and Mr. E. J. Wall's book on the process, and carefully done the things advised and left undone the things condemned. Still there are bubbles or blisters on every print made. Some are worse than others, but not one wholly escapes. The paper I have been using is the Autotype Company's toned etching paper, and the thick Whatman drawing paper supplied by the same Company for single transfer. I duly leave the transfer paper in water of the required temperature for the required time before mounting, and I leave the mounted tissue for the required time between blotting paper under heavy weight before developing. I use a scraper squeegee. The bubbles or blisters are not round the edges, or I should conclude a defect in the safe-edge. They are generally about half way towards the centre. I have never had this trouble in the smallest degree with ordinary smooth single-transfer paper, so that the defect, whatever it is, can hardly be traced to the tissue. Giving the same care to the rough paper as to the smooth, the only difference being the longer time of immersion for the transfer paper before mounting, and the longer time after mounting and before development, I get in every rough-paper print some blister or bubble, in no smooth paper print a single one. Can you suggest a reason why?"—The trouble is evidently due to air being imprisoned between the transfer paper and tissue in the squeegeeing. The air, in the first instance, is doubtless in the interstices of the rough paper. See that it is thoroughly removed from these while in the water, by going over the surface with the fingers or a soft piece of sponge then bring the tissue and paper into contact (while under water), and, when removed, apply the squeegee with some force.

\* \* Several answers to correspondents unavoidably held over.

## EX CATHEDRA.

PROBABLY no boat-race day opened more propitiously for photography than did Saturday last. Probably also, on no previous occasion, notwithstanding the cold, were so many hand cameras to be seen along the tow path, or so many cinematograph apparatuses planted at the best points of view. Unfortunately, however, about the time of the start the sky became somewhat cloudy, and for the greater part of the morning brightness disappeared. However, we are given to understand that several very successful cinematograph negatives of the event were secured, though they have scarcely the brilliancy and sparkle they would have had if the sun had retained its morning's brightness at the time they were taken. Mr. Charles Morton, of the Palace Theatre, again showed with what accuracy, rapidity, and clearness the race could be illustrated by the biograph, which at this establishment is always up to date. By night he was quite ready to give a representation of the earlier stage of the contest between the two crews. The picture was taken from the referee's boat, and the excellent result justified the privilege accorded Mr. Morton's artists.

About eleven at night a densely crowded audience, quick to applaud every reference made on the stage to the race, witnessed the start with much more comfort than if they had been standing on the river-banks, and they loudly cheered the boats depicted as struggling through the lumpy water. The picture, we believe, was subsequently added to. A success on the biograph was also achieved on Friday with a picture of the finish of the race for the Grand National.

\* \* \*

IN some cases in the Law Courts Judges have refused to accept photographic portraits as evidence of identification. In other cases they have been admitted as a conclusive proof. Last week, at the inquest on the body of the victim of the Whitfield-street murder, a witness identified it as her sister from a photograph taken after death. The coroner said to the witness that if she had the slightest doubt in the matter he would have the body exhumed at once, but she had not. The jury clearly accepted this photograph as evidence, for in returning their verdict they found that the body was that of the witness's sister; but in this instance the photographic evidence was somewhat corroborated by the deceased's clothing found in the room, which was recognised by the sister. Here is an instance where a photograph taken after death was accepted as conclusive evidence of identity.

\* \* \*

It is not often that a cinematograph accident is considered to be advantageous. A correspondent, however, sends us a cutting from a local paper of the report of the Chiswick Overseers' meeting last week. From that it appears that the vestry hall keeper inquired what the Overseers would do with regard to the letting of the hall for cinematograph shows, as "they were very dangerous, and there was no appliance in the hall for them. They might explode and set the place on fire." The chairman is reported to have replied: "If it was only for the destruction of the hall, I should vote for it." From this it would seem that some persons look upon a cinematograph accident more as a blessing than anything else, when it would lead to the destruction of one hall to make room for a better. In the end, however, the hall keeper was instructed to accept no applications for that class of entertainment, so that there is no immediate prospect of the Chiswick Vestry Hall being destroyed by the cinematograph.

THERE appears very little chance of the Government taking steps to make the metric system compulsory. Mr. Ritchie, President of the Board of Trade, met a deputation last week at the House of Commons, who came to urge upon him the necessity of a compulsory metric system of weights and measures in this country. The deputation was large and thoroughly representative of commerce, science, teaching, and labour. Sir Samuel Montagu, M.P., in introducing the deputation, said what they proposed was that the Board should negotiate with the United States for a simultaneous adoption of the metric system. A permissive Act was of no use; the system must be made compulsory.

\* \* \*

MR. RITCHIE, in replying, said that, in his opinion, the arguments used in favour of the metric system could not be controverted. The great bulk of scientific opinion was on the side of the deputation. But that was not a question which they had to discuss that day. The real question was whether or not the metric system was the more suitable system for the transactions which are carried on all over this country. It had always been legal for scientific research, and in 1897 an Act was passed which made it legal for external trade. Mr. Ritchie said he entirely agreed with Sir Samuel Montagu's views as to the importance of the question to the external trade of the country, and, indeed, it would be impossible to take any other view, and there was no reason why those who deal with foreign merchants should not adopt the metrical system at once. But a suggestion had been made that within two years the system should be made compulsory in the internal trade of the country. He would like to point out that previous deputations had waited upon Ministers, and that in all cases the same reply had been given. Whilst these replies had been sympathetic, Ministers had declined to make the system compulsory in this country. There would be great difficulties in the way of its adoption by the small trader, and the chaos and confusion created by its compulsory adoption would be so great that he feared it would be impossible to carry out the law. He was afraid, therefore, he could not promise to introduce a measure to make the metric system compulsory in this country. Here, therefore, matters must be left, we fear; and future effort it is plain must be concentrated in the direction of securing voluntary adherence to the system.

\* \* \*

ACCORDING to a correspondent of the *Daily Graphic* another place of great historic interest is to be demolished. Sutton Court Estate and house, Chiswick, has recently been sold for building purposes. It is on record that the manor of Sutton was in the possession of the Dean and Chapter of St. Paul's in the reign of the Conqueror, and that the talented lawyer, Challoner Chute, resided there in 1639, and he was succeeded by one of Cromwell's daughters, who lived there for some years. Little of the original house, however, now remains, as it was almost rebuilt during the end of the last century. Still the place as it is now is of historic interest, and those who desire to secure photographs of it should lose no time in obtaining them, or they may be too late. There are many picturesque spots in old Chiswick, but they are fast disappearing at the hands of the speculative builder. Two or three weeks back we referred to the approaching demolition of Kew Bridge and the threatened "improvements" of that picturesque

little spot, Strand-on-the-Green, though up to the present nothing has been done. It is still the happy hunting-ground of artists and some photographers.

\* \* \*

EVIDENTLY the spy scare in France has not subsided, neither is it confined to the frontiers. A Dalziel's Paris telegram of Friday last tells us that three students of the Ecole des Beaux-Arts were arrested at Chars. One of them is an American, and this, together with the fact that all three took a number of photographs, caused them to be suspected. The Mayor ordered them to be arrested, and they were confined for several hours in an uncomfortable lock-up before the village authorities would listen to their explanations. Finally, the mistake was admitted, and the young fellows were released, with profuse apologies for the mistake. We mention this circumstance for the purpose of putting English photographic tourists on their guard while travelling in France, as many may be doing this Easter. It will not be pleasant for them to have their holiday curtailed by several hours' confinement in village lock-ups, which, we understand, are by no means such pleasant quarters as are to be found in a good hotel. Even profuse apologies, when rendered, are not a recompense for the inconvenience suffered or the indignity conferred by several hours' detention in *durance vile*.

\* \* \*

WE have received the Annual Report of the Liverpool Amateur Photographic Association. A glance through the fifty-eight pages of the volume is sufficient to show that the Association, which dates back to the year 1864, is in a very prosperous state, numbering 326 members. In the "list of officers of past years," which is printed in the report, occur the names of many of those who thirty odd years ago made Liverpool perhaps the most important photographic centre in England. The Association has a good library, rents its own rooms, gets through a great deal of useful photographic work in the course of the year, and is at present presided over by the popular Paul Lange. We congratulate the Association on its present proud position, and trust it may long thrive.

\* \* \*

WE are pleased to receive from the Rajputana Stereoscopic Works, Ajmere, a catalogue of stereoscopic views and lantern slides of Indian views. The catalogue extends to a hundred pages, and lists many hundreds of subjects taken in various parts of India, which, of course, supplies a practically illimitable field for stereoscopic work. Those of our readers concerned in stereoscopy may be interested in knowing of the existence of this catalogue, which is prefaced by some remarks on stereoscopic pictures and the stereoscope that are not acknowledged to their source, namely, W. L. Chadwick's *Stereoscopic Manual*.

\* \* \*

THE Directors of Kodak, Limited, have declared an *interim* dividend upon the preference shares at the rate of 6 per cent. per annum for the period ending 31st inst., and the same will be payable on and after April 1 next. The Directors have also declared an *interim* dividend upon the ordinary shares of 2½ per cent. for the quarter ending the 31st inst. (being at the rate of 10 per cent. per annum) and the same will be payable on or about April 1 next.

THE Autotype Company, of 74, New Oxford-street, W., are issuing two little publications relating to carbon printing which will be of the greatest use to all those interested in the making of photographic prints by the pigmentary process. The first of these is *Carbon Printing in the Tropics*, by Colonel J. Waterhouse, I.S.C., in which the author draws upon his unique experiences of photography in India for the purpose of minutely detailing the special conditions which the carbon printer has to deal with in the Tropics. To those who have to work the carbon process in climates where the extremes of temperature and other abnormal natural conditions are encountered, Colonel Waterhouse's valuable notes of his experiences will prove of very great informative use. The second pamphlet which the Autotype Company send us is entitled *First Steps in Autotype Printing*, and it appeals to the beginner in carbon work, who will find it a simply written introductory guide to the process. We can cordially recommend both pamphlets, which are priced respectively sixpence and three-pence.

### THE ACTION OF THE PERSULPHATES ON THE PHOTOGRAPHIC IMAGE.

SINCE the introduction of persulphate of ammonia by MM. Lumière Frères as an agent for reducing negatives, a good deal of mystery seems to have hovered round that and similar substances so far, at least, as regards their action upon the negative image. We say "similar substances" because we are well aware that the recently introduced persulphates, or salts of persulphuric acid, as it pleases some to call them, are said to be of entirely different composition and construction from other so-called persulphates—that of iron for instance, which, as well as the double salts, known as "iron alums," we have used for many years, for reducing or removing the image from collodion films. But an analysis of their relative compositions will, we think, show that for practical purposes, at least, they are identical, and certainly their separate actions do not differ much.

Let us take first of all persulphate of ammonia, which in the dry state is physically totally different from either the acid or the normal sulphates; but, when it is dissolved in water, it undoubtedly decomposes, and there can be little doubt but that the final result is something like this:—

In other words, the persulphate splits up into bisulphate, and sulphuric acid and oxygen are liberated, the latter of which, no doubt, forms hydroxyl with another portion of the water.

Next, look at the composition of ferric sulphate, also formerly called persulphate of iron. The simplest analysis of this formula shows it to consist of two equivalents of ferrous sulphate in combination with one each of sulphuric anhydride and of oxygen; but in solution we have the following equation:—

or, so far as the active constituents for reduction purposes are concerned, precisely similar to persulphate of ammonia. Turning finally to the iron alums, of which we may conveniently take the ammonium salt as the type, more especially as it is at once the most permanent and the most useful, we

do not find any material difference. Leaving out the water of crystallisation, we have

An examination of the latter part of this equation will show that it only differs from the previous one in having an equivalent of neutral ammonium sulphate thrown in as useless ballast and, eliminating the ferrous sulphate, we have the formula for persulphate of ammonium *plus* water. From which it will be gathered that ammonia iron alum, for experimental purposes, may be conveniently made by mixing ferrous sulphate and ammonium persulphate in equivalent proportions.—

and if such a solution be made it will not act differently, either for better or worse, on a collodion plate than one containing the same quantity of persulphate alone.

From a purely photographic point of view, then, it can scarcely be doubted that the action of these three different salts is identical, although chemists may choose to class them differently, and it might be further assumed that the cheaper iron salts were as useful as the newer agent. Such, however, is far from being the case; for, as was pointed out on its first introduction, the special beauty of the ammonium persulphate as an oxidiser and reducer of negatives lay in the fact that its properties were not marred by the formation of any by-products. When some eighteen years ago, at a meeting of the Photographic Club, Mr. Warnerke first introduced ferric sulphate, or, as he then called it, persulphate of iron, as a solvent of silver, great things were expected of it. But it soon turned out that, when applied to a gelatine plate, it stains the film indelibly yellow, and when used, as it was attempted, to remove the developed image before fixing in order to make a reverse negative, it deposits a yellow iron salt in place of the silver removed. These objections do not hold good with regard to collodion plates, and for all purposes where such are concerned the iron persulphate may be used with equal advantage to the ammonium salt.

There seem to be at present insuperable objections to the theory put forward by Messrs. Lumière to explain the special reducing action of persulphate of ammonia; but two facts seem to be beyond doubt, namely, that the solution possesses a reducing action upon salts of silver as well as a solvent action on the metal itself. The same occurs with the iron salts mentioned; if silver be dissolved, it is in a short time precipitated in a beautifully fine powder, in the case of ferric sulphate of a brilliant whiteness almost equalling the polished metal. The two actions go on simultaneously and continuously, as may be proved by shaking up freshly precipitated silver with either of the solutions for some time. The original greyish-black colour gives place to a nearly pure white, resembling a good iron-developed collodion image, and the powder becomes much finer. On one occasion we suspended a small "button" of pure silver in a flask of persulphate of iron, and in the course of a few days it had entirely disappeared, and a layer of brilliantly white metal covered the bottom of the flask.

There is another remarkable fact worth mentioning in connexion with the iron salts, namely, that, acting upon pure silver or on a collodion image, there is practically no deposition of basic ferric oxide, none, at any rate, beyond what might be expected to take place from the gradual passage of the iron to

a higher state of oxidation. But, directly the solution is applied to a gelatine negative, there is a copious deposition of the yellow powder, both on the film in the solution, and more slowly, in the film itself. This points almost undoubtedly to some special action of or on the gelatine, and may, in a measure, account for Liesegang's observation of the formation of a relief image on a gelatine plate by means of persulphate of ammonia.

As to the precise nature of the action upon a negative image, the solvent power of ammonium persulphate sufficiently accounts for that; but why it acts more forcibly on the high lights is not so clear. It seems to us reasonable enough, however, that, contemporaneously with the solution of the silver, a sort of physical redevelopment process goes on on the surface, which results in that portion of the image always remaining practically the same, until at least the action has continued long enough to dissolve the whole of the silver and leave no nucleus on which to redeposit it. Then we imagine there would be a slow and gradual deposition over the whole surface of the gelatine. This is, to all intents and purposes, Messrs. Lumière's explanation, and perfectly accounts for the selective reduction which, as Mr. John Sterry has pointed out, is actually a gradual undoing of development, the process proceeding upwards from the under side of the film.

Recent researches on the action of hydroxyl on silver salts would point to that as the undoubted reducing agent.

**Healthful Dark Rooms.**—In the old wet-plate days, when the fumes of collodion were so strong as to force themselves into notice, some effort was generally made to secure ventilation of a sort; but at the present time, when the chemical manipulations do not result in any evident deterioration of the atmosphere, the question of ventilation is rarely considered. But with the more prevalent use of gas as an illuminant it is highly advisable for those whose duties keep them for any considerable time in that room to see that the products of the combustion of gas are conveyed away as perfectly as possible. There are, as every one should know, distinct ill effects produced by the breathing of air contaminated with carbonic acid, which is one inevitable product. If carbon monoxide is also produced, as has been confidently asserted by some, the danger is very real—very insidious. The former mostly acts by reducing the proportion of oxygen, the latter is a distinct and deadly poison. We are, however, able, on the authority of Professor Grehant, who has been investigating the subjects of the result of combustion of coal gas under different conditions, to state that, under ordinary average conditions, carbon monoxide is not produced. Thus, with a common bat's-wing burner, the quantity found was so small that it could not be stated that it was not due to experimental error. But it is well to note that, when a gas flame strikes an object within a certain distance, the noxious gas is produced; hence no vessel should be heated by a naked gas flame in any room unless it is thoroughly well ventilated.

**Another New Incandescent Lamp.**—Still another electric lamp with luminous filament has been brought before the public, and from all accounts promises very highly. All users of this kind of lamp are too familiar with the fact that the higher the efficiency of an incandescent lamp the higher the illumination at the outset, and also the quicker the process of blackening the bulb and reduction of original intensity of light. It is asserted that in this new lamp of Herr Langhan's there is, however, a combination of high efficiency and freedom from blackening of bulb and of reduction of candle power. It has been run for from 600 to 800 hours, starting with an efficiency of about 3.1 watts per candle power, without any reduction of light-giving power, and the bulbs have not blackened. If all this be true, it is evident that through the advantages of increased light for a given consumption of electricity,

and there being less need for repeated change of lamps, considerable economy should result from the use of Herr Langhan's lamp. We read that the ordinary carbon filament of the glow lamp is in this case replaced by a filament of carbide of silicon and carbon, coated with silicon and carbon by the usual flashing process. The advent of such a lamp as this would be hailed as a boon by the users of the now common form of studio electric illuminant—the umbrella-shaped reflector faced with a row or rows of glow lamps, as it is obvious that the gradual diminution in illuminating capacity of the arrangement may, in the hands of those unfamiliar with the properties of incandescent lamps, easily occur without the knowledge of the user, and so perhaps the plate-makers be blamed for slowness of plates while the lamps only are to blame.

WITH regard to the Nernst lamp, which we have before described, and of which so much is expected, some details of the specifications of the patents have been published, and from them we learn that Herr Nernst finds that oxides of certain of the rare earths—magnesium, beryllium, thorium, and yttria—though of high resistance alone, may, when two of them are mixed, alone or with other substances, convey the electric current much more readily. The resistance of pure magnesian oxide was very high, but the addition of a small quantity of calcic chloride or of tungstic or boric acid so brought it down that a pressure of 100 volts served to produce incandescence when the filament was simply heated with the flame of a match. That the life of the filament might be prolonged as much as possible, the inventor found that metallic oxides only should be used, the particular form he preferred being as follows: zirconia, 95 per cent., and yttria, 5 per cent.; or thorina, 80 per cent., and yttria, 20 per cent.; or thorina, 94.7; zirconia, 3; yttria, 3; and ceria, 0.3 per cent. It seems very probable that we are really on the eve of a revolution in glow-lamp illumination.

**Photographing the Corona without an Eclipse.**—Signor A. Ricco, Director of the Catania Observatory, and others have been engaged for the last four years in attempting to obtain photographs of the solar corona without the aid of a solar eclipse. This observer in brief states that, though certain results have been obtained, there is no certainty that they are photographs of the corona. In the Belgian Society's *Journal* he gives a history of these various attempts illustrated by reproductions of the photographs obtained by various kinds of apparatus, and he shows that the only appearance produced is a sort of graduated halation, radiating equally in all directions from the solar disc. This is not to be wondered at. The only method that could possibly succeed would be one that would eliminate the whole of the light reflected and refracted by those particles always present more or less in the atmosphere between the region of the sun and the telescope. Seeing that these must consist more or less of radiations of all wavelengths, the problem is one which "passes the wit of man" to solve. It is possible that there may be heights of atmosphere beyond which the air is absolutely mote-free, and, if a telescope could be placed there and automatically worked in conjunction with a photographic arrangement, corona photographs might be obtained, but, so far, outside the works of Jules Verne, such regions have been and are likely to remain untenanted by either living beings or mammoth optical arrangements.

#### THE LATENT IMAGE AND THE NASCENT SILVER THEORY.

[Translated from the *Archiv für Wissenschaftliche Photographie*.]

We find, without exception, in text-books of photography, the view expressed that the substance produced by the direct action of light upon silver haloid is a silver sub-haloid. It is difficult to ascertain, in the present condition of photographic literature, who originated this theory, and upon what grounds it was based. We also find the same theory adopted in Eder's *Ausführliches Handbuch*, and its harmony with our experience is demonstrated. The theory that the substance of the latent image consists of metallic silver is likewise mentioned in the same work, but it is dismissed as unsatisfactory, without advancing any facts in

opposition. My object in submitting the following considerations is to show that the latter theory should be adopted as more probable.

1. We must bear in mind that, with the exception of sub-fluoride, the sub-haloids of silver are combinations whose existence is merely indicated, and their behaviour is such that, with equal probability, they may be said to consist of a mixture of normal haloid and metallic silver. Their indifference to nitric acid is the only reaction, which is opposed to the view that these substances, known as sub-haloids, contain an admixture of free silver, and it is not conclusive. It also appears, as might be proved by experiment, that the capacity of an exposed plate for development is almost destroyed by immersion in a bath of dilute nitric acid. This phenomenon is explicable if the substance of the latent image is metallic silver, but, if it is sub-bromide of silver, the impression formed by light should, on the contrary, withstand the action of nitric acid. It is evident that the well-known fact of the destruction of the latent image by the halogens is in consonance with both theories. The view that the image consists of metallic silver we shall briefly call the Nascent Silver Theory (*Silberkeimtheorie*), and, in addition to the above-mentioned proof in its favour, a series of observations, collected from the literature of the subject, may also be cited.

2. Eder observed, in 1880, that upon touching an unexposed plate, immersed in developer, with a silver wire, reduction took place where there was contact. In this instance it is certain that metallic silver is the cause of extensive reduction of unexposed silver halogen contained in the film, and that the reduction takes place continuously, adjacent to the nascent silver which is first formed.

3. If the sub-haloid theory is carried to its logical conclusions, the activity of nascent silver must also be admitted, for, as soon as the sub-haloid, supposed to have been formed by light action, has been reduced to silver by the developer, any further strengthening of the image must be brought about by the formation of nascent silver. This strengthening of the image when the nascent silver is formed, and which takes place proportional to its quality, is a further proof of the nascent silver theory.

4. The experiments of Abney also testify very conclusively in the same manner. A negative, if coated with unexposed emulsion, may be intensified by development. Reduction of the silver bromide begins in the vicinity of the silver particles of the original negative. This agrees with the nascent silver theory, and in this instance there cannot be any question of the formation of a sub-haloid. The same explanation also accounts for another similar experiment made by Abney, in which an image is developed in an unexposed film coated upon an exposed but undeveloped plate. The image develops simultaneously in the exposed and unexposed films, but it should be noted that the image is stronger in the upper than the lower film, which gives further support to the nascent silver theory. It shows, in the first place, that the exposed film is not specially predisposed to development; and, secondly, that reduction is proportional to the strength of the developer, and spreads in all directions from the nascent silver at the contact of both films. In the upper film, where the fresh developer is active, the image is more vigorous than in the lower film, which is not permeated by the developer until some strength has been lost. An explanation of these phenomena has recently been offered by recourse to a quite incomprehensible theory of electro-magnetic light, Faradaic induction, dielectrics, &c., but the results of Abney's experiments might be predicted with certainty in every detail by the nascent silver theory, without resorting to any such scientific monstrosities. A beautiful confirmation is also presented in a counter experiment made by Eder, at Bredig's suggestion. If an exposed, but undeveloped plate, is coated with a film of gelatine free from silver haloid, and then with a film of unexposed emulsion, the image develops only in the lowest film, where the exposure was made. It is evident that the interposed film of gelatine deprives the top film of contact with the nascent silver.

5. An opinion has recently been expressed by Guébbardt that the sensitiveness of rapid plates is due to presence, before exposure, of a slight amount of fog. This would be nascent silver. What we have said seems to confirm this. The ripening process, which renders the emulsion sensitive, would, therefore, seem to be productive of nascent silver through the slightly reducing power of the gelatine. This at the same time elucidates the mechanism of chemical sensitisation, so far as concerns gelatine at least. It should therefore be expected, and experience confirms the fact, that over-ripening produces sufficient nascent silver to render the plate developable without exposure. The plate fogs, and the riper, or more sensitive, the emulsion, the more apparent does the fog become.

The cleaner a plate must work, as for photo-mechanical purposes or transparencies, the less must be the amount of nascent silver due to

chemical sensitisation instead of exposure. Collodion has no reducing power and is not a chemical sensitiser. For this reason collodion and the Daguerreotype plate (wholly unsensitised) fulfil this condition best. Phenomena of ripening are accordingly unknown in the case of collodion emulsion. Ripening has often been described as a modification of the silver bromide, because there is simultaneous increase in the size of the grain. But we learn from observation that difference in the grain is first seen in the developed negative, and almost, if not quite, absent from the undeveloped plate. Silver bromide consequently appears to be unaffected by the ripening process, in so far as it remains silver bromide. Professor Ostwald has informed me by letter that change, by modification of the silver bromide, would appear to be excluded, as its occurrence, being spontaneous, could only produce a more stable modification, less liable to decomposition, which would mean the reverse of ripening. As the presence of gelatine is necessary to the ripening process, its chemical action (formation of nascent silver) must be regarded as the cause of ripening.

6. A phenomenon, which has recently been brought to light again, and which at first sight appears very extraordinary, is the possibility of developing a plate, which has been exposed and then fixed. This is of easy explanation by the nascent silver theory, and might be expected to take place. When an exposed plate is fixed, the nascent silver formed by exposure remains unaffected by the fixing salt, and in the process of physical development must possess the same attraction for silver in the presence of a solution which precipitates silver as an unfixed plate under ordinary development. When considered in this manner, the difference between chemical and physical development becomes one of mere superficial character. In both cases the reducing constituent of the developer produces finely divided metallic silver. This takes place either from the silver salt contained in the film, or added to the developing solution, and the nascent silver, by its attraction,\* forms most deposit where its presence is most abundant. Kogelmann's† discovery has been reinvestigated recently by Neuhaus,‡ who states that physically developed negatives of this kind have a finer and more evenly distributed grain as compared with the coarse negatives obtained by ordinary chemical development. This is in accordance with experience, as we find that negatives by the wet-collodion process, which are also physically developed, are much finer in the grain than those obtained with gelatino-bromide plates. This may perhaps be explained by deposition upon the nascent silver image of a fine even precipitate of silver particles from the solution in physical development, whilst, in the process of chemical development of a gelatine plate, the nascent silver image reduces in their entirety the coarser particles of silver bromide by which it is surrounded. The long series of ingenious experiments instituted by Kogelmann† have also demonstrated that the latent image may consist of metallic silver. Those, however, which made Kogelmann incline to other conclusions are partly inconclusive in their proof, and partly contradicted by Abney's experiments, which have been confirmed by other authors.

7. It is firmly established that the development of the latent image depends upon the presence of nascent silver, and it is therefore preferable to conclude that the nascent silver is formed by the direct action of light, rather than the developer, as required by the sub-haloid theory. The solubility of the substance of the latent image in nitric acid, to which the sub-haloid is indifferent, according to Guntz, is entirely in favour of light being the direct cause of the nascent silver, and this conception is, doubtless, that which most readily agrees with experience.

DR. RICH. ABEGB,

*Institute for Physical Chemistry, Göttingen.*

#### FOREIGN NEWS AND NOTES.

**The Paper Ring.**—We mentioned a short time ago that the Chemische Fabrik vormals E. Schering had undertaken the manufacture of photographic paper, in conjunction with Felix Schüller, jun., at Burg Gretesch, near Lüstringen, as they were unwilling to comply with the pretensions of the monopolists. They succeeded in producing a suitable paper, but, as the "ring" had made arrangements with the manufacturers who coat the baryta that they should use none but "ring" paper, it was necessary to overcome the difficulties of this process also. The Chemische Fabrik had just placed

\* The nature of this attraction need not be discussed here, but, from various observations, it may be taken as not exclusively associated with silver, as, for instance, the intensification of platinotypes by a fine deposit of platinum, the silver intensification process, the deposition of precipitates upon rough surfaces, &c.

† Die Isolirung der Substanz des latenten Photographischen Bildes. Gratz: 1894.

‡ Photographische Rundschau, 1893, vol. xii. p. 257.

upon the market a celloidine paper of their own manufacture throughout, and the *Deutsche Photographen Zeitung* speaks in very high terms of praise of the quality. We trust the Chemische Fabrik will see its way clear to supply other manufacturers with paper, and thus bring the "ring" to its knees.

**The Photographs of Bismarck.**—The *Photographische Chronik* mentions that the photographers, Wilcke & Puëster, of Hamburg, who secured photographs of the late Prince Bismarck after death, have been ordered to deliver up the negatives to the family to be destroyed. They have also been forbidden to publish copies under penalty of six months' imprisonment for each offence.

**Xylolith.**—An Austrian firm has brought out a material under this name, which should be of great value for studio floors if it is reasonable in price and possesses the qualities claimed for it. It is formed by mixing sawdust with calcined magnesias and mixing it to a paste with a solution of magnesium chloride. In this state it may be used for coating floors, or it may be made into sheets or tiles. It is very tough and hard, does not burn, and carbonises only at very high temperatures. It is a bad conductor of heat, withstands moisture and dilute acids, and its specific gravity is 1.5.

**Cleaning Mirrors.**—The *Photographische Chronik* gives the following directions in answer to a correspondent. The mirror should be placed upon a thick metal plate and slowly warmed, to drive off any moisture on the silver film. Should any moisture be present, the slightest touch would injure the mirror. The wash-leather used for polishing should also be warmed for some time before use, and should be perfectly clean. A trace of English rouge, such as used by goldsmiths, should be rubbed on the warm leather, and the mirror may then be repolished with the leather by gentle rubbing in a circular direction.

**Backing Plates.**—The *Photographische Chronik* recommends the following, as a good backing for dry plates, to those who object to the stickiness and stain of most compounds used for the purpose. Take 15 grammes of clean Castilian soap scraped to a powder, and add to it 800 c. c. of strong alcohol; well stir it, and let it stand eight or ten days; filter through paper and dissolve 3 grammes of erythrosine and 3 grammes of aurine in the solution. The liquid should be applied to the back of the plate with a brush or sponge, and it dries instantly. It may be removed with a wad of wet blotting-paper.

**Coloured Screens.**—A simple method by which these can be made is given in the *Bulletin de la Société Française*. Take an iron ring that will fit the hood of the lens, clean it perfectly, and place it on the surface of some mercury in a saucer. The ring will float upon the mercury. Stain some suitable collodion, and pour it into the ring. Cover with a sheet of paper, to preserve the film from dust until dry.

**Glycin.**—Dr. Eder gives the following directions, in the *Photographische Correspondenz*, for the preparation of a thick concentrated solution that will keep well. Dissolve 25 grammes of sulphite of soda in 40 c. c. of water in a dish by heat, add 10 grammes of glycin, heat to boiling point, and add at intervals 50 grammes of carbonate of potash. A somewhat thick solution is formed with effervescence and liberation of carbonic acid. When cold, pour into a glass measure, and, if necessary, add sufficient water to make up to 75 c. c.; store in stoppered bottle. For use, dilute with 12 parts of water. For stand development, add 50 parts of water. A ten per cent. solution of potassium bromide is a useful restrainer. Caustic potash may be used as an accelerator, but is seldom necessary.

#### OZOTYPE.

This process of printing, due to Mr. Thomas Manly, is described by the inventor in the Patent specification. Mr. Manly says:—

I coat in any convenient way paper, or other suitable material, with an aqueous solution (which I shall hereafter refer to as the sensitising solution) containing the following ingredients, namely, the bichromate salts, or chromic acid, or other similar light-sensitive compounds of chromium, manganous sulphate, or manganous chloride, or other manganous salts, and a preservative, such as boric acid and aluminium sulphate or alum, mixed together in suitable proportions.

In place of the above-mentioned salts of manganese, the cupric, cobaltous, and nickel salts, and other metallic salts capable of giving oxides on exposure to light in presence of the light-sensitive compounds of chromium may be used. After the paper or other material thus prepared and rendered sensitive to light has been dried, it is exposed to light under a negative or other screen, producing a brown positive image in manganic oxide or manganese dioxide. The printed paper, or other material, is cleared of all the unchanged salts by washing in water, and will be hereinafter referred to as the print.

In order to produce a picture or image in pigment, I adopt either of the following methods:—

1. I take paper coated with pigmented gelatine commonly called carbon tissue, and proceed as follows:—

I dip the carbon tissue for about one minute and a half, or thereabout, in a weak solution of acetic acid and hydroquinone, or of acetic acid, hydroquinone, and ferrous sulphate, which I will hereafter refer to as the acetic solution. At the expiration of one and a half minute, or thereabout, I take the washed print and, having given it a coating of a two per cent. solution of gelatine, I plunge it under the surface of the acetic solution, and bring it in contact with the surface of the carbon tissue. I then draw the print (with the carbon tissue clinging thereto) out of the solution and squeeze them together on a flat surface. After surface-drying, they are hung up to dry. When quite dry, I place the print, with its adherent carbon tissue, in cold water for about half an hour. It is then ready for development, which is performed by placing it in water at a temperature of 43° C., or thereabout, removing the backing of the carbon tissue, and washing away those parts not rendered insoluble by the action of the manganic oxide, thus giving an image in pigmented gelatine.

2. Or I coat the washed and dried print with a hot solution of pigmented or coloured gelatine, using preferably such a solution as is used in the preparation of carbon tissue, and, as soon as the gelatine coating is dry, I dip the print thus treated for about one minute in the acetic solution above referred to. I now hang the pigmented print up to dry, and, when thoroughly dry, I develop the image by dissolving in water, at a temperature of 43° C., or thereabout, those portions of the gelatine coating not rendered insoluble by the action of the manganic oxide.

In order to produce an image in aniline colours, I dip the washed print in the following solution:—

Aniline hydrochloride .....	about 20 grammes,
Sulphuric acid .....	" 2 c. c.
Water .....	" 300 "

which converts the image into a green colour. If the image is treated with a weak solution of ammonia, a purple image is produced: and, if chloride or bromide of copper be added to the above-described aniline solution, a dark blue image is the result.

Other substances, such as various phenol derivatives and amido-phenols giving colour on oxidation, will produce coloured images.

In preparing the sensitising solution mentioned above, I use by preference the following formula, coating the material twice with same.

The under-mentioned solutions are first prepared separately:—

A. A saturated aqueous solution of potassium bichromate, to which has been added as much boric acid as it will dissolve at a temperature of 16° C., or thereabout.

B. Manganous sulphate .....	25 parts to 100 parts distilled water.
C. Manganous chloride .....	25 " 100 "
D. Aluminium sulphate .....	25 " 100 "
E. Dextrine or gum arabic .....	1 part to 2 " "

To make a solution for sensitising paper or other material, the above-mentioned solutions are mixed in the following proportions:—

A. ....	10 parts.
B. ....	4 "
C. ....	2 "
D. ....	1 part.
E. ....	1 "

The following is a formula for the acetic solution already referred to; but so much depends upon the character of the negative and the constitution of commercial carbon tissue, that the ingredients may have to be modified in quantity to produce the best results:—

Magnesium sulphate .....	10 grammes.
Glacial acetic acid .....	8 c. c.
Hydroquinone .....	2 grammes.
Ferrous sulphate .....	25 or 1/2 gramme.
Water .....	1000 c. c., or 1 litre.

Other reducing agents may be used in place of the hydroquinone, such as pyrogallol, in some cases.

In the case of prints to be subsequently treated with pigmented gelatine in the form of carbon tissue, I claim the following advantages over other similar known processes, namely:—

1. The image is visible during the progress of printing, and when washed is permanent.

2. The picture being produced on the material, where it will permanently remain, does not become reversed in the operation, as in the present method of carbon printing.

3. No precaution need be taken to guard against the edges of the picture washing up during development.

4. As it is necessary that the chromic salts should be thoroughly washed out of the print before development, the hands of the operator do not come in contact with any deleterious solution.

5. No insoluble gelatine is necessary on the material to be sensitised. In case of prints treated with aniline and other similar salts, I claim the advantage of simplicity of production and novelty.

Mr. Manly's claims are:—

1. A solution containing one or more of the light-sensitive compounds of chromium in conjunction with one or more of the manganous salts for the preparation of a light-sensitive surface for the production of photographic images.

2. A suitable material, such as paper, rendered sensitive to light by the application of a solution containing one or more of the light-sensitive compounds of chromium, in conjunction with one or more of the manganous salts, for the production of photographic images.

3. The production of photographic images in pigmented or coloured gelatine, by exposing the sensitive material described in Claim 2 under a negative or other screen to obtain a print, fixing such print by washing it in water to remove the unchanged salts, drying the same and bringing it in contact with pigmented gelatine in a solution containing acetic acid and a reducing agent such as hydroquinone, drying again, and developing the image by dissolving in hot water those portions of the pigmented gelatine which have not been rendered insoluble by the action of the oxide constituting the image.

4. The production of photographic images in pigmented or coloured gelatine by exposing the sensitive material described in Claim 2 under a negative or other screen to obtain a print, fixing such print by washing it in water to remove the unchanged salts, drying the same, coating it with a hot solution of pigmented gelatine, allowing the same to dry, dipping the print thus treated in a solution containing acetic acid and a reducing agent, such as hydroquinone, drying again, and developing the image by dissolving in hot water those portions of the pigmented gelatine which have not been rendered insoluble by the action of the oxide constituting the image.

5. The use of a sensitised paper or other material, such as described in Claim 2, giving an image in metallic oxide on exposure to light for the production of coloured images by treatment with aniline and other salts, capable of giving colour on oxidation.

6. The production of photographic images in oxides by the exposure of a surface rendered sensitive to light by the application of a solution containing one or more of the light-sensitive compounds of chromium, in conjunction with a metallic salt capable of being converted into an oxide by the action of light on the sensitive chromium compounds.

#### IMPROVEMENTS IN THE COOKE LENS.

MR. H. DENNIS TAYLOR'S description of his patented improvements in the Cooke lens is as follows:—

It is often of the greatest importance to photographers to have the power of altering at will the focal lengths of their lenses. In the case of rectilinear lenses, each half of the lens may itself be used as a lens of about double the focal length of the complete combination. But there are lenses of other types, especially that known as the "Cooke" lens, in its various series, whose constituent lenses cannot be separately employed for photographic purposes as lenses differing in focal length sufficiently from that of the complete combination, and this invention is for the purpose of supplementing this deficiency in a sufficiently simple and effective manner. In the case of all the Cooke lenses described or comprised in the Patent Specifications No. 22,607 of 1893 and No. 15,107 of 1895, the back lenses of the combinations are elementary or simple, and the essence of this my invention is the device of making these simple back lenses interchangeable with one or more supplementary simple back lenses made of glasses differing in dispersive power, and varying in focal length substantially as their dispersive powers, thereby keeping the state of achromatic correction practically constant, while permitting of very considerable alterations in the focal lengths of the whole combination.

These interchangeable back lenses may be either mounted each into a separate cell to screw into the back of the lens mount, in place of the normal back lens, or may be mounted in a sort of wheel, sector, or swivel, all equally distant from the centre of such wheel, &c., each lens in turn being brought into correct position behind the permanent parts of the Cooke lens, by means of rack or lever and a light spring detent. Or they may be mounted two or three together in a straight slide working to and fro. Various other methods of mounting or interchanging these lenses may be devised.

The changed equivalent focal length may be expressed by the following formula, where—

$F$  = the equivalent focal length of the whole combination with its normal back lens.

$u$  = the distance from the back lens of a point on the optic axis to which or from which the axial rays are converging or diverging before

entering the back lens;  $u$  is positive if the rays are divergent, and negative if they are convergent.

$b$  is the focal length of the normal back lens.

$c$  is the focal length of the supplementary back lens.

$x$  is the required focal length as modified by the use of the supplementary lens (whose focal length is  $c$ ).

Then—

$$X = F \frac{u - b}{u - c} \cdot \frac{c}{b}$$

If the rays entering back lens are parallel, and therefore  $u = \infty$ , then  $X$  is simply  $F \frac{c}{b}$ . The rays are diverging before entering the back

lens of the Cooke lens, series 111<sup>a</sup> (described in Patent Specification No. 22,607<sup>93</sup>, pages 10 and 11), and the back lens thereof is made of a borosilicate crown, having the very low dispersive power of  $\frac{1}{50.5}$  for rays

D to G. This back lens may be changed for one of extra dense flint glass, which may be of double the focal length of the normal back lens, since its dispersive power is double that of the borosilicate crown, or  $\frac{1}{25}$  for the same rays D to G. In this case, doubling the focal length

of the back lens more than doubles the focal length of the whole combination, as may be seen below. I will now give a list of schedule indicating the curves of several interchangeable back lenses for use in conjunction with various Cooke lenses. All the radii of curvature are expressed in terms of the equivalent focal length of the normal combination or Cooke lens to which they are applied. Therefore, to obtain the actual radii of curvature of such interchangeable lenses, the figures given for radii must be multiplied by the equivalent focal length of the normal combination for which they are intended. All refractive indices are for the D ray, and all dispersive powers for the rays D to G.

#### COOKE LENS, SERIES 111<sup>a</sup>.

This lens is described in Patent Specification, No. 22,607 of 1893, pp. 10 and 11, and fig. 8 of drawings. Radii of normal back lens = +1.265 and 5843. The glass is borosilicate crown, having a refractive index of 1.5101 and a dispersive power =  $\frac{1}{50.5}$ .

1. One interchangeable lens may be made of a light flint glass, having a refractive index = 1.5482 and dispersive power =  $\frac{1}{35.2}$ ; curves + 1.23 and + 1.23 (equi-convex). This lens, in place of the normal back lens, will increase the normal focal length by about 1.6 times.

2. Another interchangeable lens may be made of extra-dense flint glass, having a refractive index of 1.6527 and a dispersive power of  $\frac{1}{2}$ ; curves + 1.77 and + 2.47. This lens, replacing normal back lens, will increase the normal focal length by about 2.6 times.

#### COOKE LENS, SERIES 111<sup>b</sup>.

This lens is described in Patent Specification No. 15,107 of 1895, p. 12 and fig. 8 of drawings. Radii of normal back lens = +3.623 and +770, and the glass is dense barium crown. Refractive index = 1.6114; dispersive power =  $\frac{1}{44}$ .

An interchangeable back lens may be made of extra dense flint of refractive index = 1.6527 and dispersive power =  $\frac{1}{25}$  curves + 2.35 and + 2.35 (equi-convex).

This lens, replacing the normal back lens, will increase normal focal length by about 1.6 times.

#### COOKE LENS, SERIES V.

This lens is described in Patent Specification 15,107 of 1895 on p. 14 and fig. 10 of drawings.

Radii of normal back lens = +10.12 and +.6975, the glass being dense barium crown having refractive index = 1.6114 dispersive power =  $\frac{1}{44}$ .

An interchangeable back lens may be made of extra dense flint glass having refractive index = 1.6527 and dispersive power =  $\frac{1}{25}$  curves + 8.06 and + 2.04.

This lens, replacing the normal back lens, will increase the normal focal length by about 1.5 times.

The above are the interchangeable lenses likely to be the most useful. Of course, other interchangeable lenses may be worked out which will give more moderate changes of focal lengths should they be desired. It would scarcely answer, however, to resort to a flint glass at all denser than that above specified of which to make an interchangeable lens for a still greater elongation of focal length.

The claim is for the application to photographic lenses of the character herein described, possessing simple back lenses, of interchangeable simple back lenses, made of various glasses and varying in their focal

lengths approximately as their dispersive powers for the spectrum interval, D to G, whereby considerable variations in the equivalent focal lengths of the whole combinations may be obtained, such interchangeable lenses being either mounted in separate cells for screwing or otherwise fitting into or on to the back of the compound-lens mount, or else mounted on a slide, wheel, sector, or other mechanism whereby they may be quickly interchanged.

#### PALLADIUM TONING.

Before the Richmond Camera Club, on March 13, Mr. G. Ardaseer read a paper on palladium toning. After prefacing his remarks with a short account of the metal and the mode in which it was obtained, he said that there did not seem to be any reason why palladium and iridium, in common with the nearly related metal, platinum, should not be used for toning silver prints. He had experimented with iridium, but without success. As regards palladium, however, he had been able to produce results which were decidedly encouraging, and he passed round some small prints on matt-surface paper, the tones of which he thought would be considered pleasing. They varied from a warm brown to a sepia, but as to their permanency, he could as yet give no opinion. He thought, however, that time spent in such experiments as this was not wasted. The knowledge gained from some small experiment had frequently led to important results; for example, the present platinotype process owed its origin to a test-tube experiment.

Mr. Ardaseer said that the salt of palladium to be used in toning was the chloride, and that the best form in which to obtain it was in solution. An ounce bottle containing ten grains of chloride could be obtained from Messrs. Hopkin & Williams, Cross-street, Hatton Garden, for three shillings, and, although at first sight it seemed somewhat expensive, it was not really so, as a little went a long way.

The first formula he would recommend was as follows:—

Palladium chloride solution .....	30 min.
Citric acid .....	20 gr.
Sodium chloride (common salt) .....	30 "
Water .....	10 ounces.

The prints should first be put into a bath of salt and water; so as to convert the free nitrate of silver into chloride of silver, and, after well washing, into the toning bath, where they should be left till they were a warm purple on the surface. They should then be put in a bath of washing soda (half ounce to twenty ounces of water) to neutralise the acid and prevent sulphur toning, and then into the hypo bath, which should be half strength (1 in 10). The prints changed considerably in appearance in the fixing bath, but, when washed and dried, they assume the warm brown or sepia colour referred to above.

There was another toning bath without salt, viz.:—

Palladium chloride solution .....	15 min.
Citric acid.....	10 gr.
Water .....	10 ounces.

This gives warmer tones, but the prints undergo considerable reduction in it.

Mr. Ardaseer then toned some prints he had brought with him, leaving some in the toning bath longer than others, and he promised to bring them to the next meeting, so that the members might see the results when dry.

#### ON HYDROGEN PEROXIDE AS THE ACTIVE AGENT IN PRODUCING PICTURES ON A PHOTOGRAPHIC PLATE IN THE DARK.\*

In former papers it has been shown that the active bodies, both metallic and organic, are able to act on a photographic plate even when thin layers of many different substances are interposed; for instance, if a thin sheet of gelatine be laid on a polished zinc plate, it only very slightly modifies either the sharpness of the picture or the time required for its production. If the gelatine plate be thicker, the action will still pass through, but the picture will be more indistinct and the time necessary for its production longer. If a two per cent. solution of hydrogen peroxide be poured into one of the small glass dishes, and a sheet of gelatine 0.0015 inch thick be placed over it  $\frac{1}{2}$  inch above the liquid, a picture will be obtained in fifteen minutes. If the sheet of gelatine be 0.008 inch thick, then the exposure must be for one hour; and, if the gelatine be 0.01 inch thick, an exposure of three hours is necessary. If a sheet of celluloid be substituted for the gelatine, and it be 0.005 inch thick, the action still passes through, but more slowly than through the gelatine, and the plate now requires one hour exposure to give a good picture. With a plate of celluloid of double the above thickness, the exposure must be four times as long; and, if the thickness be 0.033 inch, the time of exposure has to be thirty hours. These determinations show well what happens in these cases, but are only good approximations, not standard results. In addition to gelatine and celluloid, gutta serena tissue, india-rubber tracing paper, collodion, albumen, goldbeaters' skin, parchment, &c., also allow the action to take place through them, and the obvious question which presents itself is, If hydrogen peroxide be the body

which gives rise to the action, how does it pass through these different bodies? Take the definite case of zinc, if a plate of this metal be rubbed with coarse sand paper and placed in contact with a photographic plate, a clear and sharp picture of the scratches is obtained, and it might have been expected that, when the action took place through even a very thin sheet of gelatine, the picture of the scratches would have no longer been visible, or at least only indistinctly so, but experiment shows this is not the case. How, then, does the peroxide permeate the gelatine? Not by the ordinary process of diffusion, for hydrogen cannot diffuse through it, so that it must be by a process of dissolving, or very feebly combining with the medium or with a constituent of it, and thus travelling through escape on the other side. That the action is of this nature seems rendered probable by the following experiments, which show, at least to some extent, what takes place:—

A two per cent. solution of hydrogen peroxide was placed in a dish with a sheet of the thinnest gelatine about one hundredth of an inch thick; above it and on the gelatine a photographic plate was placed, and allowed to remain there for twenty minutes. No picture was formed. Immediately on removing this first plate from gelatine a second one was put in its place, and allowed to remain there also for twenty minutes. This plate gave a faint picture, the third one gave a darker picture, and the fourth one was still darker; but the fifth, sixth, and seventh plates were, as far as could be judged by the eye, of the same degree of darkness. Thus the amount of peroxide given off on the upper surface of gelatine went on increasing for one hour and twenty minutes, and then the action became uniform. The same kind of action occurs if zinc be used in place of peroxide solution. If a thin sheet of gelatine be laid on a piece of zinc and allowed to remain there for a week, then, on placing above it a sensitive plate, a picture will be produced in about one-third to one-fourth the time which would have been necessary if the previous exposure to the zinc had not taken place. Celluloid was found to act exactly in the same way as the gelatine. The plate, after the first half-hour's exposure, gave no pictures, but a faint one after the second half-hour; and it was not till after the fourth half-hour that the action became constant. A thicker specimen, 0.011 inch thick, was also examined after intervals of two hours; it acted in the same way as the other specimens, but required ten and a half hours before the action became uniform. If drying oil or copal varnish be used in place of the peroxide of hydrogen solution, analogous results are obtained. This action explains how pictures can be obtained from invisible originals. If, for instance, a piece of white cardboard or paper is placed behind a copper stencil and is exposed to the vapour from peroxide of hydrogen solution, drying oil or copal varnish, &c., the exposed part of the paper becomes active, although not visibly affected, and, on placing it on a sensitive plate, a picture of these parts is produced. Zinc acts in the same way, but only slowly. A zinc ornament, laid on a piece of Bristol board for eight months, charged the board only so far as to enable it to give a faint picture.

Gelatine can be substituted for the paper in these experiments, and can be charged and made to convey a clear picture to a sensitive plate. It is, then, evident that the action arising from zinc and other active bodies can, by an intermediate and inactive substance, be carried away and allowed to expend itself at another time and at another place.

With regard to the transmission of the action through gelatine, the water which it contains is probably the body which enables the peroxide to pass through. It can also be shown that it aids the transmission of the action through other inactive bodies; for instance, if Bristol board in its ordinary condition be placed on a polished piece of zinc, the action of the zinc only slowly passes through it, but if the board be damp the transmission takes place much more rapidly. The following comparative experiments illustrate this: Two similar pieces of Bristol board were taken; one was dried and then placed between a piece of perforated zinc and a sensitive plate and put under a bell jar with calcium chloride; the other piece of Bristol board was suspended over water until it was thoroughly damp and then placed between perforated zinc and a sensitive plate under a bell jar with a little water present. Both experiments were continued for twelve days, when it was found that with the dry board there was no picture produced, but with the damp one there was a good and dark one. If copal varnish be used in place of zinc, similar results are obtained, and, if parchment be substituted for Bristol board, the results are the same.

These experiments are, however, not conclusive, for it has been shown that with additional amount of water some of it finds its way to the zinc, and there induces the formation of more peroxide, which may account for the darker pictures. Even with the terpenes the additional amount of water may induce the additional formation of peroxide. This objection can, however, be obviated by cutting off the moisture in the damp medium from the active substance, or by using the aqueous solution of the peroxide as the origin of the action. In order to stop the aqueous vapour from either passing from the damp Bristol board or to it from the peroxide solution, a piece of tracing paper is interposed which allows the action to pass through it, but not any appreciable amount of aqueous vapour. On placing a sheet of tracing paper over a glass dish containing the peroxide solution and above it dry Bristol board with a photographic plate, in one and a half hours just an indication of a picture was produced, but when under the same conditions Bristol board, which had

been over water for nineteen hours was used, then a dark picture was formed. Again, similar experiments were made using a not highly glazed paper in place of the Bristol board, and the results were the same.

In place of tracing paper, celluloid was used and the dry Bristol board gave, under similar conditions, no picture, but the damp one a very distinct picture. In order to avoid having so much water present, plaster of Paris set by a little of the peroxide solution was used in place of the aqueous solution, and exactly similar results were obtained, so there is no doubt that hydrogen peroxide can readily pass through a porous body by the aid of water.

Alcohol acts in the same way as water, for, when plaster of Paris wetted with peroxide solution was poured into a couple of similar dishes and allowed to set, and over one a piece of dry, and over the other a piece of Bristol board moistened with alcohol were placed, and sensitive plates above them, after fifty minutes only a very faint picture was formed above the dry board, but a dark one over the wetted board.

Celluloid is, however, nearly as transparent to these actions as gelatine, and water in this case cannot be the transmitting medium, so that the question is whether there be any constituent of the celluloid which may act in a similar way to that of water in the gelatine. From the following experiments it seems that camphor can do so:—

Camphor itself, like water, is a perfectly non-active body. To obtain a thin non-porous layer of this body is difficult, but it is easy to prove that the emanations from hydrogen peroxide solutions, from zinc, copal, or other active bodies, are readily absorbed by it and readily pass through it. For instance, if a piece of camphor be placed about a quarter of an inch above a two per cent. solution of hydrogen peroxide for seventeen hours, and be then removed and placed on a sensitive plate for fifteen minutes, it gives a dark picture, and when a similar experiment is made, using drying oil in place of the peroxide solution, and the camphor be exposed to its action for three days and then brought in contact with the sensitive plate for one day, a dark picture is produced. This action can, however, be easily carried still further and proved to pass through even a thick layer of camphor. A piece 0.137 inch thick was placed about one-eighth of an inch above a two per cent. solution of peroxide in a dish for sixty-six hours, and a sensitive plate placed on the top of it; on treating this photographic plate with the developing solution, it was found that a considerable amount of action had occurred. Thus the camphor, which is a principal constituent of celluloid, may enable hydrogen peroxide to pass through it.

That gutta percha and pure indiarubber should allow the action to pass through them is remarkable. The substance known as gutta-percha tissue has a thickness of about 0.003 inch, and allows the action to pass readily through it; in fact, if even two thicknesses of this tissue be placed over the two per cent. solution of the peroxide for seventeen hours, a dark picture is obtained. If the tissue be laid on a polished piece of perforated zinc, and a sensitive plate above it, after remaining there for a fortnight a fairly good picture is obtained. If drying oil be used, the action will pass through the gutta percha in three days. With regard to this transmission of the action, although the chemical constitution of gutta percha is not well established, it is said to be a body related to camphor (Bernthsen, *Organic Chemistry*, p. 509), and hence the action passes through it as it does through celluloid, and this is borne out by the fact that, if a piece of gutta percha be placed for eighteen hours over the two per cent. peroxide solution, and then placed for twenty minutes on a sensitive plate, it evidently has become active, for it then gives a good picture.

The above remarks apply also to indiarubber. The thinnest sheet that has been experimented with is 0.017 inch thick; this allowed the action to pass through it, but was too thick to give a picture; but, like the gutta percha, if placed over the peroxide solution, it became active, and produced considerable action on a photographic plate.

With regard to other substances which allow the action to take place through them, the most interesting are true goldbeaters' skin and albumen. If Bristol board or paper be carefully painted on one side with white of egg and allowed to dry in the air, it forms a medium through which the peroxide can pass. Collodion also allows the action readily to pass through it. In all these cases the tetra paper may be used to confirm the results obtained.

Then with regard to bodies which do not allow the action to pass through them. Paraffin is one of them. If paper be painted with melted paraffin, and it be placed over a solution of the peroxide, no action passes through, neither is it able to absorb the peroxide like camphor, and indiarubber, and gutta percha. A piece of paraffin placed over the peroxide solution for twenty hours, and then tested by placing it on a sensitive plate, produced no action.

Gum arabic is a body which sometimes is very opaque; but this is simply a question of hydration, and is confirmatory of what has been said before with regard to the action of water. Some unglazed paper was painted on one side with two coats of good gum arabic, and some of it was dried at 55° for some days, and another portion of it was air-dried only for some hours, and both were put over drying oil for three days. The dried paper gave only a very faint picture, but the more moist one a very dark picture.

When experimenting, some time ago, on the general nature of these reactions, polished zinc was placed below some inactive liquids to test

whether any action took place through them. The small glass dishes were used, and a disc of bright zinc laid inside, and the liquid to be tested poured upon it; then the photographic plate was placed on the top of the dish. After remaining there for three or four days, the plate was generally found acted on as if the zinc had been able to exert its influence upon it. Lately these experiments have been repeated and extended, and, as indicating the extreme delicacy of the reaction with the photographic plates, are of interest. The form of experiment was the same as described above, and the liquids used were alcohol, ether, ethyl-acetate, chloroform, benzene, petroleum spirit. All these liquids were purified, so that, when placed in the dish with the sensitive plate above them, no action, after a week's exposure, took place. However, when a zinc disc was introduced below the inactive liquids, the photographic plate was generally acted on; but with the benzene and petroleum spirit sometimes no action occurred. These rather singular results were next tested in another way. Portions of these inactive liquids were put into stoppered bottles with polished strips of zinc foil, and allowed to remain there for a week, and it was then found that the liquid had become active, for on testing it, by putting it into a dish with a photographic plate above it, a dark picture was formed, so that the action of the zinc was to make the whole of the liquid active. Magnesium, cadmium, aluminium, fusible metal, and bismuth all produced effects similar to those obtained with the zinc, but nickel, lead, tin, &c., produced no such effects. Further, it was proved that a very small amount of peroxide rendered alcohol, for instance, very active; 0.1 c. c. of a two per cent. solution of the peroxide added to 10 c. c. of alcohol gave it the power of acting on a sensitive plate  $\frac{1}{2}$  inch above the surface, so as to produce, in a few hours, a dark picture. The still more careful purification of these liquids, and especially the exclusion of moisture, was undertaken, and in every case it was found, when all moisture was excluded, that the zinc had no longer the power, when below a liquid, of acting on a photographic plate. Specimens of alcohol, ether, and chloroform were prepared, and these, when placed in a dish with zinc at the bottom of it (standing over sulphuric acid), allowed no action to pass through them, and when treated for a week or more with bright zinc in a bottle, still retained their perfect inactivity. To a sample of the alcohol which, in a dish with zinc, allowed no action on the sensitive plate above to occur, a trace of water was added—as much as adhered to the end of a thin glass rod—and now, with the same length of exposure, a dark picture was formed. From these experiments, as well as those previously mentioned, it appears that this action on the photographic plate is one of extreme delicacy.

The action of water alone on zinc is interesting, and appears to confirm the view that hydrogen peroxide is the active agent in all these reactions. It has already been shown that, although bright zinc is active, dull zinc is inactive. However, if a piece of bright zinc be placed in water, and remains there for twenty-four hours or so, it, of course, oxidises, white spots or lines appear, and, in fact, in time the whole surface would become covered with oxide. Now, the oxide thus formed is strongly active. Take the plate out of the water, let it dry, place it in contact with a photographic plate, and a strong picture of the spots of oxide is obtained. No doubt peroxide of hydrogen is formed, and remains entangled in this porous oxide; in fact, it is difficult entirely to remove it. The plate, with this oxide on it, may be dried at ordinary temperatures and exposed to the air for a day or two, and the oxide is still active, or it may be dried over calcium chloride or even exposed to a vacuum for some time, and is still active, but, if heated to 55° for seventeen hours, then its activity is gone, and a picture the reverse of the former one is obtained; that is, the oxide is now quite inactive, but the metal itself is very slightly active. Oxides of zinc, cadmium, and magnesium, if wetted with peroxide of hydrogen solution, act in the same way, and retain their activity with great pertinacity.

From the foregoing experiments it is then concluded that hydrogen peroxide is the agent which directly or indirectly causes the changes in the photographic plate.

This investigation has been carried on in the Davy-Faraday laboratory, and I would again tender my best thanks to the managers of the Royal Institution for allowing me to work there. My thanks are also due to Mr. O. F. Blook, who has most efficiently helped in carrying on the above experiments.

W. J. RUSSELL, Ph.D., V.P.R.S.

#### SOME ANALOGIES OF LIGHT.

BEFORE the Leeds Camera Club, on Wednesday evening, March 22, Mr. E. Heywood lectured on "Some Analogies of Light," illustrated by lantern views. Mr. Heywood drew the attention of the members to the absolute necessity of every photographer knowing something of this power, and the more they studied it the more fascinating did that study become. Light was rapid, vibrating movement, travelling at the rate of 186,000 miles per second, and that during this passage the two great powers of heat and light are detached in their transit, the light travelling at a greater speed than the heat rays. The theories advanced by Sir Isaac Newton and other eminent scientists were dealt with by the lecturer, and he showed that they had formed the groundwork of our existing knowledge. A clearer conception might be obtained by a study of the analogy between the movement of light and that of sound. A tuning fork, on being sounded, has its prongs alternately within their

natural limits and beyond them, so setting up a wave or undulatory motion in the air, which waves, impinging on the ear, convey to the brain the sense of sound, and, in a similar manner, the undulatory waves of light, falling upon the eye, are by the rods and cones of the retina conveyed to the brain, and we receive the sensation of light. The lecturer dealt with the question of colours, showing that these sensations were produced by the amplitude of the vibrations or wave lengths per inch, that the colours of the different parts of the spectrum gave different vibrations, and it was owing to these differences that the eye became perceptible of certain colours within a given range. Although it was known that rays did exist above and below those of the visual spectrum, yet, the eye not being adapted to receive them, no sensation of light was produced. The iris diaphragm, as used by photographers in their lenses, was a copy of the natural diaphragm in the human eye, which opened or closed to accommodate the eye to the amount of light it should receive; and just as an excess of light falling upon the sensitive plate kills, so to speak, the image, so would excess of light kill or tire the nerves of the eye, nullifying the action of the rods and cones of the retina, which are the receivers of light by the eye. Many and varied are the actions of light, and the experiments of Dr. W. J. Russell were fully dealt with, and illustrated by a series of slides which that gentleman had very kindly lent to the lecturer, these experiments showing that many substances, such as printers' ink, zinc, wood of certain kinds, &c., would affect the sensitive plate placed for a day or two in contact with them in the dark room, though no sensation of light was conveyed to the human eye. The theories advanced to account for these phenomena being dealt with, photographers, said the lecturer, must therefore see at once the importance of what they did with their plates between the time of exposure and development. The analogy as between the eye and the camera was explained. A slide was thrown on the screen showing the relative value of vibrations of light in relation to their effect upon the sensitive plate, and it was by making use of these factors we are enabled to use a red light in the dark room. Many other interesting facts were explained.

#### THE "MASSEY" FIELD AND STUDIO STAND.

Messrs. MARION, of Soho-square, are introducing this handsome and effective stand, which is exceedingly well made and finished in the best polished mahogany, the legs being of polished ash, with solid brass fittings. Its total weight is twenty-two pounds. It can be folded up like

Fully extended, height 6 feet 3 inches.

an ordinary tripod, or easily taken to pieces. It is both a studio stand and a field tripod, is quite rigid in any position and cannot slip, and is useful for a variety of work, viz., at home portrait work (especially when

at its lowest for children, dogs, &c.); groups outdoors, especially crowded scenes; cinematograph work; lantern work; while, in addition, it may be used as an ordinary tripod stand for all work, either in the studio or out of doors. The detachment of the centre box on pillar leaves an ordinary tripod stand which will carry any size camera. It is quickly adjusted to any height, and the camera can be tilted either way. It is

At its lowest, height 2 feet 9 inches.

provided with a slotted arc in the top board, so that the direction of the camera can be altered without moving the tripod.

It is obvious that the uses to which a strong, rigid, and well-made stand of this character can be put are so many and important, that a professional photographer would find it a very remunerative investment. The Massey stand is one of the best and most efficient pieces of photographic apparatus that we have recently seen.

#### INTERNATIONAL PHOTOGRAPHIC EXHIBITION AT BIRMINGHAM.

The following are the Judges' awards at the above Exhibition:—

CHAMPION AWARDS.—Gold medal, No. 274, Mr. Robert Ayton, Edinburgh; silver gilt medal, No. 916, Mr. John M. Whitehead, Alva, N.B.; silver medal, No. 854, Mr. Charles M. Wane, Edinburgh.

A.—Landscape.—Silver gilt medal, No. 24, Viscount Maitland, London; silver gilt medal, No. 68, Mr. Robert Ayton, Edinburgh; bronze medal, No. 130, Mr. William A. Fraser, U.S.A.

B.—Seascape.—Silver medal, No. 181, Mr. Charles F. Inston, Liverpool; bronze medal, No. 191, Mr. Ernest G. Boon, Italy.

C.—Portraiture, Figures, &c.—Silver gilt medal, No. 239, Mr. W. Weimer, Austria; bronze medal, No. 220, Mr. Pirie Macdonald, U.S.A.

D.—Architecture.—Silver medal, No. 399, Mr. Charles S. Baynton, Birmingham; bronze medal, No. 409, Mr. Walter W. Hollingsworth, Birmingham.

E.—Ladies' Work.—Silver medal, No. 476, Eleanor M. Grey, Edinburgh; bronze medal, No. 457, Alice Baird, Hova.

F.—Beginners.—Silver medal, No. 534, Mr. E. R. Collins, London; bronze medal, No. 523, Mr. Hugh Lewis, Birmingham.

G.—Special.—Silver medal, No. 650, Mr. Ralph R. Rawkins, London; bronze medal, No. 633, Mr. Alfred Holmes, Bradford.

H.—Hand-camera Work.—Silver gilt medal, No. 794-797, Mr. J. Kearney, jun., Liverpool; bronze medal, No. 803-806, Mr. Ernest G. Boon, Italy.

J.—Instantaneous.—Silver medal, No. 851, Mr. W. J. Croall, Edinburgh; bronze medal, No. 838, Mr. C. E. Walmsley, Ambleside.

K.—Flowers, Fruit, and Still Life.—Silver medal, No. 905, Mr. Henry Troth, U.S.A.; bronze medal, No. 898, Mr. William J. Cassard, U.S.A.; extra bronze medal, No. 936, Mr. Walter W. Hollingsworth, Birmingham.

#### SPECIAL PRIZES.

Hand camera, for largest exhibit, Mr. J. C. Warburg, London.  
Hand camera, for best enlargement, No. 24, Viscount Maitland.  
Adams & Co.'s prizes, 5l. 5s., No. 776, Mr. Charles Speight, Kettering; 5l. 5s., No. 700, Mr. H. W. R. Child, London.  
Griffin & Sons' "Velox" prizes.—2l. 12s. 6d., No. 405, Mr. Freeman Dovaston, Oswestry; 1l. 11s. 6d., No. 268, Mr. Amilius Clarke, Bethesda; 1l. 1s., No. 647, Mr. Harold Hill, Sheffield.

## THE PRESERVATION OF NEGATIVES.

THERE is very little doubt that, in the present age of cheapness, photographers have become, as a rule, very negligent in the matter of the preservation of their negatives. Photography has become so popular with the multitude that they are constantly sitting for their pictures, and consequently all but the latest sitting become out of date. Hence photographers deem their stock of negatives of so little value that, in the majority of cases, they are not even varnished. In the old wet-collodion days, it was an absolute necessity to varnish, as the film was too tender to manipulate without a protective coat. Gelatine is not so easily scratchable, and can be retouched upon without varnishing, it is true; but it should be borne in mind that the film of gelatine, if left unprotected, is more liable to attract damp, and to spoil in consequence. P.O.P., either gelatine or collodion, is not so likely to cause silver stains on the negative as albumenised paper; but still occasions do arise when such a stain occurs, and only those printers who have had the misfortune to let an unvarnished gelatine plate get wet while printing can realise the difficulty that arises, in the first place, to get the gelatine paper off the gelatine negative, and afterwards to get rid of the stain which is left. Then, again, supposing negatives to be stored away unvarnished in a damp place, how easily they may become spoiled, and if a sitter should die, or become celebrated, or any of the hundred-and-one eventualities occur, that may at any time, so as to render the negative of that sitter a valuable property, that special negative is sure to be the spoiled one. Negative varnish is not an expensive commodity, and is not used in any large quantity; still, if photographers, who are working cheaply, must cut their expenses as well as their prices and look upon the purchase of varnish as an unnecessary expenditure, they can make it for themselves at a minimum of cost. I do not refer to retouching varnishes which are made from secret formulae, and which should always be used for high-class work, but to a mere protective varnish, to render the film unscratchable and to protect it from atmospheric influences.

If cheapness is a desideratum, twopennyworth of white hard varnish, obtained from the nearest oilshop and diluted with a pint of methylated spirit, will give a pint of negative varnish for sixpence; this is a protective varnish from damp, silver stains, and scratches, but the negative will not bear printing from in hot sunshine, as it will become sticky. A very good varnish similar to the generality of those on the market may be made as follows:—

Gum sandarac .....	1 ounce.
Seed lac .....	1½ ounces.
Alcohol .....	18 "

But for hardness and power to withstand damp as well as heat I can heartily recommend the following formula, which I do not think has ever been published before:—

Gum sandarac .....	2 ounces.
Gum benzoin .....	2 "
Seed lac .....	1 ounce.
Methylated spirit .....	40 ounces.
Ether .....	1 ounce.

When thoroughly dissolved, add one ounce of oil of lavender and shake up well, allow to stand for a day, and filter off for use.

Whether varnished or otherwise, all negatives should be packed away, in plate boxes, after being numbered and registered, in as dry a place as possible, and, if unvarnished, care should be taken that they be not packed where mice can get at them. It is not generally known that mice have a very great liking for gelatine, but it is, nevertheless, a fact, as I have proved to my cost. I once developed a batch of about a hundred view negatives taken in Paris, and, not having sufficient drying rack accommodation, I set them up for the night around the studio; in the morning every plate was covered with feet marks of mice, all nibbled round the edges, and in one or two instances nearly the whole of the gelatine image eaten off the glass.

Where very valuable negatives are concerned, they should never be packed away until a good transparency has been taken, so that, in the event of any accident occurring to the original negative, a duplicate may be made at any time. Negatives which have been intensified with mercury are at the best unstable; but, before storing away, or, in point of fact, immediately after treatment with mercuric bichloride, they should be soaked in a solution of sulphite of soda for at least thirty minutes, as a mere blackening of the image is not sufficient to secure permanency.

C. BRANGWIN BARNES.

## THE CAMERA IN THE BATTLEFIELD.

UNDER the management of the Kingston and District Photographic Society, Mr. René Bull, the war artist and correspondent of *Black and White*, was engaged to give his display of upwards of 250 photographs of the recent Soudan campaign, the battles of Atbara and Omdurman and the taking of Khartoum, and on the 7th ult. he faced a large assembly in St. James's Hall. Mr. Bull has been busily engaged in displaying these views in various places, and always with the most gratifying success.

Photography is quite a new feature in the work of depicting battle scenes, and will probably supersede the war artist's pen and pencil in

uture because of the more faithful realistic pictures it conveys. Mr. Bull had a hand camera with him in his expeditions with the army, and used it with such skill and effect as to obtain results far beyond anything which an artist with simply pen and pencil could achieve. Battles by photography would have appeared a preposterous idea a few years ago; even now it seems incredible; but these are the days of marvels, and it is not improbable that combats in the near future will be depicted with the cinematograph in conjunction with the phonograph or some similar instrument, thus enabling all the sights and sounds of war to be witnessed and heard at entertainments at home. Still, however commendable battle photographs may be, the greatest admiration is due to the artist responsible for them. To manipulate a hand camera in the face of the enemy with the necessary care and skill shows that the operator is a man of great nerve, and such Mr. René Bull undoubtedly is. Several of his snap-shots were taken whilst with the fighting force when within 400 yards of the enemy on the plain. Within such distance of the foe a man's hand is inclined to become unsteady and unfitted for the delicate art of photography; but Mr. René Bull apparently had no such tremors. Not a single glimpse was afforded of the enemy in the act of fighting, so that the views were entirely of hostilities as witnessed on the English side, which might have been disappointing to some of the audience. If the proprietors of the journal represented by Mr. René Bull had acted in accordance with its title and had had a black snap-shotter with the Dervishes, the deficiency might have been met, but that was perhaps impossible. But, if any disappointment was experienced, it was fully compensated for by the general excellence of the views, some of which were indeed magnificent. In addition to exhibiting fine pictures, Mr. René Bull showed fine descriptive powers, particularly in regard to battles, which were recounted with great vividness.

The first series were of operations on the Indian frontier, and were the prettiest because of the lovely scenery through which the British troops passed. The principal views were those showing the Gordon Highlanders besieging the heights of Dargai; the others were mostly of minor incidents of the campaign, such as burning native villages on the hill-sides, field batteries in action, and the Bengal Lancers and their horses descending precipitous rocks. The horrors of war did not escape attention, the audience being shown pictures of the wounded and dying, and, most melancholy of all, the burial of the dead. From the Indian frontier the lecturer turned to the Soudan, and a number of views were shown of the construction of Kitchener's railway across the desert. Next came several splendid views of a sandstorm, which Mr. René Bull said he kept photographing until it was close upon him, when he thought it time to put his camera on the ground and sit on it so that he might afterwards know where the instrument was. Life in camp furnished a number of amusing scenes, and then came the battle of Atbara, which the lecturer led the audience up to step by step from the firing of the first shot until the close of hostilities. He observed that it was perfectly impossible to obtain any sleep the night before the battle, as the slightest sounds in camp placed everybody on the alert. Several views showed the terrible work done by the Krupp and Maxim guns, which shot away portions of the enemy's zareba and stockades, and the trenches behind were soon filled with dead Dervishes, who, as they lay, looked more like bundles of rags than anything else. The guns had been pounding away at the enemy for over an hour when the infantry charged the enemy, and even then they were run forward in lines pouring forth their deadly hail right up to the foe's zareba. A view of the battlefield with the dead and the dying afforded the lecturer an opportunity of controverting the allegation that wounded Dervishes were massacred by the British. The final series of views were in connexion with the battle of Omdurman, which was finely described by Mr. René Bull. One view showed the British line busily engaged in firing upon the enemy, and another depicted the splendid stand made by Macdonald's men against overwhelming odds. A scene depicting the Sirdar directing the battle produced much applause. The arrival of the troops in Omdurman, the Mahdi's tomb, Gordon's palace, and the memorial service at Khartoum were the subjects of the succeeding views, and the lecture fittingly concluded with an excellent photograph of the Sirdar.

## A NEW FORM OF PHOTOGRAPHIC TELESCOPE.

PROFESSOR E. C. PICKERING, of Harvard, has made a strong plea in favour of certain new methods of conducting astronomic work. A great number of very large telescopes of nearly the same form, he says, have been given to observatories during the last few years. Although such instruments are indispensable in a limited number of investigations, yet, when the latter are divided among so many telescopes, the results obtained by each are often disappointing to the donors. These instruments have been erected, says *The Scientific American*, with two or three exceptions, in places selected from local or political motives, and without regard to meteorological or astronomical conditions. For this reason the great observatories of the world are near large cities or universities where the very conditions that have rendered the countries great have rendered them unfit for the most delicate astronomical research. Nine-tenths of these instruments are in the temperate zone in Europe and the United States, while the southern hemisphere has been entirely neglected and

many of the most interesting parts of the southern sky have not yet been examined by a modern telescope of the largest size.

This duplication of expensive instruments in unsuitable localities is rendered still more objectionable by another condition. All the telescopes are similar in form, their focal length being from fifteen to eighteen times the aperture, and therefore all are best adapted to the same kind of work. In view of these numerous precedents, it was a bold step to deviate from it. But this step was taken, and taken by a woman, Miss Catherine W. Bruce, of New York, who gave \$50,000 to the Harvard College Observatory to construct a telescope of 24 inches aperture, in which the focal length should be only six times the aperture. Fortunately, this experiment succeeded, and the Bruce photographic telescope is mounted in Arequipa, Peru, in a climate unsurpassed, so far as is now known, for astronomical work. Its immediate results are charts, each covering a large part of the sky and showing such faint stars that 400,000 appear upon a single plate. By its aid many new stars of the peculiar fifth type have been found in the Large Magellanic Cloud, showing an additional connexion of this object with the Milky Way. A group of forty nebulae, hitherto unknown, has been found in another part of the sky. The most important work of the Bruce telescope, however, is that every year it sends hundreds of photographs to the great storehouse at Cambridge. Besides the immediate discoveries made from these plates, they, doubtless, carry with them many secrets as yet unrevealed, and many images of objects of the greatest interest yet to be discovered. A striking example of this kind is found in the recent discovery of the planet Eros, which, next to the moon, is sometimes our nearest neighbour in the heavens. Calculation showed that this planet must have been near the earth, and therefore bright, in 1894. An examination showed that this object, although not discovered until 1898, had not escaped the Harvard telescopes. Two images of it were found upon the Bruce plates, fifteen upon the Draper plates, and three upon the Bache plates. It can thus be followed through nearly half a revolution. Six images were also obtained in 1896, when it was more distant and much fainter.

These examples show the advantages of trying new forms of telescopes instead of duplicating those now existing. The Bruce telescope is well adapted to investigations in which the focal length is small. It will, therefore, be interesting to try the effect of a great focal length. It is proposed to build a telescope with an aperture of 12 to 14 inches and a focal length of 185 or 162 feet. This telescope would probably be placed horizontally, and the star reflected into it by means of a mirror. The motion of the earth would be counteracted by moving the photographic plate by clockwork. It would thus become a large horizontal photo-heliograph. This method of mounting a telescope for use on the stars was advocated by the writer in 1881, and has been used here since then with successive telescopes of 2, 4, and 12 inches aperture. The instrument here proposed would be adapted to investigations for which a great focal length would be needed, as the latter would be more than a hundred times the aperture. Several such investigations may be suggested, any one of which, if successful, would amply justify the construction of such an instrument.

Professor Pickering says the best instrument now in use for photographing the sun is the horizontal photo-heliograph. It is a small instrument of this form. Under favourable atmospheric conditions, finer details on the sun's surface could be obtained with a large instrument than have yet been photographed. It could also be used in photographing the protuberances, and it should not be forgotten that preparations must be soon made to observe the solar eclipse of May 28, 1900. The new instrument might be useful in photographing the spectrum of the reversing layer and in showing the details of the inner corona. Images of the moon obtained with such a telescope would be more than a foot in diameter, even if printed without enlargement. These would probably surpass the best photographs yet taken. It is possible that good results could be obtained with Jupiter, Saturn, and perhaps Mars. The planet Eros approaches the earth in 1900. This will be a more favourable time for observation than any other until 1927. Careful preparations should, therefore, be made for observing Eros when east and west of the meridian, since the distance of the sun can probably be determined with more accuracy in this way than by any other method of observation yet attempted. This is one of the greatest problems of astronomy, although it was supposed to be solved in the eighteenth century, but it will probably be left until the twentieth century for a practical solution. It is expected that the positions of the adjacent stars could also be determined with this instrument with an accuracy approaching that of the heliometer.

#### KISSING BY CINEMATOGRAPH: AN AMUSING CASE.

At the Newcastle County-court, last week, an action was brought by F. W. Dodsworth, Collingwood-street, Newcastle, against the Rev. B. Stone Spencer, Curate of St. Paul's, Gateshead, to recover 1*l.* 16*s.* in respect of a cinematograph entertainment given at the parish hall of the church.—Mr. D. E. Stanford was for the plaintiffs, and Mr. Hick for the defendant.

Mr. Stanford said the usual charge for the entertainment was 2*l.* 2*s.*, but in this instance they agreed to take 1*l.* 16*s.* On arrival at the hall the plaintiffs' man was asked by Mr. Stack, the vicar, if the pictures to be

exhibited were in order and fit to be shown. The answer was "Yes." The man referred to one picture. This showed a man at one side of the fence tarring it, and a man at the other whitewashing it. They concluded by tarring and whitewashing each other. This, the man said, was "a dirty scene." (Laughter.)

The Judge: One half of it. (Laughter.)

Mr. Stanford: Both.

The Judge: The whitewashing would not be dirty. (Laughter.)

Mr. Stanford added that, towards the close of the exhibition, some pictures were shown which appeared to have created a terrible sensation in Gateshead. (Laughter.) One represented a fisherman sitting under a rock, and three or four properly attired boys who were anxious to bathe. (Laughter.) The boys succeeded in throwing the fisherman in the water. Then there was depicted a scene in a garden, in which there were three seats. Upon the middle one sat a lady. A gentleman came up slyly behind and kissed her. That was the picture objected to as unfit to be shown to the audience.

His Honour: It is an indecent assault. (Laughter.)

Mr. Stanford went on to read a letter from the defendant to the plaintiffs, dated February 16. This epistle said the writer was sorry to have to say that he had to report more than unfavourably of the entertainment. It had been the cause of very serious complaint. There was one picture which disgusted most of the audience. The writer believed that it was the bathing scene, but this he did not recognise at the time—(laughter)—as it was so indistinct. Some mentioned it afterwards, and expressed some surprise that the picture was not stopped. The second part of the programme was not finished. It was stopped because of the picture which was called *Courtship*. The vicar interfered, and told the operator to withdraw it, but the man refused to show any more, and commenced to pack up. The vicar at the outset said, "We are very particular, and not only do we not want anything indecent, but nothing low or vulgar." The man would not give a list of subjects, but said the worst picture was that showing a man tarring on one side of a fence, and another whitewashing on the other side. The picture called *Courtship* had done lot of injury to the parish. He (Mr. Stanford) supposed that the parishioners had been so injured that it would be possible ever to get them redeemed. (Laughter.) This entertainment had been given in many places. At Longhurst the picture was shown, and the Rev. R. Proctor expressed great delight, and said his people were pleased.

Mr. Hick said the case rested entirely upon a question of breach of contract. They objected to one of the pictures, and said it could have been taken out and the entertainment proceeded with.

John Bolton, who was in charge of the apparatus, stated he did not refuse to exhibit. When the kissing picture was stopped, he did not turn to the audience and say that he could see no harm in it. What he did say was that he was extremely sorry that the vicar should have interposed. He was excited when the picture was stopped, but not until then. It was not necessary to swear at the machine, because it was one of the latest. (Laughter.)

Mr. Hick argued that the vicar was perfectly justified in insisting upon having the kissing picture taken out. The vicar objected to kissing.

The Judge: Do you mean that kissing is less known in Gateshead than elsewhere, or that it is so well known that they want to stop it? (Laughter.)

Mr. Hick: I say a picture of the sort at a parish hall is one thing and the same picture at a music-hall another.

The Judge: If you call the picture *Courtship*, it does not seem to me to be indecent. (Laughter.) If the girl were a stranger to the man, then it would be very indecent. (Laughter.)

Mr. Hick: But that cannot be ascertained from the picture. (Laughter.)

The Judge: If it is intended for courtship, where is the indecency?

Mr. Hick: It is not exactly a question whether it is indecent or not, but whether the vicar liked to have such a picture shown.

The Judge: I should be astonished to find that the vicar is such an unreasonable man as you are making him out to be. Here is a machine that cannot be started, when stopped, without difficulty, and you ask me to say that he ought to have it stopped as he chose. He ought to have asked for details beforehand.

Mr. Hick: My instructions are that he did ask for them, but did not get them.

Mr. Stanford: That is not the fact.

Mr. Hick submitted that there was no reason why the entertainment should not have been completed. His contention was that the plaintiffs' man, when told to go on with his performance, ought to have done so. Not having done so, he had broken the contract.

The Rev. J. Stack (Vicar of St. Paul's, Askew-road, Gateshead), said he asked the plaintiffs' man to let him have a look at the pictures, and he said he had not got them. Witness told him that he was very particular, and the operator said he would give him the names of the pictures, adding, "Do you think I would bring anything here that you would not approve of?" He said the worst picture was that which had been mentioned of two men tarring and whitewashing. Witness said that, if that were the worst, he was quite satisfied, but added, "Remember, if there is anything improper I will stop it." He not only objected to things wrong in themselves, but to anything at all vulgar, "such as kissing matches." He mentioned it particularly because it was a common thing in such entertainments. The kissing picture was "a most violent windmill perform-

ance" with their arms in a most elaborate and grotesque style, and was utterly low. When he saw this picture being thrown on the screen he went to the plaintiffs' man, and said, "I told you I would not have anything of the kind, and you must stop it." The operator said, "What for?" Witness replied, "Because I wish it," and put his hand in front of the machine, but did not touch it, knowing that it would have been dangerous to do so. The plaintiffs' man then stopped the machine, and witness told him to take out the objectionable picture and to go on with the next. He declined, and turned and made a speech to the audience, saying: "Our worthy vicar objects to the picture. I suppose he does not approve of kissing. I can see no objection to it." (Laughter.) Witness said, "That is no business of yours; I object to the picture. Go on with your performance." Witness added if "he did not go on with the performance, he would not pay for it." He could bring evidence that the men were swearing at the machine. Besides the kissing picture there was another which people said they were surprised he had not stopped. He prohibited the scene because he did not know what it was coming to. "You never do with these pictures." (Laughter.) The courtship picture is a wild kissing match and nothing else. (Laughter.) They don't court that way at Gateshead; they may in Newcastle. (Laughter.)

The Judge: There are things all right in one place and entirely wrong in another. (Laughter.)

Mr. Stanford said the plaintiffs were not guilty of breach of contract, because it was the vicar, and not they, who stopped the entertainment. His Honour had seen the picture which had been submitted to him, and he did not think that he had found anything wrong in it.

The Judge said he thought it was decidedly vulgar. He had no doubt that part of the audience would have enjoyed the picture extremely, but that was no reason why those who were trying to raise them should not have the right to object. He thought the vicar was within his rights in putting his hand in front and stopping the picture. He could not come to any other conclusion than that the contract was not completed. It seemed monstrous to suppose that gentlemen in the position of the vicar should have no power in their hands in such circumstances, but were to leave it to the discretion of others as to what they were going to exhibit. Judgment must be for the defendant.

### THE PHOTOMETRY OF INCANDESCENT LAMPS.

At a recent meeting of the Franklin Institute, Philadelphia, Professor Arthur J. Rowland read a short paper on "The Photometry of Incandescent Lamps," describing a special plan of using a photometer for directly determining their candle power. He illustrated his talk by a portable photometer, made by the Newark Ornamental Sign and Iron Works, of Newark, N.J. This is a Bunsen photometer or one in which a measurement of candle power is effected by moving a paper with a grease spot on it, backward and forward along a line joining two lights to be compared, until the grease spot disappears. The candle power of one light being known, a measurement of distance to the paper from each of the lights gives the necessary data for computing the candle power of the other one.

The features of the photometer shown were a scale reading directly in candle power, an incandescent electric lamp as a known standard, and an oil lamp as a sort of secondary or intermediate standard.

In operating the device, the incandescent standard is set up in position where lamps candle power is to be determined are afterward put, and the flame of the oil lamp adjusted to known candle power at the other end of the photometer bar. The standard is then removed and other lamps of unknown candle power substituted and measured. By using the oil lamp in this fashion, nearly all the common difficult and tedious processes of photometry are avoided, only one volt-meter is required, and only one adjustment of the electro-motive force given the lamp.

Professor Rowland explained how, from his own experience with the instrument, an accuracy of determination of candle power to within  $\frac{1}{2}\%$  of a candle power in 16 is readily attained in a room not especially darkened for the purpose. That is, a single determination will not be more than  $\frac{1}{2}\%$  of a candle power above or below the true value. This is quite good for a commercial photometer.

## Our Editorial Table.

### THE STEREOSCOPIC SWALLOW CAMERA.

Marion & Company, Soho-square, W.

To meet the growing demand for stereoscopic hand cameras, Messrs. Marion are introducing the "Stereoscopic Swallow," a very neat and efficient little instrument, as we have satisfied ourselves from personal inspection. The outside measurements of the camera are only  $5 \times 5 \times 4$ . It has two paired single achromatic lenses, which have two stops easily adjusted. The finder is situated on top of the camera, and folds down when not in

use. The camera is fitted with a time and instantaneous shutter and a carrying strap handle. There are twelve sheaths for holding the plates. The plates are easily and rapidly changed after exposure, and a small disc at the back of the camera shows the number of plates left to expose. The size of plate used is  $4\frac{1}{2} \times 1\frac{1}{2}$ . The lenses are placed at such close centres that no trimming down of the transposed prints is necessary.

### SALMON'S MULTUM DISH-ROCKER.

Salmon & Son, 169, Hampstead-road, N.W.

This dish-rocker may be employed to rock one or several developing or other dishes simultaneously, enabling the operator to give individual attention to each negative. It is so constructed that it requires no fixing, and it may be used on any table or across a sink with pendulum swinging on either side or in front of the operator. The rocking platform,

thirty inches in length, can be made stationary at will, forming a rigid table. The dish-rocker is constructed for portability. The detachable pendulum, hooking on and off, is the corresponding length of the rocking board. The working parts of the apparatus are hardened and tempered steel centres, allowing of any weight dish being rocked with a minimum of friction.

MESSRS. MARION are issuing a new series of mounts called the B.R. ("bas-relief") in silver-grey, havan, and green. These have a deep sunk bevel, and may be had either of circular or rectangular form, and for mounting photographs singly or in threes. The mounts have a most effective appearance for show-case purposes, and should be very popular with photographers.

MARION'S Simpson Print Washer is now made to take smaller sizes than hitherto, namely 24 quarter-plate or 24 half-plates; the dimensions of the latter size being only  $13 \times 11$ . As is well known, the washer is composed of a series of frames latticed with linen tape placed in a siphoned tank, between which the prints are laid and kept from contact with each other. Each frame has a separate spray of water, and thus has a thorough washing.

### CATALOGUES RECEIVED.

Reichenbach, Morey, and Will Company, 323-327, University-avenue, Rochester, N.Y.

THIS Company, in sending us their catalogue, write: "We are sending you under separate cover our price-lists and catalogue. We would call your special attention to the automatic camera. This is a folding camera possessing many new features."

"Our line of manufacture consists of printing-out papers, glacé (gelatine glacé), collodion (matt collodion), and others, to be added as rapidly as time will permit; also photographic shutters and cameras."

"We shall also soon manufacture transparent films under a new system, which is patented in England, France, and Germany. We are desirous of securing a responsible agent in Europe for our goods."

Jonathan Fallowfield, 146, Charing Cross-road, W.C.

MR. FALLOWFIELD has sent us a cloth-bound copy of his 1898-99 catalogue. Ordinarily the volume runs into 850 pages, but, inasmuch as the copy before us is interleaved throughout with plain paper for memoranda purposes, the bulk of the book assumes truly gigantic proportions. Fallowfield's catalogue stands out as the largest and completest production of its kind. It is, moreover, liberally supplied with many fine half-tone Swantype reproductions from excellent negatives taken with the popular "Facile" and "Premier" hand cameras, and a first-rate picture on Edwards's platino-matt bromide paper, &c. As a guide to photographic purchases, the value of Fallowfield's catalogue would be impossible to exaggerate.

## News and Notes.

**PHOTOGRAPHIC CLUB.**—Wednesday evening, April 5, at eight o'clock. Members' Open Night.

The Hon. Secretary of the Kirkcaldy Photographic Society writes: "Many thanks for inserting my letter re lack of enterprise on the part of dealers, &c. Since it appeared I have been inundated with lists, &c."

**CRIPPLEGATE INSTITUTE.**—We are asked to announce the commencement of a course of twelve practical lectures in Photography on April 7, at seven p.m., specially arranged for amateurs. Mr. C. W. Coe, of Wood's, 2, Queen-street, is the instructor. Full particulars can be obtained from Mr. H. W. Capper, Cripplegate Institute, Golden-lane, E.C.

**MESSRS. MCKELLEN, LIMITED,** write: "May we draw your attention, and that of your readers and the trade generally, that McKellen, Limited, have removed their offices and works from 4, Bull's Head-yard, and 7, Stars-court, Greenwood-street, to new and extensive premises—Mill-street, Long Millgate, to which they request that all communications should, in future, be sent."

**THE CAMERA CLUB EXHIBITION.**—At this Exhibition, which we noticed in our issue of the 10th inst., we omitted to state that Messrs. R. & J. Beck, Limited, of 68, Cornhill, were represented by an interesting exhibit, which included the Frena pneumatic release, the Frena pneumatic flap shutter, a new quarter-plate Frena, a very fine portable developing sink all complete, and other novelties, which attracted great attention.

**CRIPPLEGATE PHOTOGRAPHIC SOCIETY.**—The members of this Society are laying themselves out for a big meeting on Monday, April 10, when Mr. A. Horsley Hinton is going to deliver his popular and instructive lecture on "Practical Pictorial Photography," illustrated with lantern slides and pictures. Early application for tickets is requested. Admission free, but a few seats will be reserved at 6d. and 3d. Application should be made to Mr. Alfred T. Ward, Hon. Secretary, Cripplegate Institute, Golden-lane, E.C.

**THE NINTH ANNUAL DINNER** of the Croydon Camera Club was held at the King's Arms Hotel, Croydon, on Wednesday evening, March 22. The President (Mr. Hector Maclean) and about forty members and friends were present. Songs and speeches followed a capital meal. Replying to the toast of the "Croydon Camera Club," Mr. Maclean drew attention to the Club's forthcoming open Exhibition, and invited members to co-operate with the view of making it a success. A feature of the evening was a speech by Mr. Keathley Moore, who is at the head of the movement for rescuing Croydon Hurst from threatened destruction at the builder's hands.

**MESSRS. TAYLOR, BOXALL, & CO.,** Photographic Artists and Enlargers, of the Enlarging Works and Studios, 98, Lewin-road, Streatham, S.W., announce that they have started business for the production of the highest-class enlargements in carbon and bromide, also finishing and painting in monochrome, crayon, water colour, pastel, and miniature. Mr. Horace Kennerley Taylor has been for upwards of seven years as artist with the Autotype Company and other well-known firms, and for the last two and a half years he has been with Messrs. Bender & Co. (late Bender & Langflier, of Croydon), as head artist. Mr. Charles Boxall has been several years with Messrs. Morgan & Kidd; for six years head enlarger to Messrs. Elliott & Son, of Barnet, and lately with Messrs. Bender & Co. in that capacity.

**EDINBURGH PHOTOGRAPHIC SOCIETY.**—A concert of the highest class was given, under the auspices of this Society, on Thursday evening, March 23, in Queen-street Hall, for the purpose of starting a fund to acquire new and more commodious premises. A large audience assembled and were delighted with the performance, which had been arranged by Mr. J. Warrack, junr. Mr. Warrack was, unfortunately, unable to be present, owing to a bereavement in his family. Mr. A. Eddington, the energetic President of the Society, and Mr. J. S. McCulloch (W.S.), Hon. Secretary, kindly discharged the various duties which would have fallen on Mr. Warrack's shoulders during the evening. It is to be hoped that the Society will now see its way to secure accommodation worthy of its importance in the capital of Scotland, and thus avoid the inconvenience caused by overcrowding at its annual exhibitions.

**THE LATE MR. R. TUDOR WILLIAMS.**—We have to record the death of Mr. R. Tudor Williams, photographer, Monnow-street, Monmouth, who died on Friday, the 10th inst., at the age of fifty-nine, after a comparatively short serious illness, but whose demise, owing to a perceptible decline of health for some time past, was not altogether unexpected. Mr. Tudor Williams was a familiar figure in the town, and the memory of him will long remain. In early life he was a somewhat noted athlete, although short of stature, and his exploits at cricket, tennis, and skating are still recalled by many. He established his photographic business early in the sixties, and was well known throughout the country for his excellent artistic work, Lord and Lady Llangatock, among others, having frequently requisitioned his services. Socially Mr. Williams was remarkable for his geniality and kindly disposition.

**MR. W. H. WALMSLEY,** of Philadelphia, writes: "I notice in your printing of my little article, 'An Aluminium Microscope Stand,' in the JOURNAL of March 3, a typographical error, which makes a rather ridiculous error on my part as it stands. After stating that the stand exhibited at the Quekett Club had been antedated, to my personal knowledge, almost a quarter of a century, I am made to say that the late Mr. Joseph Beck had brought one of same material in the spring of 1894—a very obvious error. I may have inadvertently so written, but my intention was to give the date as 1874, the year in which he actually brought the instrument to America. May I ask you to kindly make this correction and oblige? Two other errors are also to be found, but they are not so serious. For 'duty' paid, 'duly' paid should have been given; whilst to 'stick faster than another' is not quite so intelligible as 'stick faster than a brother,' in my manuscript. I am but too well aware of the wretched handwriting I am guilty of, but our compositors and proof-readers seem to get it right, as a rule, when they put in their work upon it."

We have to announce the death from influenza of Mr. C. H. Imrie, the Hon. Assistant Secretary of the Woolwich Photographic Society, on the 19th inst., after a few days' illness. Mr. Imrie was but twenty-six years of age, and was a draughtsman in the Royal Carriage Department, Royal Arsenal, where they have been working under great pressure for the past three months. He was a Whitworth Exhibitioner, and at the beginning of a promising career. His illness was of short duration, for he attended the Exhibition of the South London Society on its closing (Saturday evening, the 11th inst.), and was at his usual duties on the following Monday until about eight p.m., when, feeling unwell, he consulted his doctor and went home to bed. The influenza was quickly followed by pleurisy and pneumonia, which caused his death on the date mentioned above. The Woolwich Society will miss him very much, for his energy and enthusiasm were unbounded.

A CORRESPONDENT writes to *Nature*: "Being driven past a row of trees, I noticed that their intermittent shadow on the closed eyelids gave rise to a vivid chessboard pattern of red and black squares, arranged horizontally and vertically. These were perfectly regular, each being equal to about one-twelfth of an inch at ten inches' distance. Waving the open fingers in front of the closed eyelids exposed to the sun gave the pattern fairly well, but better by flashing the sun's rays across the lids by means of a vibrating hand mirror. I see about seven or eight squares each way, the outer ones not well defined; but a younger man, who was not told what to expect, described them as more numerous. What structure in the eye gives rise to the phenomenon? It is not caused by the eyelids, because a piece of tissue paper can be substituted, the eyes then being open. If the paper is white, the squares are white and black. The pattern occupies the centre of the field of each eye."

**JUDGE WADDY AND THE AMATEUR PHOTOGRAPHER.**—His Honour Judge Waddy, Q.C., had before him, at Sheffield County Court, on Thursday, March 23, an action in which George Tompkin, described as a clerk, of 36, Fieldhead-road, sought to recover 7s. 6d. from Alfred William Jackson, a policeman, of 52, Richards-road, Heeley. Mr. A. Muir Wilson represented defendant. Plaintiff, who said he was an amateur photographer, told his Honour he claimed 7s. 6d. for an enlarged photograph he delivered to defendant, and which the defendant returned without giving any valid reason for doing so. His Honour: Why do you call yourself an amateur photographer if you are doing that for money? Plaintiff: I am not in business. His Honour: If you are making photographs and selling them and being paid for them? Plaintiff: I mean that I don't earn my living by it. His Honour: It seems so absurd to call yourself an amateur. It appeared that plaintiff did three enlargements for defendant, with which he was so pleased that, instead of 10s. for the three, he paid plaintiff 12s. 6d., thinking they were his own and excellent work. They were, as a matter of fact, done by the Sheffield Photo Company. Defendant did not like the fourth enlarged copy of a larger size, and returned it, with severe criticisms, signing himself "Yours disgustingly." His Honour, with the aid of Mr. Dakin, photographer, examined the enlargement, and, in giving judgment, discoursed on the art of finishing enlarged photographs. He said the plaintiff had been parading as a jay in peacock's feathers (laughter), and appeared to know as much about photography as he (the Judge) or Mr. Wilson, for most of them had dabbled in it. Mr. Wilson: I am a duffer at it. His Honour gave judgment for plaintiff for 3s. 4d., without costs.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 23.—Mr. J. E. Hodd in the chair.

Mr. T. E. Freshwater showed one of Lumière's stereoscopic transparencies in natural colours. They are made by coating the glass plate with a mixture of gelatine and bromide of silver emulsion, sensitising such film with bichromate, printing under one of the three-colour negatives, and developing and staining the film with a dye of the colour which the first negative requires. The film is then coated with a suitable varnish or other preparation to isolate the first image, when the operations of coating with gelatine, &c., as above described, are again gone through, this time printing under a negative representing one other of the primary-colour sensations. In like manner the image so obtained is varnished, and the third negative printed. The effect of this all is that the

three primary-colour sensations are represented on a triple-coated plate or slide, which, by transmitted light, gives in the stereoscope a very faithful idea of the original, provided that care has been taken to accurately register the three negatives in printing.

The Chairman exhibited what he thought must be the champion of meta dark slides, perfectly workable and constructed for plates, with a vulcanite slide, and weighing only some two or three ounces. Vulcanite, unlike xylonite, was not liable to shrinkage, curling, and the like, and was less liable to go wrong.

#### PACKING OF P.O.P.

The CHAIRMAN said he wished to ascertain the opinions of the members upon an occurrence which had recently come under his notice. In October last a consignment of printing-out paper was dispatched to a man in East Africa (Mombassa), reaching him in November. It was packed up in a number of zinc cases, each holding some three or four packets of cut paper, and soldered up, just as similar consignments had been packed for years past. Some of these were opened in January, but the paper was in such a state that the remaining packages were returned in the following month as unsatisfactory. He found that the paper had assumed a rich, evenly distributed mahogany colour, and, on referring the matter to the makers of the paper, he was informed that the depreciation was entirely due to the method of packing adopted, and that the fumes generated by the heating of the acid flux were particularly responsible. He now brought forward an unopened case of the paper, opened it, and examined the paper. This was found to be of a light mahogany colour, but also spotted and marked in a manner which it would be difficult to attribute to the action of fumes. The Chairman could hardly believe it possible, however, that the small quantity of fumes generated would be sufficient to affect the paper in this manner, and penetrating the many wrappings enclosing the paper.

Mr. FRESHWATER thought it would be better to solder metal cases with a resin flux instead of acid, and that the fumes of the latter would render useless sensitive plates, he knew from experience. The effect was fog, patchiness, and other troubles.

Mr. A. HADDON thought that, in any event, it was impossible to say that certain defects he pointed out in the paper were due to soldering. He found that the action was not only in the gelatine, but in the paper itself. To decide the matter once and for all, the best one could do would be to reproduce the conditions, and see what followed. He also recommended that paper of several different batches, not one, be sent out next time, as a means of ascertaining whether all batches alike were affected. It seemed quite possible that the acid fumes would, in the presence of free silver, turn the same to chloride, and, so far from having a disturbing effect, exercise a preserving influence. He did not think that sufficient hydrogen would be set free by the small quantity of acid used to penetrate the wrappings, and one would naturally look to the edges of the paper for the strongest evidence of the action.

The general opinion was that something more than the hydrogen and acid fumes was concerned in such a complete destruction of the paper.

The HON. SECRETARY stated that the Recorder had found it necessary to resign his position. The Committee were therefore asking for qualified volunteers amongst the members to step forward, and it was hoped that this notification might reach such persons and serve to fill the vacancy with as little delay as possible.

#### PHOTOGRAPHIC CLUB.

MARCH 22.—Mr. F. A. Bridge in the chair.

Mr. E. J. WALL, F.R.P.S., gave a chat on various methods of colour photography now in vogue. Commencing with an exhibition of transparencies made by means of Ives's process, he explained the principles underlying the same. The first step is the taking of three negatives, each through a different coloured screen, the result of which is that we have three negative images in monochrome representing the different gradations and colours in the original. Positives of these images are projected, each through its particular colour screen, and blended upon the sheet, the mixture approximating more or less correctly, according to the illuminant and perfection of the manipulation previously brought to bear upon the subject, to the colours of the original design. Baskets of flowers and fruit, and paintings were shown by means of the apparatus, and an interesting analysis followed, showing the peculiar effect of stopping one or more of the lights from the triple projecting lantern. Mr. Wall went minutely into the question of screen-making. Dry screens or tanks containing fluids may be employed. He preferred to make his own, using thin white patent plate glass and cementing two together with Canada balsam. For the red screen, saffronine and chrysoidine; for the violet, ethyl-violet. For the green screen, naphthol green and picric acid. He had been at one time much bothered by marks in his screens, putting them down to drying marks, but he had since found that they were due to microbes, which found time to propagate, seeing that the films of gelatine forming the screens took twelve to eighteen hours to dry. As an antiseptic he found xylol the best. Touching upon the opinions expressed in many high places that different plates were not to be used in three-colour work, he disagreed entirely. With the screens mentioned he used an Imperial process plate, Lumière's yellow and green sensitive plate, and Lumière's series C. Mr. Wall next went into the questions involved, and the essential differences between three-colour work by projection and by printing. Joly's process was then discussed. Much the same as Ives's process in principle, it differs in having a single negative upon which are recorded the three primary colours. It is effected by the use of a screen combining the three colour screens in one, viz., a screen ruled finely and repeatedly in the three colours. The negative is consequently in lines, and the positive, mounted accurately against a screen similar to the taking screen, will, on projection, give the original in natural colours. The peculiar effect of incorrect mounting of the positives and viewing screens was shown at length, and a number of questions were asked and replied to by the lecturer.

#### FORTHCOMING EXHIBITIONS.

1899.

- April 1-May 13 ..... National Trades and Industrial Exhibition, Bingley Hall, Birmingham. Manager, Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.  
 „ 3, 4 ..... Beverley. T. J. Morley, Toll Gavel, Beverley.

#### Patent News.

THE following applications for Patents were made between March 13 and March 18, 1899:—

- ELECTRIC LIGHT.—No. 5514. "Improved Electric-light Apparatus for Taking Photographic Portraits." G. W. MORGAN.  
 PACKING BOXES.—No. 5528. "Processes and Boxes for Packing Sensitised Material." Complete specification. M. J. STEFFENS.  
 PHOTO-PRINTING.—No. 5561. "Improved Means Applicable for Use in the Production of Photo-prints." L. SHAW and J. HALDEN.  
 SHUTTERS.—No. 5623. "Improvements in Camera Shutters used in Taking Photographs." R. MARTIN.  
 BRACKET STAND.—No. 5792. "An Improved Bracket Stand for Photographic Cameras." E. M. M. SMITH.  
 CAMERAS.—No. 5836. "Improvements in or relating to Photographic Cameras." F. J. A. BERINGER.

#### Correspondence.

\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*\* We do not undertake responsibility for the opinions expressed by our correspondents.

#### THE FUTURE OF PHOTOGRAPHIC ASSISTANTS.

To the Editors.

GENTLEMEN,—I am indeed very glad to see you have devoted a half page in this week's JOURNAL to a photographic assistant's future.

In my opinion, as in yours, the outlook is very gloom indeed, unless a Union is established, which is done in almost every other kind of business.

Of course, I quite agree with you, there are a good many assistants who really are not capable, but then there are others who (not from their point of view) are first-class men, and yet cannot obtain berths.

I should very much like to know what employers call first-class men on the whole, as what some call Al workers others do not; also if one has to thoroughly understand every branch of photography before he is a first-class man? Then, it is obvious that they are not young men, although some are quicker at learning than others.

In many cases specimens do not do justice to the man, and one cannot always obtain specimens of one's own work, and I think, if employers will have specimens, it is a great temptation for some to substitute others' work for their own, thereby deceiving the employer.

As you mention, some do not possess the qualifications which they set forth, but I fancy sometimes employers give their verdict before the assistant is given a chance; and, again, I have found from experience that, if one is backward in putting forth his ability, he is judged accordingly.

I only wish you, or some one else, would find your way clear to found a Union. I should do my utmost to show its advantages and increase its members. Then it might be coupled with an employment agency for photographic assistants alone.

I may add before I conclude that I have made up my mind not to forward what remaining specimens I have, as I have lately lost two sets, and I think it most abominable of those who detain them, showing clearly their true character. I only wish all assistants would abstain from sending their specimens, as I think only a trial is fair.

Trusting this will not cover too much space, and thanking you exceedingly for your kindness,—I am, yours, &c., F. S.

To the Editors.

GENTLEMEN,—Re your article in this week's JOURNAL on the above subject, a year or so back I was a retoucher in the employ of a firm of photographers who do a large trade, and whilst so employed came into touch with many of their assistants, so I think my remarks, which are from practical experience, will be of some interest to the many assistants who have been complaining to you of the dearth of employment. To let a little light on the system which this firm works, to fill up vacancies for operators and retouchers on their staff, it was the

rule (and I am told that the rule is still in force) to engage a few smart lads, teach them retouching, and, after a few months' training, to pack them into the first vacancy at very small wages (14s. or 15s. per week); and it so happens perhaps (it often has) that the operator at the branch to which this raw recruit is sent is discharged or leaves. In the meantime this lad has learnt to take a negative, and to save money he is given the vacant post, and thus becomes a full-blown operator. I have also known lads after printing proofs for a few months leave and try for a birth as a "first-class printer." But the real point is, after serving this firm for a time, these assistants fancy they are, shall I say? photographic experts, leave to obtain more money, and so help to fill the ranks of the unemployed "first-class operators and retouchers," and of course another lad is drafted into the "expert's" place, and so the game goes on. After this, can any one wonder at the photographic labour market being overstocked with "first-class assistants?" You, Gentlemen, have indeed hit the nail on the head in the closing remarks of your leader, i.e., "We are sorry to say employers who have second and third-rate studios, and in some instances doing a fair trade, have no more actual knowledge of photography than the assistants they employ." This is only too true.

With regard to salary, it might also interest you, Gentlemen, and your readers, to know the average salary paid to operators and retouchers on the staff of this firm under notice: Operators, 25s. to 30s., in some cases 35s. per week, with "com.," after deducting a large amount for working expenses. Duties of operator (thirty to forty sittings a day), retouch, develop, and, in short, to make himself generally useful. In case of boy operators the salary is smaller. Retouchers, boys, 14s. to 15s.; retouchers, 11. to 25s. up to 28s. They are expected to retouch thirty negatives per day, including heads. For this magnificent salary they have to work eleven hours per day, open on all Bank holidays, including Good Friday. No summer holidays; in fact, no break from one year's end to another. Who would not be a "first-class assistant" under the above conditions?

It would be interesting to have the opinions of your readers on the salaries, &c., given above. Trusting you will find space for this letter, and thanking you for your very able leader, — I am, yours, &c.,

London, March 25, 1899.

G. H. D.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

G. S. Ellis, 12, Albert-street, Mansfield, Notts.—Three cabinet photographs (busts) of Rev. C. H. Goodman, Tikonko, West Africa.

Rev. C. Steele, Leavenhath Vicarage, Colchester.—Photograph of young pig with one fore part, but two complete hind parts. The pig stands on six legs, and on the back, at the junction of the two hind parts, a single shank grows out, but this shank has two perfect feet.

W. W.—Dorking is the last address we can trace.

G. E. B. (Swindon).—Impossible now to trace the source.

W. H. W. (Philadelphia).—The complete report is obtainable from the Society of Arts, John-street, Adelphi, London, W.C., for one shilling and postage.

M. A. MEYER-BURKLY.—1. Better address Messrs. Newton & Co., 3, Fleet-street, London, E.C. 2. About forty of the leading English photographers are sending about 100 very fine photographs to the Exhibition. By all means visit it.

APPRENTICESHIP.—EMPLOYER. Unless the indentures are duly stamped, you have no hold on the apprentice. He is, *de facto*, a weekly servant, and can leave at any time by giving a week's notice. It is too late now to have the indentures stamped.

ASSISTANT OPERATOR.—There are practically no good books on the subject. Bigelow's *Album of Lighting and Posing* might be obtained second-hand. This would suit you. The Chicago Photo-Beacon Company, Chicago, publish a valuable little book on *Lighting*, by Inglis, price one dollar, postage extra.

COPYRIGHT.—G. F. READWIN (Norwich) says: "I have two negatives, taken for a tradesman in this town, who requires the copyright of same. Will you kindly give me particulars?"—In reply: If the photographs have been paid for, the copyright is your client's; if not, the copyright is yours, and you must make an assignment. We do not answer questions through the post.

ETHER SATURATOR.—S. BIGGS. A good ether saturator is perfectly safe, in careful hands, by those who understand the apparatus and the dangerous character of ether and can safeguard against it. As you seem to have had no experience with the lime light in any form whatever, we should not advise you to purchase a second-hand ether saturator, to begin with at least.

REPRODUCTIONS.—S. SEELEY.—The reproductions by the firm named are, we believe, by a collodion process—not gelatine, but the process by which they are done has not been published. Indeed, we are told it is kept as a profound trade secret, also, that there is little or no hand work on the negatives. We cannot enlighten you further in the matter beyond saying the prints issued are by the carbon process.

FORMULA WANTED.—W. W. says: "Could you give me a formula for making gelatino-chloride emulsion for printing out—one that does not require washing preferred—or an albumen-chloride emulsion for the same purpose? If not, can you give us a house that supplies the same?"—A formula for gelatino-chloride emulsion printing-out paper, is given on page 1040 of the ALMANAC. We know of no albumen-emulsion paper for the purpose. Mr. S. H. Fry, 12, South-villas, Camden-square, N.W., might supply the gelatine emulsion.

STUDIO BUILDING.—R. T. OWEN says: "Should be greatly obliged if you could answer me the following questions:—1. What is the best angle or pitch for a studio roof? 2. Should studio face exactly north? 3. Is there any book or plan to be obtained on studio construction?"—In reply: 1. There is no best, because ideas vary very considerably on the subject; one prefers one angle, and one another. A good slope to the roof is, however, desirable to throw off water and snow. 2. A north aspect is easier to work than any other, but equally as good results may be obtained in any other. 3. Mr. Bolas has written a book on the subject, which may be obtained from Marion & Co., Soho-square.

SPOTS ON NEGATIVES.—J. JARVIS says: "I have a lot of negatives recently taken. I have taken one print only from each, and find them covered with innumerable yellow spots, as though damp paper had been used. Ready-sensitized paper quite dry was used. There is no metallic reduction in the film, which is the case with damp paper. The negatives were unvarnished."—We should suggest treating the negatives with a tolerably weak solution of cyanide of potassium in one part of water to two of alcohol. If the stains are on the surface of the film, this will probably remove them. If, however, they are in the film, we fear there is no remedy. But, as we have not seen the negatives, we can give no very positive opinion.

OPERATOR'S AGREEMENT.—B. W. G. The agreement would, doubtless, be binding if you signed it, but we should recommend you to hesitate before doing so. It seems all on one side, and that not on yours. How far the clause binding you not to enter the service of another photographer, or practise photography on your own account, within so wide a radius, would hold good in a court of law is very doubtful. Unquestionable agreements are void, and the proposed agreement would, we suspect, be looked upon as an "undue restriction of trade," which is against the law. Any how, we should not advise you to sign any agreement unless you morally as well as legally intend to abide by it. As we have said before, it is a very one-sided one, particularly for the small salary to be paid.

DETENTION OF SPECIMENS.—EVIDENTLY ONE OF THE MANY says: "Some time ago I sent to you specimens of my work, together with full particulars of my ability and experience, asking your opinion of same. Your reply was to the effect that I could easily command a salary of 21. 2s. per week. Since then I have sent in several applications in reply to advertisements in the JOURNAL, but all to no avail. A month ago I sent the same specimens as I had forwarded to you to —, asking somewhat less salary. To this day I have not heard from him, although I have written for the return of my specimens, postage being enclosed in the first instance. This week I have sent in two more applications, and have had to excuse myself for not sending specimens. Can it be possible that any one should take a month to decide upon an applicant? If this be the case, I am afraid his business aptitude is not to be envied. Do you know the house at all, as I do not wish to think he would detain property other than his own?"—In reply: We do not know the man. A threat of legal proceedings should be made at once. An employer who detains specimens renders himself liable to an action for damages.

PHOTOGRAPHING TROTTERING HORSES.—A. N. BOYLE says: "I have a commission to photograph, whilst trotting, a tandem equipage, and am doubtful whether I can obtain sufficient exposure with the lenses I possess. The fastest rapid rectilinear lens I have is at quarter-plate T. T. & H. D. lens, working at f-8. I have also a Voigtlander portrait lens (cabinet) which gives approximately an aperture of f-9; but, as this lens is of a form about twenty years old, I doubt whether I should get sufficiently good definition with it, its depth of focus being very slight. Would a Cooke No. III 5-inch f-6.5 lens be rapid enough for such a subject travelling at right angles to the camera, or would a Ross 6-inch Symmetric Anastigmat f-5.6 be better? I could not afford a Zeiss or Goerz lens. Any hints as to exposure and development would be very acceptable. I wish to take the subject on a quarter-plate to enlarge to 10 x 8, using for exposure a T.P. focal plane shutter. Time of day between 11 a.m. and 1 p.m. and in sunlight if possible."—The quickest lens you have is undoubtedly the Voigtlander, and the fact that it was made twenty years ago need not militate against its definition. Of course, the larger the aperture, the less "depth of focus" it has; but the Voigtlander, being a "cabinet" lens, is of longer focus than any of the others, and therefore may be expected to cover the plate better with a large aperture. If stopped down to the same aperture as either of the others, it would have the same depth of focus. Either of the brands of plates named are very rapid. Better use with them the developers recommended by the makers for rapid exposures. You ought to experience no difficulty in getting a good result.

\* Several answers to correspondents and other matters are unavoidably held over till next week.

## EX CATHEDRÂ.

It was stated in our Foreign News and Notes last week, and had been previously announced, that the Chemische Fabrik, late E. Schering, in conjunction with a paper-manufacturer in Germany, had succeeded in producing a suitable paper for photographic purposes, when it has to be “surfaced” with the baryta coating, as for the gelatine printing-out papers or for collodio-chloride. Having accomplished that, they found themselves handicapped by the fact that the “ring” had bound those who coat the paper with the baryta not to coat any other papers made outside its body. However, it appears the Chemische Fabrik has proved itself equal to the occasion, and is now able to put upon the market a collodine paper of its own manufacture throughout. It is to be hoped that this firm will not stop at that, but will supply the baryta-coated paper for use to others. How much longer it may be again asked, will English paper-makers and surfacers of it allow the photographic paper-manufacture for the whole of the world to remain in the hands of one or two German houses?

In the old days of photography, when the photographic image was more in the paper than on its surface, as in the calotype and analogous process, and purity of material was the great essential, English-made papers were pre-eminent. With paper for albumenising, purity of the paper and more particularly its surface is the essential, but with modern emulsion photography—gelatine and collodion—the baryta or other coating is the chief point for consideration, so long as the paper itself is tolerably free from impurities and is sufficiently hard and strong to withstand the washings, &c., the prints have to undergo. One can quite understand that large firms, with a file of orders in their own special lines—and the paper trade is very brisk just now—will not go out of their way to experiment with photographic paper-making. But there are many smaller factories, we should imagine, who would find it worth while to take up the matter, particularly seeing that, if the experimental paper did not answer for photography, it would be saleable for other purposes. There are many papers now in the market that would, doubtless, answer if they were suitably coated with the baryta. If so, then it simply resolves itself into applying the coating. Here, then, is a chance for English paper-surfacers, or “enamellers,” and a fortune awaits them from English consumers alone.

\* \* \*

ACCORDING to *Science*, a new method of photographing in natural colours has been discovered by Professor R. W. Wood, of the University of Wisconsin. The colours are said to be obtained by diffraction; and, though at present the production of the first finished picture is somewhat tedious, duplicates can be printed as easily as ordinary photographs are made. The pictures are on glass, and are not only colourless but almost invisible when viewed in ordinary lights, but, when placed in a viewing apparatus, consisting of a convex lens on a light frame, show the colours of nature with great brilliancy. The principle is that the picture and the lens form spectra which overlap, and the eye placed in the overlapping portion sees the different portions of the picture in colour depending on the distance between the grating lines at that place. Professor Wood says the finished picture is a transparent film of gelatine with very fine lines on it, about 2000 to the inch on the average. The colours depend solely on the spacing between the lines, and are pure spectrum colours, or mixtures of such, the necessity of

coloured screens or pigments, used in all other processes except that of Lippmann, having been overcome. The pictures can be projected on a screen by employing a suitable lantern, or can be viewed individually with a very simple piece of apparatus consisting of a lens and perforated screen mounted on a frame. We agree with a remark of our contemporary, *Nature*, that it is difficult to form an opinion upon the method or results from the information so far available, and we hope that further details will soon be published.

\* \* \*

A NOVEL suit in connexion with radiography has been brought before the Civil Tribunal of the Seine, says the Paris correspondent of the *Standard*. A lady sued a radiograph specialist for 200*l.* as damages for serious burns in the course of an operation in which the Röntgen rays were brought into use. It was stated that the patient was suffering from some internal complaint, and it was decided that, as she was averse to an operation, radiographs of the affected parts should be obtained, the better to judge of the nature of the disease. Three were taken, one with forty minutes' exposure, the second with forty-five minutes', and the third with an exposure of an hour and a quarter, but with a negative result in all instances. After the second exposure, it is stated, the skin was wealed, as if it had been burnt, causing, in a few days, a painful wound and great suffering. For this the damages were claimed. It is tolerably well known that the continued action of the X rays on the cuticle of different individuals varies greatly. In the medical evidence called for the defence, one doctor said that the exposure of one hour could be endured by ninety-nine persons with impunity, while with the hundredth burning would ensue, even with a quarter of an hour's exposure, in the same way that some persons could absorb a gramme of morphia without ill effect, while others would be poisoned under similar conditions. In the end the Court reserved judgment, and it will be interesting to see what that will be.

\* \* \*
